1 Introduction

On March 12, 2026, Prairie Song Reliability Project LLC (Applicant) received an email Request for Information (E-RFI) from California Energy Commission (CEC) staff for the Prairie Song Reliability Project (Project) (Docket Number 25-OPT-02). Table 1 lists the E-RFI responses provided in this document. Responses are provided in Chapter 2.

Table 1. Data Responses Provided Herein

E-RFI Request Resources Area	E-RFI Request Numbers
Public Health	E-RFI-1 through E-RFI-8

2 Public Health Responses

2.1 Request for Information 1

E-RFI-1. In the modeling files, two different types of sources appear to have been defined. Line source (BLINE1) and four point sources (SUB1, SUB2, FIRE1 and FIRE 2). Please clarify which source type was used in the thermal runaway plume simulation. If the other sources are not used in the thermal runaway plume analysis, please clarify how they are used in other parts of the analysis.

E-RFI-1. RESPONSE: The supplemental plume analysis provided as Data Request Response 1, Attachment 9, Appendix 3.9B, modeled a battery energy storage system (BESS) container venting during a thermal runaway event as a point source (see TN: 265874, docketed on September 4, 2025; hereinafter, “September 2025 Plume Analysis”). The location was selected to provide a worst-case scenario based on the predominant wind direction. The specific parameters are identified in Table 2, AERMOD Principal Parameters – Thermal Runaway Analysis of the September 2025 Plume Analysis, with complete model results provided as Attachment B to the September 2025 Plume Analysis.

On February 20, 2026, the Applicant submitted a third plume analysis in response to Information Request REV 2 DR PH-2 issued by CEC staff (see TN: 268721, Data Request Response No. 5, Attachment 1; hereinafter, “February 2026 Plume Analysis”). The AERMOD dispersion analysis in the February 2026 Plume Analysis modeled emissions as a buoyant line source (BLINE1), rather than a point source. This is confirmed in the .SUM and .ADO files for each model run included in Attachment B to the February 2026 Plume Analysis (see pages 38 and 108 for the large scale burn test [LSBT] model run, and pages 155 and 2,378 for the full unit model run). The specific parameters are identified in Table 2, AERMOD Principal Parameters – Thermal Runaway Analysis, of the February 2026 Plume Analysis, with complete model results provided as Attachment B to the February 2026 Plume Analysis.

For the February 2026 Plume Analysis, the Applicant used a buoyant line source rather than a point source because it more accurately represents the physical configuration, release mechanism, and thermal characteristics of emissions generated during a containerized BESS fire. In a containerized BESS fire scenario, combustion gases and battery decomposition products are released through multiple roof-mounted vent panels distributed along the length of the container, rather than from a single, discrete exhaust point, consistent with how a thermal event would move through each cabinet and release out of the top of each cabinet versus how a point source typically represents the emissions from a single exhaust manifold or tower. When thermal runaway progresses and venting occurs, emissions are released along a linear footprint corresponding to the container roof. A line source configuration allows emissions to be spatially distributed over this length, whereas a point source would concentrate the entire emission rate and buoyancy to a single location.

The plume rise associated with a BESS fire is driven primarily by thermal buoyancy generated by the fire, not by engineered stack momentum. AERMOD’s buoyant line source formulation is specifically intended to represent elongated, buoyancy-dominated releases, such as roof vents or open industrial structures, where plume rise and dispersion occur over a finite horizontal distance. In contrast, point sources are most appropriate for stacks or isolated vents with defined exit velocities, diameters, and momentum—conditions that are not present during

a BESS fire event. Distributing emissions along a buoyant line source provides a more physically realistic representation of plume development, lateral spread, and dispersion in the near field (see Exhibit 1).

Exhibit 1. Sungrow Power Titan II Large-Scale Burn Test

Note: Image shows release across the entire top of the container after being forced into thermal runaway.

The buoyant line-source approach is also consistent with prior BESS fire plume analyses, and aligns with established regulatory practices for modeling non-stack, thermally driven releases. This approach avoids applying a planned operation's stack-based assumptions to an emergency fire scenario, and ensures that the modeling reflects the distributed nature of emissions during a BESS fire.

Accordingly, the buoyant line source was selected for the February 2026 Plume Analysis because it best represents the distributed roof-vent-release geometry, fire-driven buoyancy, and non-engineered emission characteristics of a containerized BESS fire, and more accurately characterizes the physical release mechanism or dispersion behavior associated with this type of event compared to a point source.

Regarding the use of the four point sources (SUB1, SUB2, FIRE1, and FIRE 2) identified in the data request, these sources were not used in either modeling run for the February 2026 Plume Analysis. As described above, a buoyant line source was modeled to represent a full-unit thermal runaway. The original AERMOD run for the health risk assessment for maintenance and testing of the emergency generators on site was used as a basis for the original plume study. These sources were removed for the February 2026 Plume Analysis, but the site boundary and receptors were kept. The four point sources identified above were only used in the health risk assessment for the emergency generators.

2.2 Request for Information 2

E-RFI-2. None of the sources mentioned above represent the BESS unit closest to the residents. Please provide the justification for the selected source location. If the line source was used, please explain why the source was not located closest to the nearest residence.

E-RFI-2 RESPONSE: The location of the modeled BESS source and the selection of the closest receptor were intentionally chosen to represent a conservative, worst-case exposure scenario based on site layout, surrounding land uses, and site-specific meteorological conditions.

BESS Source Location

The modeled BESS unit location was selected based on review of the 5-year (2016–2020) Palmdale Airport meteorological monitoring station dataset used in the AERMOD analysis, including evaluation of the wind rose derived from the Palmdale Airport meteorological data station and the wind rose of the weather station in Acton. As shown in the Palmdale Airport meteorological data, the predominant wind direction is from the southwest, resulting in potential plume transport toward the nearest residential receptors located along the eastern and northern boundaries of the Project site.

Consistent with this wind pattern and the physical layout of the facility, the modeled BESS container (modeled as BLINE1) was placed at a location within the BESS array that would result in the shortest downwind distance to nearby sensitive receptors under prevailing wind conditions (the northeast corner of the western section of the facility at 394880.53 meters east, 3816417.74 meters north). This placement ensures that the modeled source represents the most conservative container location with respect to potential off-site impacts, rather than an average location or interior location that would increase separation distances and reduce predicted concentrations.

Receptor Selection and Closest Receptor Identification

A comprehensive receptor network was developed to capture potential near-field and far-field impacts, consistent with Office of Environmental Health Hazard Assessment (OEHHA) and regulatory air dispersion modeling guidance. The receptor grid provided the following:

- Dense receptor spacing along the Project fence line and immediately outside the facility boundary (25-meter spacing).
- Progressively coarser spacing with increasing distance from the source, extending to a 6-mile radius.

The closest off-site residential receptor, identified as the maximally exposed individual receptor (MEIR), is approximately 89 meters (approximately 292 feet) from the modeled BESS container (394942.29 meters east, 3816484.92 meters north). This receptor corresponds to the nearest residential land use downwind of the BESS under predominant wind conditions and represents the location where the highest ground-level concentrations are predicted to occur.

Model results confirm that the highest 1-hour and 8-hour concentrations for the modeled scenario occur at this closest receptor. All other receptors evaluated in the modeling domain exhibited lower predicted

concentrations. Accordingly, use of this receptor for health risk and air quality evaluations provides a conservative and protective assessment of potential public exposure.

2.3 Request for Information 3

E-RFI-3: Attachment A of DRR 5 indicates that the off-site nested receptor grid was established with spacing of 25 m, 50 m, 100 m, etc., as summarized in the table for “Receptors – Off-Site Nested Grid”. However, the receptor definition file (ROU file) provided does not appear to include receptors with these spacing. Please confirm whether the correct receptor file was provided. If not, please submit the correct receptor file.

E-RFI-3 RESPONSE: There were two model runs performed in the February 2026 Plume Analysis: a full-unit run and a large-scale burn test (LSBT) run. The full-unit run modeled the concentrations of an entire BESS unit undergoing thermal runaway. The LSBT run was used to develop a scaling factor to apply the results of the LSBT emission results to the Project site.

The receptor grid identified above in the E-RFI-2 response was used for the full-unit thermal runaway model. For the LSBT model run, only the MEIR and two discrete cartesian receptors (one at 10 meters downwind and one at 20 meters downwind) were used for scaling the LSBT results to the Project site. The remaining receptors on that model run were property boundary receptors to maintain the same property boundary as the full-unit model run. The other receptors (as well as the property boundary receptors) were not needed for the purpose of scaling the LSBT results, and therefore were not included.

For the LSBT model run in the February 2026 Plume Analysis, the MEIR location was not in the same exact location as the MEIR in the unit model run. Therefore, the Applicant has revised the plume analysis to match the MEIR location for the LSBT model run with the MEIR in the unit model run. This slightly changes the AERMOD 1-hour MEIR concentration in the LSBT run to 134.29 micrograms per cubic meter/grams per second ($\mu\text{g}/\text{m}^3$)/(g/s). This resulted in a slightly higher scaler, and the hazard quotient for benzene increased to 0.42 and the hazard quotient for formaldehyde increased to 0.12. However, the hazard index of 0.77 did not change because of rounding. A revised plume study report including these revisions is included as Attachment A (redline version) and Attachment B (clean version).

2.4 Request for Information 4

E-RFI-4: In Attachment A, Table 2 LSFT AERMOD Impact X/Q, the impact at MEIR is stated as 131.27 ($\mu\text{g}/\text{m}^3$)/(g/s), and the impacts at receptors 10 m and 20 m downwind are shown as 14,171.75 ($\mu\text{g}/\text{m}^3$)/(g/s) and 6,493.89 ($\mu\text{g}/\text{m}^3$)/(g/s) respectively. Please provide the corresponding complete AERMOD files, the receptor locations at which these maximum impacts occur, and the meteorology data used for the 10 m and 20 m downwind impacts calculation. Please explain how the meteorological data were processed for this specific modeling analysis.

E-RFI-4 RESPONSE: The results in Table 2 of the February 2026 Plume Analysis are for the LSBT model run. Modeling files were provided to CEC staff via Kiteworks on February 20, 2026. Following a review of the uploaded files, it appears the folder labeled “Prairie Song Plume Study – LSBT” was the incorrect folder. The correct folder that has the results indicated above will be uploaded to Kiteworks as part of this response. In the .AD subfolder of the correct folder (“Prairie Song Plume Study – LSBT 2”), the file labeled “01H1GALL.PLT” dated February 4, 2026, contains the results of the LSBT model run shown in Attachment A, Table 2. The impact at the MEIR of 131.27 ($\mu\text{g}/\text{m}^3$)/(g/s) [revised to 134.29 ($\mu\text{g}/\text{m}^3$)/(g/s) in the “Prairie Song Plume Study – LSBT

2"] is at 394942.29 meters east, 3816484.92 meters north, and the impacts at receptors 10 m and 20 m downwind are shown as 14,171.75 ($\mu\text{g}/\text{m}^3$)/(g/s) at 394887.41 meters east, 3816425.27 meters north, and 6,493.89 ($\mu\text{g}/\text{m}^3$)/(g/s) at 394894.33 meters east, 3816432.43 meters north.

2.5 Request for Information 5

E-RFI-5: In the submitted spreadsheet file, "Attachment A.xlsx," cells E29 and E30 report HF and HCl emission values of 1263.72 mg/kg (before applying 0.5 conservative reduction factor from pouch to cylindrical cells) and 170.43 mg/kg, respectively. These values do not appear to be directly reported in the referenced source, "Liu 2021, Experimental study on thermal runaway and fire behaviors of large-format lithium iron phosphate battery." Please provide the calculations or methodology used to derive these values.

E-RFI-5 RESPONSE: The hydrogen fluoride (HF) and hydrogen chloride (HCl) emission inputs used in the AERMOD dispersion modeling presented in the February 2026 Plume Analysis were derived from the peer reviewed study by Liu et al. (2021).¹

Liu et al. (2021) conducted full-scale thermal runaway and fire tests on 243 amp-hour (Ah) LiFePO_4 (LFP) cells, including ignited fire scenarios representative of worst-case BESS fire conditions. The study directly quantified the total mass of HF and HCl generated per cell during thermal runaway and combustion using FTIR gas analysis (see Table 4 of Liu et al. 2021).

For ignited tests, Liu et al. (2021) report the following measured gas yields per 243 Ah cell, averaged across 50% and 100% state-of-charge conditions:

- HF: 5.45 g per cell
- HCl: 0.735 g per cell

These values represent experimentally measured totals for a single large-format LFP cell subjected to full thermal runaway and flaming combustion.

Normalization Approach

Because the Project will use battery cells with a different rated capacity than the test cell used by Liu et al. (2021), the study results were normalized to the Project using a capacity-based scaling approach, consistent with published battery fire literature and regulatory modeling practice.

HF generation in LFP cells is primarily a function of electrolyte salt mass and polymer content, which scale approximately with cell capacity (Ah) for a given chemistry and form factor. Because the scaling is not a direct correlation but an approximate one, it is important to choose cells with a capacity near the modeled cells to reduce scaling bias. Liu et al.'s test cell and the Project cell share the same chemistry (LFP). Accordingly, emissions were scaled on an amp-hour (Ah) basis.

¹ Liu, Pengjie, Yongqi Li, Binbin Mao, Man Chen, Zonghou Huang, and Qingsong Wang. 2021. "Experimental Study on Thermal Runaway and Fire Behaviors of Large Format Lithium Iron Phosphate Battery." *Applied Thermal Engineering*. Vol. 192, 2021, Article 116949. <https://www.sciencedirect.com/science/article/abs/pii/S1359431121003963>.

HCl generation in lithium-ion battery fires can depend on test-specific factors such as the amount of plastic or PVC components burning and the presence of flame. Notably, LFP cells themselves contain no chlorine (the electrolyte and active materials have fluorine and phosphorus, but not chlorine), so HCl emissions come from combustion of external materials (e.g., plastic casings, cable insulation, and fire suppressants). In the absence of direct large-scale burn test data, it is appropriate to use data for contaminants reported from the same study. Although HCl may not scale directly with cell capacity, the Project report included the raw data from Liu et al. (2021) and scaled it with capacity to create a relationship between the HCl data reported in Liu et al. (2021) and the equipment used in the Project modeling. Because the Liu et al. (2021) cells are smaller than the Project cells, the raw HCl emissions are increased from those reported in Liu et al. (2021). The upward scaling of raw HCl emissions represents a layer of conservatism incorporated into the February 2026 Plume Analysis.

Conversion from Liu Results to Project-Based Inputs

To convert the Liu et al. (2021) results to Project-based inputs, first, the Project identified HF and HCl values reported in Liu et al. (see Table 2).

Table 2. Converted Values

Gas	Liu et al. Reported Mass (grams per cell)*	Converted Mass (mg/cell)
HF	5.45 grams	5,450 mg
HCl	0.735 grams	735 mg

* Source: Liu et al. 2021
Notes: HF = hydrogen fluoride; HCl = hydrogen chloride; mg = milligrams

Next, an ampacity scaling factor was used to scale the values from Liu et al. (2021) to the Project, as follows:

- Study cell capacity (Liu et al. 2021): 243 Ah
- Project cell capacity: 314 Ah
- Scaling factor = 243 Ah/314 Ah = 0.77

That scaling factor was then applied to the mass of the Project cell (5.57 kilograms [kg]) to determine the study equivalent cell mass, because the study equivalent cell mass was not available:

- $5.57\text{ kg} \times 0.77 = 4.31\text{ kg}$ (study-equivalent mass)

The emission factors were then calculated by dividing the Liu et al. (2021) gas yields by the study-equivalent cell mass:

- HF emission factor = $5,450\text{ mg}/4.31\text{ kg} = 1,236.7\text{ mg/kg}$
- HCl emission factor = $735\text{ mg}/4.31\text{ kg} = 170.4\text{ mg/kg}$

The normalization factor from pouch to cylindrical of 0.5 was then applied to the HF emission factor as described in the February 2026 Plume Study. These mass-normalized emission factors (milligrams per kilogram [mg/kg] of cell mass) were then applied to the total modeled cell mass involved in the thermal runaway scenario to generate source emission rates for HF and HCl in the AERMOD dispersion model.

2.6 Request for Information 6

E-RFI-6. The emission rates for HF and HCl (shown above) used in the applicant's analysis seem to be much lower than values reported in other published literature, such as HF of 11,320 mg/kg and HCl of 2,575 mg/kg reported in "Ramboll 2024: Vistra Morro Bay Battery Energy Storage System (BESS) Project" (<https://neveragainmosslanding.org/wp-content/uploads/2025/04/Vistra-Morro-Bay-OCA-Ramboll-March-2024.pdf>). Please provide supporting documentation and justification demonstrating that the emission factors used are representative and conservative for modeling the project impacts during any BESS thermal runaway/fire event.

E-RFI-6. RESPONSE: The emission factors used in the February 2026 Plume Analysis were intended to represent a full containerized lithium iron phosphate (LFP) BESS fire on a battery-mass basis and to reflect flaming thermal runaway conditions. As explained more fully below, although the studies referenced in the Ramboll 2024 off-site consequence analysis noted in the CEC email data request provide important scientific context regarding lithium-ion battery failure behavior, their test scales, combustion conditions, and normalization methods are not suited for representing a full containerized LFP BESS fire in off-site plume modeling.

The Ramboll (2024)² off-site consequence analysis cites Larsson et al. (2014)³ for hydrogen fluoride (HF) emissions and Huang et al. (2021)⁴ for hydrogen chloride (HCl) emissions. The following is a discussion of the two studies as they pertain to the Project.

Larsson et al. (2014) evaluated HF emissions from lithium-ion battery fire tests conducted primarily on small-format cells and consumer-scale battery packs originally designed for laptops and plug-in hybrid electric vehicles. These test batteries differ substantially in size, construction, electrolyte inventory, and venting behavior from the large-format prismatic or cylindrical cells deployed in modern, utility-scale, containerized LFP BESS installations like the ones proposed for the Project. As a result, the physical fire dynamics and gas release mechanisms evaluated in Larsson et al. (2014) are not representative of contemporary BESS configurations.

Larsson et al. (2014) also reported HF yields using normalization approaches that are not readily scalable to or representative of full BESS container fire scenarios. In several tests, HF emissions were reported in units of milligrams per gram of mass lost rather than per unit of total battery mass. Because mass loss varies with test configuration, suppression effects, and venting behavior, this metric cannot be reliably extrapolated to a full containerized system. Although the study also presents HF yields normalized on an energy basis (mg/Wh), those values span nearly an order of magnitude, indicating that HF production is not linearly proportional to energy capacity. This wide variability underscores the uncertainty associated with extrapolating results from small-cell fire tests to large-scale BESS installations.

Importantly, Larsson et al. (2014) explicitly characterize their full-vehicle HF estimates as hypothetical extrapolations intended to illustrate potential hazards rather than to serve as predictive inputs for site-specific consequence modeling (Larsson et al. 2014, page 16). For the present analysis, the modeling objective was to minimize reliance on hypothetical extrapolation and instead use emission factors reported on a battery mass

⁴ Huang, Z., Xin Li, Qingshan Wang, Qiangling Duan, Yan Li, Lina Li, and Qingsong Wang. 2021. "Experimental Investigation on Thermal Runaway Propagation of Large Format Lithium-Ion Battery Modules with Two Cathodes." *International Journal of Heat and Mass Transfer* 172 (2021) 121077. <https://doi.org/10.1016/j.ijheatmasstransfer.2021.121077>.

basis derived from tests more closely aligned with flaming thermal runaway conditions relevant to containerized BESS fires. For these reasons, the emissions from Larsson et al. (2014) were determined to not be representative, and thus were not used as the primary source for HF emission inputs.

With respect to HCl emissions, Huang et al. (2021) investigated thermal runaway propagation in large-format lithium-ion battery modules containing both LFP and non-LFP chemistries. Although the study provides valuable insight into module-level behavior, the reported HCl emissions for LFP batteries were generated during non-flaming thermal runaway events. Complete thermal runaway occurred in only one of three LFP tests. HF was not detected, and 5.4 grams of HCl was detected in those tests. The absence of flaming combustion indicates that the chemical environment and temperature regime differed fundamentally from those expected in a fully developed containerized BESS fire.

The plume modeling conducted for this Project was intended to represent a conservative, full-container burn. Non-flaming thermal runaway tests do not capture the oxidative combustion chemistry, elevated flame temperatures, or polymer decomposition pathways that are present during a sustained BESS fire. As a result, direct application of the Huang et al. (2021) LFP results would not be representative of the Project's modeled scenario, and would not provide an appropriate basis for assessing potential off-site air quality impacts. However, Huang et al. (2021) do demonstrate that full thermal runaway and complete cell consumption is not inevitable, even under abusive conditions, which supports the case for conservatism in the modeling approach adopted in the February 2026 Plume Analysis.

In summary, although Larsson et al. (2014) and Huang et al. (2021) provide important scientific context regarding lithium-ion battery failure behavior, their test scales, combustion conditions, and normalization methods are not suited for representing a full containerized LFP BESS fire for off-site plume modeling.

Emission Factor Support

Due to the limitations described above, the HF and HCl emission factors used in the February 2026 Plume Analysis were derived from studies that explicitly evaluated flaming runaway conditions and reported emissions on a mass-normalized basis suitable for scaling to full BESS containers.

The HF and HCl emission factors used for the Project's BESS fire modeling were derived from Liu et al. (2021), a peer-reviewed study specifically examining gas releases under large-scale lithium-ion battery fire conditions. The Project's modeling used an HF emission factor of 631.86 mg/kg of battery and an HCl emission factor of 170.4 mg/kg of battery. These values are representative of the Project's large-scale LFP BESS fire scenario, and was conservative to ensure a health-protective assessment of potential impacts.

The emission factors from Liu et al. (2021) were identified as the most representative and appropriate for the Project's analyses because the experimental conditions closely replicate a full-scale, flaming BESS fire involving LFP chemistry. Liu et al. (2021) conducted controlled burn tests on large-format lithium-ion batteries and reported emission yields (including HF and HCl) on a mass-normalized basis (mg/kg of battery), which directly aligns with how the Project's dispersion model inputs are defined. Liu et al. (2021) also explicitly examined the influence of battery cathode chemistry on fire behavior and emissions, providing data relevant to LFP systems like the one proposed for the Project. By using LFP-specific data from Liu et al. (2021), the Project's analyses ensures that the modeling reflects the actual battery chemistry and potential failure mode of a containerized system. In contrast, other available studies either involve much smaller cells (necessitating uncertain extrapolations to a full BESS scale) or evaluate non-flaming thermal runaway scenarios that do not represent a

worst-case full fire. By basing the Project's analyses on Liu et al. (2021), the modeling captures the conditions of a fully developed, self-sustaining battery fire, which is the appropriate analog for a maximum, credible event in a large BESS enclosure.

The chosen HF emission factor is based on the quantitative HF yield reported by Liu et al. (2021) for LFP batteries under combustion conditions, with a 50% reduction applied to account for differences in cell format. The Project's BESS will use prismatic LFP cells, whereas many laboratory studies (including Liu et al.'s) often test pouch cells. Notably, research by Larsson et al. (2017)⁵ demonstrated that pouch cells tend to produce higher HF emissions than other cell form factors under similar conditions. The likely reason, as posited by Larsson et al. (2017), is that hard-cased cells (cylindrical or prismatic) can build up higher internal pressure before rupture, leading to a more forceful venting of gases and shorter duration of combustion. This rapid release can result in more incomplete combustion and, consequently, lower yields of HF and other combustion byproducts compared to pouch cells, which generally burn more gradually and completely. In Larsson et al.'s tests, for example, LFP pouch cells (20 Ah) at full charge produced on the order of 150–200 mg of HF per watt-hour (Wh) of battery capacity, whereas smaller, cylindrical LFP cells produced roughly 12–52 mg of HF per Wh. After converting to a mass basis, the cylindrical cells' HF emissions were approximately half (or even less) of the HF per-unit mass emitted by the larger pouch cells. In light of this evidence, the Project's modeling adjusted the raw HF emission factor from Liu et al. (2021) downward by a factor of 2. This yields 631.86 mg HF per kg of battery, which closely represents a severe fire involving cylindrical LFP cells.

The chosen HCl emission factor comes from the same Liu et al. (2021) source, which measured HCl in tandem with HF during large-scale battery fire tests. Using Liu et al.'s HCl data ensures internal consistency: the HF and HCl values stem from the same experimental conditions (same battery type, fire scenario, and measurement methods). This is preferable to mixing data from different studies because HCl generation in lithium-ion battery fires can depend on test-specific factors, such as the amount of plastic or PVC components burning and the presence of flame. Notably, LFP cells themselves contain no chlorine (the electrolyte and active materials have fluorine and phosphorus, but not chlorine), so HCl emissions come from combustion of external materials (e.g., plastic casings, cable insulation, or fire suppressants). The Liu et al. (2021) study's HCl yield of approximately 170 mg/kg can thus be viewed as a reasonable estimate for a scenario in which a BESS container fire burns not only the batteries, but also associated plastic materials. This value is of the same order or higher than HCl yields seen in other LFP-focused studies. For example, Huang et al. (2021) observed roughly 5.4 g of HCl from an 8.5 kg LFP module fire, equivalent to approximately 635 mg/kg. However, that was in a limited-scale test; in two other LFP trials without full flaming, HCl releases were negligible. Real BESS fires may vary, but the calculated value of 170.4 mg/kg HCl encompasses a scenario where some plastics burn.

The Project's approach was deliberately conservative at multiple levels. First, the use of mass-based emission factors from a fully involved fire study (Liu et al. 2021) inherently assumes a high degree of combustion of the BESS's battery mass, converting a significant fraction of the batteries' fluorine and chlorine-containing components into HF and HCl. The Project's model further assumes the complete combustion of an entire BESS enclosure's battery inventory over a 28-hour period—effectively a “worst-case” total-release scenario. These modeling parameters likely overstate the potential emissions for several reasons: (1) LFP batteries are relatively resistant to propagation of thermal runaway and may not burn completely in real incidents, whereas the Project's model assumed 100% consumption; (2) safety systems (e.g., fire suppression, venting) would limit

⁵ Larsson, Fredrik, Petra Andersson, Per Blomqvist, and Bengt-Erik Mellander. 2017. “Toxic Fluoride Gas Emissions from Lithium-Ion Battery Fires.” *Scientific Reports* Vol. 7, Article number: 10018 (2017). <https://www.nature.com/articles/s41598-017-09784-z#citeas>.

the extent and rate of hazardous gas production, yet the Project's modeling conservatively assumes all such systems fail and do not mitigate the fire; and (3) the Project's plume model does not account for the loss of HF through adsorption or deposition, which would result in lower emissions.

The numeric values of the emission factors were chosen to be on the high end of credible data for LFP. The HF factor of 631.86 mg/kg, even after the pouch-to-cylindrical adjustment, is high relative to most experimental LFP fire results (for instance, it is several times higher than the HF yield measured in full-scale LFP module tests without flame ignition). It is true that much higher HF figures can be found in literature for vastly different battery types or test conditions; for example, Larsson et al. (2014) reported up to approximately 200 mg/Wh of HF for certain small, high-cobalt cells, which would translate to tens of thousands of mg/kg for a large battery pack, and their extrapolation for an electric-vehicle fire suggested that more than 1 kg of HF could be released. However, those extreme values came from scenarios not analogous to the Project (different chemistries, much smaller cells, and intentionally exaggerated conditions), and were presented as hypothetical upper bounds rather than expected outcomes. Using such values for an LFP BESS would greatly over-predict emissions beyond any credible level. In fact, Ramboll (2024) noted that taking the absolute maximum HF/HCl emission factors from disparate studies "over-predicts the emissions likely to occur at BESS facilities, particularly those that employ LFP batteries." By using the Liu et al. (2021) data, which is specific to conditions similar to a BESS fire, and then conservatively adjusting the HF value to ensure relevance to the Project's prismatic cell design, the Project's modeling achieves a balance of realism and conservatism. The Project's HF and HCl inputs are high enough to cover severe failure conditions (full thermal runaway propagation with fire, all batteries involved), yet they avoid unsubstantiated extreme values from dissimilar battery types.

The emission factors of 631.86 mg/kg for HF and 170.4 mg/kg for HCl used in the Project's BESS fire impact modeling are grounded in a relevant large-scale experimental study (Liu et al. 2021) that were adjusted using peer-reviewed findings (Larsson et al. 2014) to reflect the specific characteristics of the Project's LFP prismatic cells. This ensures the factors are representative of the actual technology and potential fire conditions. At the same time, these values are intentionally conservative, chosen near the upper end of realistic emissions for LFP batteries and applied in conjunction with worst-case assumptions (complete container burn, no mitigation) so that the modeled off-site impacts overestimate the potential emissions and concentrations. By relying on robust scientific data and incorporating proven scaling adjustments, the Project's modeling provides confidence that the calculated emission factors provide a human health and environment-protective representation of a worst-case BESS thermal runaway/fire event. This approach is consistent with the CEC's guidance to use technically sound, peer-reviewed data, and to err on the side of over-predicting potential impacts rather than under-predicting them.

2.7 Request for Information 7

E-RFI-7. In Attachment A, Table 4 AERMOD Maximum Impact X/Q, the reported MEIR values are 872.12 for 1-hour and 661.22 for 8-hour. However, the AERMOD plot files provided are not consistent with these values. 01H1GALL.PLT indicates a maximum impact of 110.98 and 08H1GALL.PLT indicates a maximum impact of 18.49. Both are lower than the values in Table 4. Please clarify the discrepancy between the values reported in Table 4 and those shown in the provided PLT files. Please confirm whether the values in Table 4 are correct. If the values in Table 4 are correct, please provide the corresponding PLT files.

E-RFI-7. RESPONSE: The MEIR used in the February 2026 Plume Analysis is at 394942.29 meters east, 3816484.92 meters north and represents the highest potentially impacted residential structure; it is presented

in the model files labeled “Prairie Song Plume Study – Unit”. The values referenced are from the February 2026 Plume Analysis unit model run, and are shown in Exhibits 2 and 3, below. These can be found in the .AD subfolder in the associated AERMOD run folder, as well as on pages 949 and 1,834 of Data Request Response No. 5, Attachment B of Attachment 1 (Prairie Song BESS Project Plume Study – 2.19.26) to TN: 268721.

2.8 Request for Information 8

E-RFI-8. The meteorological data the applicant used is from Palmdale (as per Table 2), not from the one closer to Acton (<https://www.pwsweather.com/station/pws/KCAACTON3>). Palmdale and the airport are located in a much wider flat area where the mountains are more distant than at the site. According to people who live near the site and in Acton, the “funnel action” of the canyon forces the winds to flow from the west (or SW as the wind rose shows) to east, and east to west as the prevailing directions. Please demonstrate how the meteorological data from Palmdale would be representative of the project site. If this influenced the AERMOD results, please redo the modeling analysis using the more appropriate meteorological data.

E-RFI-8. RESPONSE: Meteorological datasets used for regulatory modeling must meet U.S. Environmental Protection Agency (EPA) guidance for data completeness, quality, and other regulatory requirements. The Palmdale Airport meteorological monitoring data managed and curated by the South Coast Air Quality Management District (AQMD) meets these important regulatory requirements, and is thus representative of and the most appropriate meteorological data for the Project’s analysis. In contrast, the Acton data does not satisfy the regulatory requirements for use in EPA’s AERMOD model.

Meteorological data used in regulatory AERMOD applications must comply with the EPA’s Guideline on Air Quality Models (Appendix W to 40 CFR Part 51), as revised in 2024, which designates AERMOD as the EPA preferred nearfield dispersion model. The Guideline on Air Quality Models specifies that meteorological inputs must be prepared using EPA-approved preprocessing methods, and use the latest version of the AERMOD Implementation Guide (2024 is the latest). Appendix W requires that meteorological data be representative of

conditions affecting the source and receptors, and that model inputs be developed in a manner consistent with EPA guidance to ensure technical defensibility in regulatory decision making.

As detailed in the AERMOD Implementation Guide,⁶ meteorological inputs must be processed using AERMET, the EPA-approved meteorological preprocessor. AERMET organizes raw meteorological observations and computes the boundary layer parameters required by AERMOD. The output consists of two required files: a surface file (.sfc) containing hourly surface and boundary layer parameters, such as wind speed and direction, friction velocity, Monin Obukhov length, and mixing height, and a profile file (.pfl) containing vertical profiles of wind speed, wind direction, temperature, and turbulence parameters. Both files are required for all regulatory AERMOD runs, and must be generated in the fixed-format structure expected by the model.

EPA guidance allows several types of meteorological data sources for use in AERMET, provided they are appropriately processed and quality assured. These sources include National Weather Service or Automated Surface Observing System (ASOS) surface observations, upper air soundings (typically twice daily radiosondes), site-specific on-site meteorological measurements, and prognostic meteorological model data, such as WRF. Regardless of the source, the data must demonstrate that it is representative of the modeling domain.

A critical component of AERMET processing is the specification of surface characteristics, including surface roughness length, albedo, and Bowen ratio. These parameters influence turbulence and atmospheric stability calculations, and must be developed using land-use-based methods that are spatially representative of the modeling area. EPA recommends the use of AERSURFACE to derive sector weighted surface characteristics, consistent with the AERMET algorithms. Use of default or generic values without justification is discouraged for regulatory applications, particularly in complex or heterogeneous land use settings.⁶

Meteorological datasets used for regulatory modeling must meet data completeness and quality requirements. EPA guidance generally recommends using at least one full year of representative data, with multiple years commonly applied for Prevention of Significant Deterioration and long-term impact assessments. Years with excessive missing or invalid data should be excluded. During processing, AERMET applies quality assurance checks and enforces a minimum wind speed threshold, below which hours are classified as calm. These calm hours are retained in the dataset as wind speed set to zero and wind direction undefined, preserving hourly continuity and ensuring conservative dispersion behavior in AERMOD.

The two closest meteorological monitoring stations to the Project site that meet the regulatory requirements stated above are the Palmdale Airport meteorological monitoring station (10.4 miles northeast of the Project site) and the Santa Clarita station (24.1 miles southwest of the Project site). The California Air Resources Board manages the Palmdale Airport meteorological monitoring station, and the South Coast AQMD manages the Santa Clarita station. The Antelope Valley AQMD does not maintain or provide AERMOD-ready meteorological data.

Notably, neither the EPA's Guideline on Air Quality Models nor its AERMOD Implementation Guide requires use of data from the closest meteorological station, particularly where such data does not meet completeness or quality requirements. The use of a station with regulatory-grade representative data is standard practice, compared to using closer, non-compliant data that could underestimate or mischaracterize dispersion conditions.

⁶ EPA (U.S. Environmental Protection Agency). 2024. *AERMOD Implementation Guide*. November 2024. https://gaftp.epa.gov/aqmg/SCRAM/models/preferred/aermod/aermod_implementation_guide.pdf.

The Santa Clarita station meteorological data was processed for use in AERMOD by the South Coast AQMD. The meteorological data was processed with EPA's AERMET Version 22112. Raw meteorological data from South Coast AQMD's monitoring stations and the ASOS stations within South Coast AQMD's jurisdiction were collected for 2010 through 2023. Hourly wind and temperature data were collected from both South Coast AQMD and ASOS stations, but cloud cover and 1-minute wind data were only available from the ASOS stations. The ASOS 1-minute wind data was processed with EPA's processor AERMINUTE Version 15272 and included in AERMET for ASOS stations with the use of a wind speed threshold of 0.5 meters per second (m/s), which is consistent with EPA guidelines. Upper air data from the Miramar (NKX) station was used for the upper air data input to AERMET. The ADJ_U* option was enabled in the calculations.

Surface characteristics, such as albedo, Bowen ratio, and surface roughness, were determined from EPA's processor AERSURFACE, Version 20060. Each station's Bowen ratio varies by year based on the year's precipitation total compared to the 30-year climatological average precipitation. This comparison results in a year being classified as average, dry, or wet. Data from the U.S. Geological Survey's 2016 National Land Cover Database (NLCD), including land cover, tree canopy, and impervious cover, was used as the land cover input into AERSURFACE, and arid region was set to "Yes". Twelve equal wind direction sectors were used, and the sectors with airports were labeled in the input into AERSURFACE. The ZORAD option was used for the calculations.

After the meteorological data was processed with AERMET, the data went through quality control. An hour was deemed complete only if temperature, wind speed, wind direction, and cloud cover data were all concurrently available. Data in a given calendar year did not pass quality control if more than 10% of measured parameters were missing in any quarter, or more than 10% of hours had calm winds in any quarter. Additional checks determined that there were no step changes in measured parameters, that wind roses were consistent with the terrain, that seasonal and diurnal variations were reasonable, and that wind speeds were reasonable. The most recent 5 years of data meeting the quality control criteria were then identified for each station, with some stations being eliminated for use in dispersion modeling applications.

The Palmdale Airport meteorological monitoring station data was processed by the California Air Resources Board using AERMET, Versions 19191 and 21112. To create those files, the following data were required as inputs into AERMET: surface meteorological data, upper air meteorological data, and land use data.

Raw hourly surface meteorological data was obtained from the National Oceanic and Atmospheric Administration (NOAA) National Climatic Data Center for 2010 through 2021. For those years, the most recent and complete 5 years of meteorological data were processed. More information regarding this requirement can be found in Appendix W of EPA's Guideline on Air Quality Models (40 CFR Part 51), and OEHHA's Air Toxics Hot Spots Program Guidance Manual for Preparation of Health Risk Assessments.⁷ Where data was available from ASOS stations, the meteorological preprocessor, known as AERMINUTE, was used to process ASOS 1-minute wind data. The California Air Resources Board used a minimum wind speed threshold of 0.5 m/s, which is consistent with EPA guidance. Wind speeds below this threshold were treated as calm.

Raw upper air data was obtained from NOAA's Earth System Research Laboratory (ESRL) for 2010 through 2021. In AERMOD, the surface station's nearest upper air station was used, except for stations in the Mojave

⁷ OEHHA (Office of Environmental Health Hazard Assessment). 2015. *Air Toxics Hot Spots Program Risk Assessment Guidelines, Guidance Manual for Preparation of Health Risk Assessments*. February 2015. <https://oehha.ca.gov/sites/default/files/media/downloads/crn/2015guidancemanual.pdf>.

Desert AQMD. For surface stations in the Mojave Desert AQMD, the most representative upper air station was used in AERMOD.

The preprocessor AERSURFACE, Version 20060, was used to determine land-use characteristics and to determine albedo, Bowen ratio, and surface roughness values. The U.S. Geological Survey's 2016 National Land Cover Database (NLCD) was used for the land-use data input into AERSURFACE. Albedo and surface roughness length values can be determined directly from this land-use data. Bowen ratio is an indicator of surface moisture, and its value varies from year to year based on land-use type combined with annual precipitation totals compared to the 30-year climatological average precipitation. The meteorological data files were processed both with and without the ADJ U* option.

The referenced station in Acton does not produce data that meets the regulatory requirements, as discussed above. Therefore, it is not appropriate to use as a source for modeling purposes. Both the Palmdale Airport and Santa Clarita meteorological monitoring stations were used in the initial model runs (to test conservatism). The Palmdale Airport meteorological data resulted in a higher concentration at the MEIR compared to the Santa Clarita station. Thus, although both the Palmdale Airport and the Santa Clarita meteorological monitoring stations satisfy all applicable EPA guidance and regulatory requirements, the Project's analysis used the Palmdale Airport meteorological data, which conservatively overpredicted potential impacts compared to the similarly qualified Santa Clarita station dataset. Further, the average wind speed from the Palmdale Airport meteorological monitoring station is 4.81 meters per second (10.76 miles per hour) compared to the average wind speed of the nearest weather station to the Project site in Acton of 3.17 meters per second (7.1 miles per hour). Therefore, the data from the Palmdale Airport meteorological monitoring station is conservatively representative of the modeling domain.

With regards to the prevailing wind direction of each meteorological station, the wind is predominantly blowing from the southwest at the Palmdale Airport meteorological monitoring station and from the southeast at the Santa Clarita meteorological monitoring station. The closest weather station to the Project site in Acton shows wind predominantly blowing from the northeast. Although the prevailing wind direction at the Palmdale Airport and Santa Clarita meteorological monitoring stations do not reflect those shown at the Acton weather station, wind direction is not the only factor that defines whether a meteorological dataset is representative or not. As discussed above, the meteorological data includes upper air data, albedo, Bowen ratio, and surface roughness. These other factors within the Palmdale Airport and Santa Clarita datasets are similar to those found at the Project site due to proximity, which makes the data conservatively representative and appropriate for use. Further, although AERMOD does have the wind rotation option, which allows for rotation of the meteorological wind direction relative to the site, the EPA's AERMOD user's guide explicitly says it "should be used only with extreme caution and clear justification."⁸ It is not appropriate to rotate either regulatory-approved meteorological dataset because there are no known (or documented) calibration errors.⁶

Absent an on-site or regulatory-approved meteorological dataset in Acton, the Palmdale Airport and Santa Clarita datasets are most appropriate for use in modeling emissions at the Project site. As previously indicated, the most conservative of the two datasets that met modeling requirements was selected based on initial testing. This is appropriate because there are receptors on the northern and southern boundaries of the Project site. Therefore, locating the BESS container in the most northeastern corner closest to a sensitive receptor using the Palmdale Airport meteorological monitoring data represents the most conservative modeling scenario.

⁸ EPA. 2024. *User's Guide for the AMS/EPA Regulatory Model (AERMOD)*. November 2024. https://gaftp.epa.gov/aqmg/SCRAM/models/preferred/aermod/aermod_userguide.pdf.

Attachment A

Plume Study – Redline Version

MEMORANDUM

To: California Energy Commission
From: Prairie Song Reliability Project LLC
Subject: Plume Study for the Prairie Song Reliability Project
Date: ~~March 18, 2026~~ March 19, 2026
Attachments: A, Emission Calculations
B, Dispersion Modeling Outputs

On January 30, 2026, the Executive Director of the California Energy Commission (CEC) issued a Determination of Complete Application for the Prairie Song Reliability Project (Project). CEC Staff also issued requests for information to further assist CEC Staff in the preparation of a Staff Assessment for the Project.

Information request REV 2 DR PH-2 requested additional analysis of potential worst-case impacts in the event of a potential battery energy storage system (BESS) thermal runaway/fire event. This memorandum provides a supplemental thermal runaway/fire scenario¹ analysis technical memorandum (plume study) for the Project in response to Information request REV 2 DR PH-2. This analysis is in addition to the previously docketed Plume Analysis prepared by Fire & Risk Alliance (TN:264382; Appendix 3.17D) and provides a complementary analysis of fire safety and public health. The contents and organization of this memorandum are as follows: Executive Summary, Project Description, Codes and Standards, Neighboring Uses, General Analysis and Methodology, Significance Criteria, Results, Conclusions, and References Cited.

1 Executive Summary

The Project would involve constructing and operating a BESS within unincorporated Los Angeles County (County), California. This plume study evaluated the Project's potential to cause adverse health effects on nearby receptors in the highly unlikely scenario of a thermal runaway event at the BESS.

This plume study provides a list of the chemical constituents that could be emitted from lithium-iron phosphate (LFP) batteries during a thermal runaway event, based on the Underwriters Laboratories ("UL") 9540A testing, the large-scale burn test (LSBT) report, and a literature review.

The Sungrow PowerTitan 2.0 has been selected for this Project application as a representative system. The UL9540A unit tests for PowerTitan 2.0 showed that three (3) initiating cells went into thermal runaway and

¹ Thermal runaway is a situation where the current flowing through the battery cell during either operation or a short circuit causes the cell temperature to rise to the point where a feedback loop can cause a thermal chain reaction.

propagated to two (2) adjacent cells, for a total of five (5) cells. The LSBT showed that after two (2) heaters forced cells into thermal runaway and sparking devices were used to ignite a fire, the fire slowed down and stopped, even in the absence of all other safety features being disabled. Additional heaters needed to be turned on and kept on to force the full unit to a burn. Therefore, this analysis conservatively assumes an entire unit would be affected (i.e., 4,992 cells), even though the LSBT showed that multiple failures and additional actions by the testers to force a full unit burn were necessary, and therefore presents a very conservative scenario that satisfies the information request for a worst-case analysis.

The potential impacts of toxic air contaminants (TACs) from a thermal runaway event were evaluated using dispersion modeling to calculate offsite concentrations of TACs. The concentrations were then compared to the Office of Environmental Health Hazard Assessment (OEHHA) acute reference exposure levels (RELs), level 1 U.S. Environmental Protection Agency (EPA) Acute Exposure Guideline Levels (AEGLs) if no REL exists, the OEHHA threshold of 1 for the acute hazard quotient, and any ambient air quality standards (AAQS), as applicable. As further discussed herein, emissions calculations indicated that the public health impacts from TACs associated with the worst-case battery cell malfunction scenario were less than significant from a public health perspective.

2 Project Description

The Project would include a 1,150-Megawatt (MW) utility-scale BESS installation designed to support grid reliability, renewable energy integration, and local energy resilience. The primary components of the Project include a containerized BESS facility, operations and maintenance (O&M) buildings, an on-site Project substation, a 500-kilovolt (kV) overhead generation interconnection (gen-tie) transmission line, and interconnection facilities within the existing Southern California Edison (SCE)-owned and operated Vincent Substation.

Electrical energy will be transferred from the existing power grid to the Project for storage and from the Project to the power grid when additional electricity is needed. The Project will provide additional capacity to the electrical grid to assist with serving load during periods of peak demand by charging when demand is low and discharging when demand is high. This operating principle increases the integration of additional intermittent renewable energy, such as wind and solar, in California's energy mix and reduces the need to operate natural gas power plants. The Project will also serve as an additional local/regional capacity resource that will enhance grid reliability, particularly to the Los Angeles Basin local reliability area and may allow for the deferral or avoidance of regional transmission facilities.

The Project will be remotely operated and monitored year-round as well as supported by on-site O&M staff seven (7) days a week. The Project will be available to receive or deliver energy 24 hours a day and 365 days a year. During the operational life of the Project, qualified technicians will inspect the Project facilities and conduct necessary maintenance to ensure reliable and safe operational readiness.

2.1 Battery Technology Overview

The energy storage facility will utilize a modular and containerized BESS. There are several battery cell technologies commercially available, with one of the most common presently being LFP cells, or similar. LFP technology is considered one of the safest, most efficient, and thus commercially financeable energy storage technologies available on the market. The initial Project concept has been developed assuming an LFP technology.

LFP batteries are a type of rechargeable lithium-ion battery that uses iron phosphate as the cathode material and a graphitic carbon electrode with a metallic backing as the anode. They offer several advantages, including a longer lifespan, higher safety, and better discharge capacity compared to traditional lithium-ion batteries. LFP batteries also have a lower environmental impact due to the use of more abundant and less toxic materials like iron and phosphorus.

The Sungrow PowerTitan 2.0 has been selected for this Plume Study as a representative system. The Sungrow PowerTitan 2.0 battery energy storage units are a liquid-cooled system engineered for high safety, efficiency, and rapid deployment. Each PowerTitan 2.0 unit integrates battery modules, Power Conversion Systems (PCS), HVAC, fire suppression systems, and Battery Energy Management System (BEMS) into a pre-assembled, containerized format. The PowerTitan 2.0 container enclosure protects the batteries from mechanical damage and weather conditions and provides a rigid metal frame to house six (6) racks of eight (8) modules, with each module containing 104 cells. This plug-and-play architecture reduces on-site installation time by up to 80% compared to conventional systems and minimizes the need for field wiring or battery handling (Sungrow 2024).

The PowerTitan 2.0 employs LFP battery chemistry, chosen for its superior thermal stability and resistance to thermal runaway. The olivine crystal structure of LFP provides strong covalent bonding between iron and phosphate ions, which stabilizes the cathode and prevents oxygen release during thermal decomposition, significantly reducing the risk of combustion (Jie 2024). The system's liquid cooling technology maintains optimal cell temperatures across a wide range of environmental conditions, from -30°C to +55°C, and supports high-density deployments without compromising safety. Each unit is National Fire Protection Association (NFPA) compliant, UL9540A-tested, and includes multi-level protection features such as gas detection, thermal sensors, and automatic fire suppression systems (Sungrow 2024).

Recent research into thermal runaway behavior confirms the advantages of LFP chemistry in large-scale applications. Compared to nickel manganese cobalt (NMC)-based systems, LFP batteries exhibit higher thermal runaway onset temperatures, lower peak heat release rates, and slower propagation between cells. The structural stability of LFP translates into a thermal runaway threshold that is typically above 270°C compared to around 150–200°C for NMC. The electrochemical potential of LFP is lower than that of NMC, resulting in a lower nominal cell voltage (approximately 3.2 V versus 3.6–3.7 V for NMC) and consequently lower energy density. LFP cells exhibit superior cycle life, often exceeding 4,000 cycles at 80% depth of discharge, and maintain performance across a wider range of temperatures. LFP cells are also less prone to capacity fade, which not only improves energy performance but also reduces thermal stress on the batteries (Preger et al. 2020). From a safety engineering perspective, the differences in thermal behavior are critical. NMC cells require more aggressive thermal management and are more likely to propagate failure across adjacent cells if a single cell enters thermal runaway. LFP cells, by contrast, tend to fail passively and are less likely to ignite or propagate heat to neighboring cells. This makes LFP a preferred chemistry for stationary applications where safety, longevity, and cost stability are prioritized over compactness. In experimental scenarios involving coupled abuse conditions such as heating combined with overcharge or external short circuit, LFP cells demonstrated delayed ignition, reduced flame height, and lower total heat release. These characteristics are critical in preventing cascading failures in densely packed installations.

The Project's design reflects these safety priorities. The PowerTitan 2.0 units are deployed in rows with physical separation, allowing for effective containment of any thermal event. The system's integrated monitoring and control platform enables real-time diagnostics, predictive maintenance, and remote shutdown capabilities. This level of visibility and control is essential for managing risk and ensuring compliance with California's evolving BESS safety regulations.

The United States' (US) installations of advanced energy storage — almost entirely lithium-ion battery systems — surpassed 3 gigawatt (GW) in the second quarter of 2024 according to research firm Wood Mackenzie Power & Renewables, which forecasts, then records and analyses energy storage deployments (Utility Dive News 2024). California had approximately 13,000 GW of utility scale battery storage installed as of 2024 and is projected to reach 54,000 GW by 2045.

3 Codes and Standards

3.1 Battery Testing Requirements and Regulations

BESS facilities and batteries are subject to several strict safety codes and standards. Some of the relevant codes and standards are discussed below.

Underwriters Laboratories (UL), a globally recognized safety certification company.

UL9540A: Test Method for Evaluating Thermal Runaway Fire Propagation in Battery Energy Storage Systems – this test methodology evaluates the fire characteristics of battery cells, modules, and installations that are purposefully induced into thermal runaway. The data generated can be used to determine the fire and explosion protection required for installation of a BESS.

UL1973: Standard for Batteries for Use in Stationary, Vehicle Auxiliary Power and Light Electric Rail (LER) Applications - This standard evaluates the battery system's ability to safely withstand simulated abuse conditions. This standard evaluates the system based upon the manufacturer's specified charge and discharge parameters. It requires that a BESS is not allowed to be an explosion hazard when exposed to an external fire source and that a single cell failure will not result in a cascading thermal runaway of cells.

UL1741: Inverters, Controllers, Converters, and Interconnection Equipment Standards - These requirements cover inverters, converters, charge controllers, and interconnection system equipment (ISE) intended for use in stand-alone (not grid-connected) or interactive (grid-connected) power systems. Interactive inverters, converters, and ISE are intended to be operated in parallel with an electric power system (EPS) to supply power to common loads.

UL9540: Energy Storage Systems and Equipment – This standard requires compliance with key UL sub-standards as well as standards from other recognized parties to certify safety of an integrated energy storage system.

International Fire Code (IFC): IFC is the model up-to-date fire code addressing conditions hazardous to life and property from fire, explosion, handling or use of hazardous materials and the use and occupancy of buildings and premises.

IFC specifies minimum size requiring permits (Lithium, all types, 20 kilowatt-hours (kWh)), specifies maximum limits on sizing for battery systems (Lithium all type, 50 kwh each array), seismic and structural design, spacing (minimum 3 feet separation of arrays), vehicle impact protection, testing, maintenance and repairs, maximum quantities within a building (Lithium of 600 kwh), battery management system (BMS)

monitoring, shutdown and notification requirements, automatic smoke detector requirements, automatic fire sprinkler systems, and ventilation specifications.

California Fire Code (CFC): The CFC is promulgated in the California Code of Regulations Title 24, Part 9, and contains regulations consistent with nationally recognized and accepted practices for safeguarding life and property from the following hazards:

- Fire and explosion
- Dangerous conditions arising from the storage, handling, and use of hazardous materials and devices
- Hazardous conditions in the use or occupancy of buildings or premises

The CFC also contains provisions to assist emergency response personnel. The CFC is a fully integrated code based on the IFC, described previously.

CFC Chapter 12 (Energy Systems): Chapter 12 was added to the CFC to address standby and emergency power, portable generators, photovoltaic systems, fuel cell energy systems, and energy storage systems. From CFC Chapter 12, a BESS must meet the provisions and requirements of Sections 1201 (General) and 1207 (Electrical Energy Storage Systems).

Institute of Electrical and Electronics Engineers (IEEE): The world's largest technical professional organization dedicated to advancing technology.

IEEE C2: This Code covers basic provisions for safeguarding of persons from hazards arising from the installation, operation, or maintenance of (1) conductors and equipment in electric supply stations, and (2) overhead and underground electric supply and communication lines. It also includes work rules for the construction, maintenance, and operation of electric supply and communication lines and equipment. The Code is applicable to the systems and equipment operated by utilities, or similar systems and equipment, of an industrial establishment or complex under the control of qualified persons.

National Fire Protection Association (NFPA): NFPA is an international nonprofit that develops standards to minimize risks and losses from fire, electrical hazards, and other dangers.

NFPA 70: National Electrical Code, addresses electrical design, installation, and inspection.

NFPA 550: Guide to Fire Safety Concepts Tree for Protecting Energy Systems - addresses issues such as utilizing BMS and compatible equipment, ventilation as needed, fire resistive separation, array spacing, and signage.

NFPA 855: Standard for the Installation of Stationary Energy Storage Systems - offers comprehensive criteria for the fire protection of BESS installations based on the technology used in BESS, the setting where the technology is being installed, the size and separation of BESS installations, and the fire suppression and control systems in place. Additional considerations include ventilation, detection, signage, listings, and emergency operations responding to BESS emergencies.

California Public Utilities Commission (CPUC): CPUC is a regulatory agency responsible for overseeing utility services and infrastructure in California, including electricity, natural gas, telecommunications, water, and transportation.

Its mission is to ensure that Californians receive safe, reliable, and affordable utility services. The CPUC sets standards, conducts inspections, and enforces regulations to maintain service quality and public safety. It also addresses consumer complaints, offers financial assistance programs, and promotes clean energy initiatives.

CPUC General Order 167-C: Operational standards and maintenance protocols for electric generation facilities and energy storage systems in California. It emphasizes the importance of reliability and safety, detailing requirements for regular inspections, performance monitoring, and reporting. The order mandates that facilities adhere to specific guidelines to ensure consistent operation and prevent outages, with a focus on maintaining equipment and infrastructure. Compliance is enforced through periodic audits and penalties for non-compliance, aiming to uphold high standards in the state's energy sector.

4 Neighboring Uses

Some land uses are considered more sensitive to changes in air quality than others, depending on the population groups and the activities involved. People most likely to be affected by air pollution include children, the elderly, athletes, and people with cardiovascular and chronic respiratory diseases. Facilities and structures where these air-pollution-sensitive people live or spend considerable amounts of time are known as “sensitive receptors.” Land uses where air-pollution-sensitive individuals are most likely to spend time include schools and schoolyards, parks and playgrounds, daycare centers, nursing homes, hospitals, and residential communities (sensitive sites or sensitive land uses) (CARB 2005). The Antelope Valley Air Quality Management District (AVAQMD) identifies residences, daycare centers, playgrounds, and medical facilities as sensitive receptors for the purposes of identifying air quality impacts (AVAQMD 2016).

The closest sensitive receptors to the Project site are residences located immediately adjacent to the west (along Malinta Avenue), north (along Tortuga Street and Soledad Canyon Road), and south (across Soledad Canyon Road) of the BESS facility Project site boundary. The nearest school is the Meadowlark Elementary School, located approximately two (2) miles to the west of the proposed BESS facility. This analysis also assesses impacts to non-sensitive receptor commercial uses, with the nearest being approximately 815 feet to the north of the Project. The location of the neighboring uses by type are shown in Figure 1.

5 General Analysis and Methodology

As described previously in Section 3, Codes and Standards, based on the requirements in Chapter 12 of the California Fire Code and the NFPA 855 standard, the risk of fire, explosion, and toxic release are minimized by the installation of energy management systems, fire detection and protection systems, explosion control systems, and ventilation. Further protection to the surrounding properties can be provided through proper pre-planning and coordination with local emergency agencies. Pre-planning for BESS facilities can be accomplished through the preparation of a Hazard Mitigation Analysis, which is used to evaluate the consequences associated with a potential project system failure and how those potential failures meet local codes and standards, in this case the Los Angeles County Fire Code. An additional pre-planning best practice is the preparation of an Emergency Response and Emergency Action Plan (ERP), which is required by Public Utilities Code Section 761.3. ERPs consider responses to potential offsite impacts, including poor air quality, and include procedures that provide for the safety of surrounding properties.

During normal operations, there will be no toxic air emissions from the Project. However, to evaluate potential worst-case public health impacts for this analysis, this report assumes the highly unlikely event of multiple safety and ventilation system failures so that a battery cell malfunction is not controlled. It is also assumed that the battery cell malfunction continues throughout the entire unit, consuming the totality of every cell until the reaction ceases. Based on the results of the UL9450A testing and the LSBT assumptions of multiple failures and additional actions by the testers required to force a full unit burn, the assumption that the totality of every cell is consumed is very conservative.

In the event of a battery cell malfunction, it is possible that a thermal runaway event and/or a fire could occur. While modern-day systems are designed to contain such fires within a single battery module or cabinet, if a fire does occur, some limited pollutants could be emitted to the atmosphere. Unlike other structural fires, the primary emissions from a thermal runaway event of a battery energy systems are flammable gases, which burn or dissipate within the vicinity of the battery unit. The majority of the battery structure is non-combustible.

To provide the worst-case scenario requested, it is assumed that the release of specific pollutants to the atmosphere would occur within a relatively short and concentrated period of time, based on the 1-hour exposure of TAC thresholds. The emissions modeled for a thermal runaway were based on the cell level UL9540A testing, the LSBT report, and applicable literature. Per the LSBT, emissions from a thermal runaway were observed for 28.03 hours for an entire unit, which were normalized to an hourly rate for the thermal runaway analysis (Sungrow 2025). Emission rates from the cell level UL9540A testing were extrapolated to an entire unit (4,992 cells). The actual rate of release would be dependent on energy stored within the individual battery system.

In the unlikely event of a battery cell malfunction, the primary emissions released would be carbon dioxide (CO₂), hydrogen (H₂), and carbon monoxide (CO), along with lesser amounts of other compounds. Table 1 provides a list of chemical constituents that could be emitted from LFP batteries during a thermal runaway event, based on the UL9540A testing, LSBT, and literature review.

Table 1. Potential Chemical Constituents Emitted from LFP Batteries

Pollutant	Chemical Formula	CAS Number	Measured Percent
UL9540A Testing			
Methane	CH ₄	74-82-8	6.421%
Acetylene	C ₂ H ₂	74-86-2	0.339%

Table 1. Potential Chemical Constituents Emitted from LFP Batteries

Pollutant	Chemical Formula	CAS Number	Measured Percent
Ethylene	C ₂ H ₄	74-85-1	3.827%
Ethane	C ₂ H ₆	74-84-0	0.996%

Pollutants emitted and % composition based on the Cell Test Report UL9540A, large scale burn test, and literature review.

The potential impacts of TACs from a thermal runaway event were evaluated using dispersion modeling to calculate offsite concentrations of TACs. The concentrations were then compared to the OEHHA acute RELs, AEGLs if no REL exists, and the OEHHA threshold of 1 for the acute hazard quotient, and any AAQS, as applicable. The methodology of each source of emission factors is discussed further in this section.

5.1 Thermal Runaway Emission Sources

5.1.1 UL9540A Testing

The UL9540A unit tests for the Sungrow PowerTitan 2.0 forced initiating cells into thermal runaway, through the addition of heat via glass fiber thermocouples. No external flaming or flame venting occurred during the UL9540A testing at the unit level. There are no single failures identified in the failure modes and effects analysis, documented in available BESS failure literature, or reported in anecdotal case reports that show or support a mechanism of failure that would cause thermal runaway to occur in all cells within a single module simultaneously, nor propagate to other modules in a rack. As such, there is no existing test data or established failure mechanism in the UL9540A reports that documented all 104 cells within a module or 4,992 cells within a BESS to undergo thermal runaway from a single failure. Rather, thermal runaway propagation from cell to cell would remain a direct component of battery gas release timing, release conditions, and associated consequences for all potential single failures initiating thermal runaway and battery gas venting in the PowerTitan 2.0 BESS. The UL9540A test was used as the basis for emissions of methane, acetylene, ethylene, ethane, propylene, propane, isobutane, trans butene, n-butene, pentane, isopentane, 2-methyl-1,3-butadiene, carbon monoxide, carbon dioxide, and hydrogen.

5.1.2 Large Scale Burn Test

A LSBT was conducted on the Sungrow PowerTitan 2.0 where an entire unit was forced into a thermal runaway (Sungrow 2025). The ambient conditions during the testing showed wind speed between 0 and 2.7 meters per second (m/s). The CSA TS-800 standard allows up to 2.7 m/s. The wind direction was predominantly blowing from the south, west, and then east towards the end of the test. The temperature ranged from 13 to 25°C during the test (CSA standard allows 10 to 40°C). The humidity varied from 45% to 87% (CSA standard allows below 90%). A continuous gas sampling system using a Raman spectrometer was used to analyze vent gases. The following gases were monitored during the test progression in a continuous manner: H₂, O₂, CO₂, CO, and HC and H₂S. In addition, 32 discrete gas samples were collected at 10 and 20 meters downwind into sample canisters to have gas analysis performed post-test to determine concentrations of gases present. Gas chromatography-mass spectrometry (GC-MS), thermal desorption gas chromatography with mass spectrometric detection (TDS-GCMS), ion chromatography (IC), and gas chromatography-flame ionization detection (GC-FID) were used to analyze the compositions and concentrations in volume. Electric thin-film heaters were used to induce the thermal runaway in one module and sparkers were used to ignite the gases. Even though all the safety mechanisms were turned off, the first fire slowed and stopped. Later in the test, additional heaters in the module were turned on to force the rest of the module into thermal runaway. Deflagration panels worked successfully and the fire in the container did not spread to any other container or damage the internal modules of any other containers. The LSBT was used as the basis for emissions of benzene, formaldehyde, toluene, sulfur dioxide, and nitrogen dioxide.

5.1.3 Literature Review

A literature review was conducted to identify other potential emissions from a LFP thermal runaway that were not identified in the UL9540A testing and LSBT. The literature review focused on studies that were representative of the chemistry (LFP) and cell type (cylindrical). It should be noted that there were no publicly available LSBT studies to review outside that of the Sungrow PowerTitan 2.0. The available studies were conducted at the cell level with much smaller capacity cells than the Project (3.2-20 ampere-hours compared to 314 ampere-hours). The literature review was used as the basis for emissions of hydrogen fluoride, hydrogen cyanide, and hydrochloric acid.

Hydrogen Fluoride (HF)

Larsson et al showed that when testing multiple LFP cells with different sizes and form factors, reported hydrogen fluoride (HF) results had an order-of-magnitude variability at similar capacities and the HF yield depends on venting dynamics, construction, and sampling method, not capacity (Larsson et al 2017). FTIR measurements represent HF that remains in the air and is relevant to inhalation exposure, whereas water-washing or impinger methods capture total fluorine, including fluorinated intermediates (e.g., POF_3) that hydrolyze to HF during sampling and would not remain fully airborne. This report explicitly acknowledges this distinction and adopts FTIR based yields for air dispersion modeling to avoid systematic overprediction of airborne HF. It was also observed that HF originates from fluorine-based materials, not stored energy. Therefore, the cell-level results do not scale proportionally with nominal capacity; rather, they scale with electrolyte mass, electrode surface area, and total materials mass. HF generated during lithium-ion battery fires is highly water soluble and reactive and is rapidly scavenged by fire suppression water, enclosure surfaces, and soot (EPA 1993). Experimental studies of battery fires and industrial HF releases show that only a fraction of generated HF remains airborne. Larsson et al also observed that there was a 75% reduction in HF emissions in cylindrical cells compared to pouch, due to increased mechanical confinement, restricted vent paths, and partial retention or internal recombination of fluorinated species. As the Sungrow PowerTitan 2.0 includes prismatic cells, a conservative reduction factor of 0.5 was applied to the HF emission rates (which were based on pouch cells) in the analysis. While HF was not evaluated in the UL9540A or LSBT, the emission factor of 1,264 milligrams per cubic meter was included herein as the analysis of a 243Ah pouch cell is the most representative of the Project's chemistry and configuration (Liu et al 2021).

Hydrogen Cyanide (HCN)

HCN is a recognized toxic byproduct of LFP thermal runaway, formed primarily from the thermal decomposition and combustion of nitrogen containing electrolytes, binders, and polymeric components within lithium-ion cells. Experimental studies and consequence modeling analyses show that during thermal runaway—especially when cell vent gases ignite or when plastics and electrolytes burn—HCN can be released (Kwon et al 2024). In laboratory thermal runaway tests, HCN emissions are limited in total mass and duration because they involve only single cells or small modules under controlled ventilation, making the results useful for identifying formation mechanisms but not for predicting real world exposure. Therefore, the application of laboratory testing is considered conservative. HCN emissions were modeled using average volumetric results from DNV GL 2019.

Hydrogen Chloride (HCl)

HCL emissions were modeled using an emission factor of 170 mg/kg, also expressed per unit mass of battery material (Liu et al 2021). HCl is consistently a minor constituent of LFP vent gas, with mass release rates substantially lower than HF and rarely controlling exposure distances in dispersion modeling. FTIR based measurements reported by Larsson et al. show limited HCl formation during LFP events, reflecting the absence of chlorine rich cathode materials and minimal contribution from enclosure materials under nonflaming conditions (Larsson et al., 2017).

Additional testing summarized by DNV GL 2019 confirms that elevated HCl concentrations are primarily associated with combustion of external chlorinated plastics rather than intrinsic battery materials, which is not assumed in the provided AERMOD analysis. The selected HCl value therefore represents the upper mid range of gas phase HCl reported for LFP cells and conservatively accounts for airborne irritant potential without assuming combustion of nonbattery materials.

Acrolein

Two studies detected acrolein from lithium ion fire cell releases, Long et al., 2013 and Nedjalkov et al., 2016. Long et al studied burns for electric vehicles (EV) of unknown chemistry. The analysis consisted of full-scale fire testing on a battery pack and an EV. Acrolein was detected, but measurements were not recorded. Due to uncertainty on battery type, a lack of applicability between a BESS container and an EV, and a lack of reported numbers, data from the Long study cannot be applied to this analysis. Nedjalkov studied NMC cells only. Our literature review did not reveal any studies showing acrolein production during an LFP thermal event, as such acrolein was not included in the plume analysis.

Carbonyl Fluoride (COF₂)

Our literature review could not find any studies that measured COF₂ production in an LFP thermal event that would be usable for modeling purposes. The absence of COF₂ in LFP thermal runaway experiments is chemically consistent. COF₂ is highly reactive and hydrolyzes rapidly to HF and CO₂ in the presence of moisture (Bugrynec et al 2024). Battery fire environments contain water vapor, combustion radicals, and hot surfaces, all of which favor rapid destruction of COF₂. LFP batteries generally do not contain fluorinated cathode materials, limiting fluorine availability to electrolyte components, which preferentially form HF. As a result, even if COF₂ were transiently formed at the molecular scale, it would not persist as a measurable airborne toxicant, and therefore was not included in our plume study.

Particulate Matter (PM)

The particulate matter (PM) emission rates reported in Claassen 2024 are not representative of a full BESS thermal runaway event because the experiments were conducted on individual LFP and lithium-cobalt oxide cells rather than multicell modules or racks, which means the experiments lack the complex thermal propagation behavior, cascading failures, and cumulative energy release that occur in real BESS incidents. The cells were externally heated on a hot plate rather than failing from realistic mechanisms such as internal shorts, propagation, or overcharge, which strongly influences the type and quantity of emitted particles. The tests occurred inside an open, ventilated burn chamber, without the confinement, restricted airflow, gas buildup, enclosure heating, and secondary combustion typical of BESS cabinets, all of which significantly alter aerosol formation and PM concentrations. For these reasons, while the study provides valuable insights into cell level particle emissions, the measured PM rates cannot be applied to a container level BESS thermal runaway scenario.

POF₃

Andersson 2013 found the FTIR measurements show production of HF in all tests, but POF₃ could not be detected. The high dilution in the exhaust duct means that POF₃ might have been produced but not detected by the FTIR. Assuming that the ratio between HF and POF₃ concentration was 20 as seen in the spray-tests with the cone calorimeter, that would correspond with maximum POF₃-concentrations below 1 ppm in tests 1-2 and 2.5 ppm in tests 3-5 which is below the quantification limit (6 ppm) for the FTIR. POF₃ was detected in all the small scale tests using pure electrolyte. However, no POF₃ was detected in the tests on cells. Similarly, Larsson 2017 found that for all tested battery types and selected SOC-levels, POF₃ could only be measured quantitatively for type A (lithium cobalt oxide) battery cells at 0% state of charge (SOC). Repeated measurements confirmed the presence of POF₃ only for type A and only for 0% SOC. No POF₃ could thus be detected in any of the other tests (including LFP). Therefore, POF₃ was not included in this analysis.

5.2 Emissions

Battery cell malfunctions, such as thermal runaway events, can result in the release of toxic emissions and/or flammable gas mixtures to the atmosphere. For LFP batteries, the UL9540A testing, the LSBT, and applicable literature indicated that the primary toxic pollutants could be any of the pollutants listed in Table 1. The emissions analyzed in the cell-level UL9540A were scaled up to an entire unit (4,992 cells). Benzene and formaldehyde emissions results from the LSBT were used as they were most representative. Additional pollutants were evaluated from the literature review and scaled based off the mass of 4,992 cells. However, only 11 of these pollutants are TACs (that have an acute REL or AEGL) that could be potentially released during a thermal runaway event within a BESS that may have an impact on nearby receptors. The TACs include propane, butane, CO, HF, hydrogen cyanide, hydrochloric acid, sulfur dioxide, nitrogen dioxide, toluene, benzene, and formaldehyde. While emission factors for volatile organic compounds, phosphoryl fluoride, and PM are included for disclosure purposes, there was no applicable threshold to compare them to. Detailed emission calculations are included in Attachment A.

5.3 Dispersion Modeling

Air dispersion models calculate the atmospheric transport and fate of pollutants from the emission source. The models calculate the concentration of selected pollutants at specific downwind ground-level points, such as residential or school receptors. The transformation (fate) of an airborne pollutant, its movement with the prevailing winds (transport), its crosswind and vertical movement due to atmospheric turbulence (dispersion), and its removal due to dry and wet deposition are influenced by the pollutant's physical and chemical properties, and by meteorological and environmental conditions. Factors such as distance from the source to the receptor, meteorological conditions, intervening land use and terrain, pollutant release characteristics, and background pollutant concentrations affect the predicted air concentration of an air pollutant. Air dispersion models have the capability to take all of these factors into consideration when calculating downwind ground-level pollutant concentrations.

A dispersion modeling analysis was conducted for TACs emitted from a thermal runaway event on proximate receptors. The dispersion modeling was performed using the American Meteorological Society/EPA Regulatory Model (AERMOD), which the EPA approved for atmospheric dispersion of emissions. AERMOD is a steady-state Gaussian plume model that incorporates air dispersion based on planetary boundary layer turbulence structure and scaling concepts, including treatment of surface and elevated sources, building downwash, and simple and complex terrain. While, AERMOD was developed for uses such as Clean Air Act New Source Review permitting and does not account for any chemical reactivity that may occur or interaction between chemicals like a fire dynamics simulator may, the AERMOD analyses are nevertheless instructive. Accordingly, this analysis should be considered within the context of the limitations of pollutant dispersion within AERMOD in this modeling and the assumptions used for estimating emission rates. In this case, using AERMOD to model reactive compounds, like HF, introduces an additional level of conservatism into the results reported in this analysis because AERMOD:

- Does not account for a compounds high reactivity and solubility, so it ignores rapid loss due to moisture interaction, surface uptake, or chemical transformation, leading to higher modeled airborne concentrations;
- Fire plumes generate intense turbulence and entrainment; AERMOD does not explicitly model this fire induced mixing, which can understate early dilution and overstate ground level concentrations in the modeling outputs;
- Plume rise formulations are stack based and may underpredict effective plume rise for hot, buoyant fires, keeping the plume too low and increasing predicted impacts at nearby receptors; and

- Dry deposition algorithms do not capture rapid near-field scavenging of compounds onto soil, vegetation, or structures, which would reduce airborne concentrations quickly after release.

Principal parameters of the thermal runaway dispersion modeling are presented in Table 2, with complete model results included in Attachment B.

Table 2. AERMOD Principal Parameters - Thermal Runaway Analysis

Parameter	Details
Dispersion Model	The air dispersion model used was AERMOD Version 24142, with the Lakes Environmental Software implementation/user interface, AERMOD View, Version 13.0.0. A unit emission rate (1 gram per second [g/s]) was normalized over each unique source of emissions for the AERMOD run to obtain the “X/Q” values. X/Q is a dispersion factor that is the average effluent concentration normalized by source strength, and is used as a way to simplify the representation of emissions from multiple sources. The maximum concentrations were determined for the 1-hour and 8-hour averaging period.
Meteorological Data	The latest five-year meteorological data (2016-2020) for the Palmdale Station (KPMD) were obtained from CARB and used in the analysis as the most representative data set based on proximity and wind direction. A wind rose is provided for this station in Figure 2.
Urban versus Rural Option	Urban areas typically have more surface roughness, as well as structures and low-albedo surfaces that absorb more sunlight—and thus more heat—relative to rural areas. Based on the land use procedure from 4.4.1 of the OEHHA Guidance Manual, the rural dispersion was appropriate for the Project site (OEHHA 2015).
Terrain Characteristics and Elevation Data	Digital elevation model files were imported into AERMOD so that complex terrain features were evaluated as appropriate, and elevations were assigned to the emission sources and receptors. Digital elevation data were obtained through AERMOD View in the U.S. Geological Survey's National Elevation Dataset format with an approximately 1 arc-second resolution.
Emission Sources and Release Parameters	The thermal runaway event was assumed to occur in the BESS container near the O&M buildings as a worst-case scenario based on the predominant wind direction (blowing from the southwest, as shown in Figure 2) and receptor proximity. The BESS container venting during a thermal runaway was modeled as a buoyant line source, with the following parameters based on the source location and information from the UL9540A test data and PowerTitan 2.0 container specifications: • Base elevation of 926.31 meters; • Vertical stack (vent) height of 2.9 meters; • Container length of 6.058 meters; • Container width of 2.9 meters; • Line source width of 2.4 meters; • Separation between containers of 3 meters; • Gas exit temperature of 1,273.15 Kelvin; • Ambient air temperature of 293.15 Kelvin; • Gas exit velocity of 1 meter per second; and • Buoyancy parameter of 111.53 m⁴/s³.
Variable Emissions	No variable emissions were assumed.
Receptors	A fence line grid of receptors was generated with the following spacing to evaluate potential air pollutant impacts within a 6-mile radius of the Project:

Table 2. AERMOD Principal Parameters - Thermal Runaway Analysis

Parameter	Details
	• 25-meter spacing along the Project fence line; • 25-meter spacing from the facility boundary out to 100 meters; • 50-meter spacing from 100 meters to 250 meters; • 100-meter spacing from 250 meters to 500 meters; • 250-meter spacing from 500 meters to 1,000 meters; • 500-meter spacing from 1,000 meters to 2,000 meters; • 1,500-meter spacing from 2,000 meters to 6,000 meters. • A discrete receptor was placed 10 and 20 meters downwind.

Source: OEHHA 2015.

Notes: AERMOD = American Meteorological Society/EPA Regulatory Model; OEHHA = Office of Environmental Health Hazard Assessment; O&M = operations and maintenance; BESS = battery energy storage system; UTM = Universal Transverse Mercator. See Attachment B for model outputs and parameters.

In order to scale the emission results for benzene and formaldehyde from the LSBT to be used at the Project site, the meteorological data set was filtered for only data between 0 and 2.7 meters per second (identical to the conditions in the LSBT). An AERMOD run was performed with this refined meteorological data set with a discrete receptor located at 10 and 20 meters downwind from the source (to represent the sampling locations from the LSBT). The concentrations of those modeled receptors were used to scale the LSBT results to the most impacted residential receptor.

5.4 Exposure Assessment

Under the worst-case scenario studied, the burning and/or venting of the battery cells due to a battery cell malfunction would result in combustion-related emissions. Inhalation is the main pathway by which these emissions could potentially cause public health impacts.

In March 2015, the OEHHA approved the 2015 Risk Assessment Guidelines Manual (OEHHA 2015). The assessment was prepared following the 2015 Risk Assessment Guidelines Manual. Noncancer acute health risk calculations were performed for the project using ground-level unity emission concentration (X/Q) input from AERMOD. The concentration result from AERMOD was then multiplied by the emission rate of each pollutant to determine the potential Project concentration at the maximally exposed individual receptor. The Project's maximum concentration for each pollutant was then compared to the REL, the AEGL-1, and AAQS, as applicable, which are defined as follows:

- A REL is the concentration level at or below which no adverse non-cancer health effects are anticipated for the specified exposure duration (1-hour for an acute analysis) (OEHHA 2015). RELs are based on the most sensitive, relevant, adverse health effect reported in the medical and toxicological literature. RELs are designed to protect the most sensitive individuals in the population by the inclusion of factors that account for uncertainties as well as individual differences in human susceptibility to chemical exposures. The factors used in the calculation of RELs are meant to err on the side of public health protection in order to avoid underestimation of non-cancer hazards. Exceeding the REL does not automatically indicate an adverse health impact. However, increasing concentrations above the REL value increases the likelihood that the health effect will occur. The noncancer health impact of an inhaled TAC is measured by the hazard quotient, which is the ratio of the ambient concentration of a TAC in units of micrograms per cubic meter ($\mu\text{g}/\text{m}^3$) divided by the REL, also in units of $\mu\text{g}/\text{m}^3$. The REL is typically based on health effects on a particular target organ system, such as the respiratory system, liver, or central nervous system. Hazard quotients of individual TACs are then summed for each target organ system to obtain a hazard index.
- The AEGL-1 is the airborne concentration of a substance above which it is predicted that the general population, including susceptible individuals, could experience notable discomfort, irritation, or certain asymptomatic non-sensory effects. However, the effects are not disabling and are transient and reversible upon cessation of exposure.
- The national and California AAQS have been set, with an adequate margin of safety, at levels above which concentrations could be harmful to human health and welfare. These standards are designed to protect the most sensitive persons from illness or discomfort.

As this is an acute health risk exposure assessment, the maximum 1-hour and 8-hour emission rates from thermal runaway of an entire unit was assumed. The analysis evaluated impacts at nearby receptors.

6 Significance Criteria

The applicable REL or AEGL-1 for each pollutant evaluated in this assessment is shown below in Table 3. For the acute hazard index assessment, a significant impact would be defined as having an acute hazard index of over 1 (OEHHA 2015). Finally, state and federal AAQS for CO, SO₂, and NO₂ are also presented below.

Table 3. Significance Criteria

Chemical Name	REL (µg/m³)	AEGL-1 (µg/m³)	Ambient Air Quality Standard (µg/m³)
Propane	N/A	9,919,571	N/A
Butane	N/A	13,074,029	N/A
Carbon monoxide	23,000	N/A	State 1-hour: 22,900
			Federal 1-hour: 40,100
			State 8-hour: 10,300
			Federal 8-hour: 10,300
Hydrogen fluoride	240	818	N/A
Hydrogen cyanide	340	2,208	N/A
Hydrochloric acid	2,100	2,683	N/A
Sulfur dioxide	660	571	State 1-hour: 288
			Federal 1-hour: 655
Nitrogen dioxide	470	942	State 1-hour: 339
			Federal 1-hour: 188
Benzene	27	166,090	N/A
Formaldehyde	55	1,104	N/A
Toluene	5,000	251,920	N/A

Source: OEHHA 2020; EPA 2024; CARB 2024.
Notes: N/A = not applicable; REL = reference exposure level; AEGL = acute exposure guideline levels; µg/m³ = microgram per cubic meter.

7 Results

Table 4 presents the results of the exposure results of the thermal runaway scenario compared to applicable AEGLs as discussed in Section 5, above.

Table 4. Acute Risk Results

Pollutant	Project Concentration (µg/m³)	AEGL-1 (µg/m³)	Exceeds AEGL?
Propane	75.68	9,919,571	No
Butane	28.19	13,074,029	No

Notes: AEGL = acute exposure guideline levels; µg/m³ = microgram per cubic meter.
Source: See Attachment A.

As shown in Table 4, the results of the acute risk analysis showed that the emissions from a thermal runaway event (assuming an entire unit) would not exceed the AEGL for any pollutant at the maximally exposed receptor. Table 5 presents the acute hazard quotient and index summary.

Table 5. Acute Hazard Quotient and Index Summary

Pollutant	Acute Cardiovascular HQ	Acute Respiratory HQ	Acute Eye HQ	Acute Central Nervous System HQ	Acute Immunological HQ	Acute Reproductive HQ	Acute Blood HQ
Carbon Monoxide	0.09	N/A	N/A	N/A	N/A	N/A	N/A
Hydrogen fluoride	N/A	0.63	0.63	N/A	N/A	N/A	N/A
Hydrogen cyanide	N/A	N/A	N/A	0.12	N/A	N/A	N/A
Hydrochloric acid	N/A	0.02	0.02	N/A	N/A	N/A	N/A
Benzene	N/A	N/A	N/A	N/A	~~0.41~~ 0.42	~~0.41~~ 0.42	~~0.41~~ 0.42
Formaldehyde	N/A	N/A	~~0.11~~ 0.12	N/A	N/A	N/A	N/A
Toluene	N/A	0.003	0.003	0.003	N/A	N/A	N/A
Sulfur dioxide	N/A	0.001	N/A	N/A	N/A	N/A	N/A
Nitrogen dioxide	N/A	0.003	N/A	N/A	N/A	N/A	N/A
Hazard Index	0.09	0.66	0.77	0.12	~~0.41~~0.42	~~0.41~~0.42	~~0.41~~0.42

Notes: N/A = not applicable; REL = reference exposure level; µg/m³ = microgram per cubic meter.

The hazard quotient (HQ) measures the potential risk of non-cancer health effects from exposure to a single chemical, while the hazard index (HI) aggregates the hazard quotients of multiple chemicals affecting the same target organ or system.

Totals may not sum due to rounding.

Source: See Attachment A.

As shown in Table 5, the results of the acute risk analysis showed that the emissions from a thermal runaway event (assuming an entire unit) would not result in an acute hazard index greater than the threshold of 1.0 at the maximally exposed receptor. Results at all other receptors are lower than those presented in Table 5 above. As such, no adverse health effects are anticipated at any receptors from exposure to a thermal runaway event.

The results from the ambient air quality modeling assessment are presented in Table 6.

Table 6. Ambient Air Quality Assessment Results

Impact Parameter	Applicable Standard	Background Concentration (µg/m³)	Project Concentration (µg/m³)	Cumulative Concentration (µg/m³)	AAQS Threshold (µg/m³)
1-hour Carbon Monoxide	State	1,604	2,078.83	3,683	22,900
	Federal	1,604	2,078.83	3,683	40,100
8-hour Carbon Monoxide	State	1,260	1,576.12	2,836	10,300
	Federal	1,260	1,576.12	2,836	10,300
1-hour Sulfur Dioxide	State	20	~~0.79~~ 0.81	21	288
	Federal	20	~~0.79~~ 0.81	21	655
1-hour Nitrogen Dioxide	State	87	~~1.36~~ 39	88	339
	Federal	86	~~1.36~~ 39	88	188

Source: See Attachment A.

Note: $\mu\text{g}/\text{m}^3$ = microgram per cubic meter.

As shown in Table 6, the results of the ambient air quality analysis showed that concentrations at the maximally exposed receptor would be below the 1-hour and 8-hour state and federal AAQS. Therefore, the Project would not cause or contribute to an exceedance of an ambient air quality standard due to a thermal runaway event.

8 Conclusions

As shown in Section 7, the results of the worst-case thermal runaway analysis show that emissions from the BESS would not result in an acute hazard index greater than the threshold of 1, exceed the AEGL, or exceed any AAQS at the maximally exposed receptor, based on the conservative evaluation of a full unit undergoing thermal runaway. The risk calculations are contained in Attachment A and the dispersion modeling outputs are in Attachment B.

The results determined in this worst-case analysis reflect conservative estimates of source emissions and emission release characteristics (assuming consumption of all cell material in a container, ignoring the deposition or adsorption of compounds, the reactivity and solubility of compounds, fire induced mixing, and plume effective fire based plume rise), available meteorological data near the project site, and the use of currently approved air quality models. There are limits to the use of these available tools for such an analysis, as described herein. However, the combined use of the AERMOD dispersion model and the health impact calculations required by OEHHa and AVAQMD tend to over-predict potential impacts such that they produce conservative (i.e., health-protective) results. Accordingly, the health impacts would be less than the less than significant impacts described in this assessment. Furthermore, the assumption of one unit undergoing a complete thermal runaway is highly unlikely based on the UL9540A testing and safety systems in place.

As such, the proposed Project would not result in any significant public health or air quality impacts to proximate sensitive receptors.

Plume Study – Clean Version

MEMORANDUM

To:	California Energy Commission
From:	Prairie Song Reliability Project LLC
Subject:	Plume Study for the Prairie Song Reliability Project
Date:	March 18, 2026
Attachments:	A, Emission Calculations B, Dispersion Modeling Outputs

On January 30, 2026, the Executive Director of the California Energy Commission (CEC) issued a Determination of Complete Application for the Prairie Song Reliability Project (Project). CEC Staff also issued requests for information to further assist CEC Staff in the preparation of a Staff Assessment for the Project.

Information request REV 2 DR PH-2 requested additional analysis of potential worst-case impacts in the event of a potential battery energy storage system (BESS) thermal runaway/fire event. This memorandum provides a supplemental thermal runaway/fire scenario¹ analysis technical memorandum (plume study) for the Project in response to Information request REV 2 DR PH-2. This analysis is in addition to the previously docketed Plume Analysis prepared by Fire & Risk Alliance (TN:264382; Appendix 3.17D) and provides a complementary analysis of fire safety and public health. The contents and organization of this memorandum are as follows: Executive Summary, Project Description, Codes and Standards, Neighboring Uses, General Analysis and Methodology, Significance Criteria, Results, Conclusions, and References Cited.

1 Executive Summary

The Project would involve constructing and operating a BESS within unincorporated Los Angeles County (County), California. This plume study evaluated the Project's potential to cause adverse health effects on nearby receptors in the highly unlikely scenario of a thermal runaway event at the BESS.

This plume study provides a list of the chemical constituents that could be emitted from lithium-iron phosphate (LFP) batteries during a thermal runaway event, based on the Underwriters Laboratories ("UL") 9540A testing, the large-scale burn test (LSBT) report, and a literature review.

The Sungrow PowerTitan 2.0 has been selected for this Project application as a representative system. The UL9540A unit tests for PowerTitan 2.0 showed that three (3) initiating cells went into thermal runaway and

¹ Thermal runaway is a situation where the current flowing through the battery cell during either operation or a short circuit causes the cell temperature to rise to the point where a feedback loop can cause a thermal chain reaction.

propagated to two (2) adjacent cells, for a total of five (5) cells. The LSBT showed that after two (2) heaters forced cells into thermal runaway and sparking devices were used to ignite a fire, the fire slowed down and stopped, even in the absence of all other safety features being disabled. Additional heaters needed to be turned on and kept on to force the full unit to a burn. Therefore, this analysis conservatively assumes an entire unit would be affected (i.e., 4,992 cells), even though the LSBT showed that multiple failures and additional actions by the testers to force a full unit burn were necessary, and therefore presents a very conservative scenario that satisfies the information request for a worst-case analysis.

The potential impacts of toxic air contaminants (TACs) from a thermal runaway event were evaluated using dispersion modeling to calculate offsite concentrations of TACs. The concentrations were then compared to the Office of Environmental Health Hazard Assessment (OEHHA) acute reference exposure levels (RELs), level 1 U.S. Environmental Protection Agency (EPA) Acute Exposure Guideline Levels (AEGLs) if no REL exists, the OEHHA threshold of 1 for the acute hazard quotient, and any ambient air quality standards (AAQS), as applicable. As further discussed herein, emissions calculations indicated that the public health impacts from TACs associated with the worst-case battery cell malfunction scenario were less than significant from a public health perspective.

2 Project Description

The Project would include a 1,150-Megawatt (MW) utility-scale BESS installation designed to support grid reliability, renewable energy integration, and local energy resilience. The primary components of the Project include a containerized BESS facility, operations and maintenance (O&M) buildings, an on-site Project substation, a 500-kilovolt (kV) overhead generation interconnection (gen-tie) transmission line, and interconnection facilities within the existing Southern California Edison (SCE)-owned and operated Vincent Substation.

Electrical energy will be transferred from the existing power grid to the Project for storage and from the Project to the power grid when additional electricity is needed. The Project will provide additional capacity to the electrical grid to assist with serving load during periods of peak demand by charging when demand is low and discharging when demand is high. This operating principle increases the integration of additional intermittent renewable energy, such as wind and solar, in California's energy mix and reduces the need to operate natural gas power plants. The Project will also serve as an additional local/regional capacity resource that will enhance grid reliability, particularly to the Los Angeles Basin local reliability area and may allow for the deferral or avoidance of regional transmission facilities.

The Project will be remotely operated and monitored year-round as well as supported by on-site O&M staff seven (7) days a week. The Project will be available to receive or deliver energy 24 hours a day and 365 days a year. During the operational life of the Project, qualified technicians will inspect the Project facilities and conduct necessary maintenance to ensure reliable and safe operational readiness.

2.1 Battery Technology Overview

The energy storage facility will utilize a modular and containerized BESS. There are several battery cell technologies commercially available, with one of the most common presently being LFP cells, or similar. LFP technology is considered one of the safest, most efficient, and thus commercially financeable energy storage technologies available on the market. The initial Project concept has been developed assuming an LFP technology.

LFP batteries are a type of rechargeable lithium-ion battery that uses iron phosphate as the cathode material and a graphitic carbon electrode with a metallic backing as the anode. They offer several advantages, including a longer lifespan, higher safety, and better discharge capacity compared to traditional lithium-ion batteries. LFP batteries also have a lower environmental impact due to the use of more abundant and less toxic materials like iron and phosphorus.

The Sungrow PowerTitan 2.0 has been selected for this Plume Study as a representative system. The Sungrow PowerTitan 2.0 battery energy storage units are a liquid-cooled system engineered for high safety, efficiency, and rapid deployment. Each PowerTitan 2.0 unit integrates battery modules, Power Conversion Systems (PCS), HVAC, fire suppression systems, and Battery Energy Management System (BEMS) into a pre-assembled, containerized format. The PowerTitan 2.0 container enclosure protects the batteries from mechanical damage and weather conditions and provides a rigid metal frame to house six (6) racks of eight (8) modules, with each module containing 104 cells. This plug-and-play architecture reduces on-site installation time by up to 80% compared to conventional systems and minimizes the need for field wiring or battery handling (Sungrow 2024).

The PowerTitan 2.0 employs LFP battery chemistry, chosen for its superior thermal stability and resistance to thermal runaway. The olivine crystal structure of LFP provides strong covalent bonding between iron and phosphate ions, which stabilizes the cathode and prevents oxygen release during thermal decomposition, significantly reducing the risk of combustion (Jie 2024). The system's liquid cooling technology maintains optimal cell temperatures across a wide range of environmental conditions, from -30°C to +55°C, and supports high-density deployments without compromising safety. Each unit is National Fire Protection Association (NFPA) compliant, UL9540A-tested, and includes multi-level protection features such as gas detection, thermal sensors, and automatic fire suppression systems (Sungrow 2024).

Recent research into thermal runaway behavior confirms the advantages of LFP chemistry in large-scale applications. Compared to nickel manganese cobalt (NMC)-based systems, LFP batteries exhibit higher thermal runaway onset temperatures, lower peak heat release rates, and slower propagation between cells. The structural stability of LFP translates into a thermal runaway threshold that is typically above 270°C compared to around 150–200°C for NMC. The electrochemical potential of LFP is lower than that of NMC, resulting in a lower nominal cell voltage (approximately 3.2 V versus 3.6–3.7 V for NMC) and consequently lower energy density. LFP cells exhibit superior cycle life, often exceeding 4,000 cycles at 80% depth of discharge, and maintain performance across a wider range of temperatures. LFP cells are also less prone to capacity fade, which not only improves energy performance but also reduces thermal stress on the batteries (Preger et al. 2020). From a safety engineering perspective, the differences in thermal behavior are critical. NMC cells require more aggressive thermal management and are more likely to propagate failure across adjacent cells if a single cell enters thermal runaway. LFP cells, by contrast, tend to fail passively and are less likely to ignite or propagate heat to neighboring cells. This makes LFP a preferred chemistry for stationary applications where safety, longevity, and cost stability are prioritized over compactness. In experimental scenarios involving coupled abuse conditions such as heating combined with overcharge or external short circuit, LFP cells demonstrated delayed ignition, reduced flame height, and lower total heat release. These characteristics are critical in preventing cascading failures in densely packed installations.

The Project's design reflects these safety priorities. The PowerTitan 2.0 units are deployed in rows with physical separation, allowing for effective containment of any thermal event. The system's integrated monitoring and control platform enables real-time diagnostics, predictive maintenance, and remote shutdown capabilities. This level of visibility and control is essential for managing risk and ensuring compliance with California's evolving BESS safety regulations.

The United States' (US) installations of advanced energy storage — almost entirely lithium-ion battery systems — surpassed 3 gigawatt (GW) in the second quarter of 2024 according to research firm Wood Mackenzie Power & Renewables, which forecasts, then records and analyses energy storage deployments (Utility Dive News 2024). California had approximately 13,000 GW of utility scale battery storage installed as of 2024 and is projected to reach 54,000 GW by 2045.

3 Codes and Standards

3.1 Battery Testing Requirements and Regulations

BESS facilities and batteries are subject to several strict safety codes and standards. Some of the relevant codes and standards are discussed below.

Underwriters Laboratories (UL), a globally recognized safety certification company.

UL9540A: Test Method for Evaluating Thermal Runaway Fire Propagation in Battery Energy Storage Systems – this test methodology evaluates the fire characteristics of battery cells, modules, and installations that are purposefully induced into thermal runaway. The data generated can be used to determine the fire and explosion protection required for installation of a BESS.

UL1973: Standard for Batteries for Use in Stationary, Vehicle Auxiliary Power and Light Electric Rail (LER) Applications - This standard evaluates the battery system's ability to safely withstand simulated abuse conditions. This standard evaluates the system based upon the manufacturer's specified charge and discharge parameters. It requires that a BESS is not allowed to be an explosion hazard when exposed to an external fire source and that a single cell failure will not result in a cascading thermal runaway of cells.

UL1741: Inverters, Controllers, Converters, and Interconnection Equipment Standards - These requirements cover inverters, converters, charge controllers, and interconnection system equipment (ISE) intended for use in stand-alone (not grid-connected) or interactive (grid-connected) power systems. Interactive inverters, converters, and ISE are intended to be operated in parallel with an electric power system (EPS) to supply power to common loads.

UL9540: Energy Storage Systems and Equipment – This standard requires compliance with key UL sub-standards as well as standards from other recognized parties to certify safety of an integrated energy storage system.

International Fire Code (IFC): IFC is the model up-to-date fire code addressing conditions hazardous to life and property from fire, explosion, handling or use of hazardous materials and the use and occupancy of buildings and premises.

IFC specifies minimum size requiring permits (Lithium, all types, 20 kilowatt-hours (kWh)), specifies maximum limits on sizing for battery systems (Lithium all type, 50 kwh each array), seismic and structural design, spacing (minimum 3 feet separation of arrays), vehicle impact protection, testing, maintenance and repairs, maximum quantities within a building (Lithium of 600 kwh), battery management system (BMS)

monitoring, shutdown and notification requirements, automatic smoke detector requirements, automatic fire sprinkler systems, and ventilation specifications.

California Fire Code (CFC): The CFC is promulgated in the California Code of Regulations Title 24, Part 9, and contains regulations consistent with nationally recognized and accepted practices for safeguarding life and property from the following hazards:

- Fire and explosion
- Dangerous conditions arising from the storage, handling, and use of hazardous materials and devices
- Hazardous conditions in the use or occupancy of buildings or premises

The CFC also contains provisions to assist emergency response personnel. The CFC is a fully integrated code based on the IFC, described previously.

CFC Chapter 12 (Energy Systems): Chapter 12 was added to the CFC to address standby and emergency power, portable generators, photovoltaic systems, fuel cell energy systems, and energy storage systems. From CFC Chapter 12, a BESS must meet the provisions and requirements of Sections 1201 (General) and 1207 (Electrical Energy Storage Systems).

Institute of Electrical and Electronics Engineers (IEEE): The world's largest technical professional organization dedicated to advancing technology.

IEEE C2: This Code covers basic provisions for safeguarding of persons from hazards arising from the installation, operation, or maintenance of (1) conductors and equipment in electric supply stations, and (2) overhead and underground electric supply and communication lines. It also includes work rules for the construction, maintenance, and operation of electric supply and communication lines and equipment. The Code is applicable to the systems and equipment operated by utilities, or similar systems and equipment, of an industrial establishment or complex under the control of qualified persons.

National Fire Protection Association (NFPA): NFPA is an international nonprofit that develops standards to minimize risks and losses from fire, electrical hazards, and other dangers.

NFPA 70: National Electrical Code, addresses electrical design, installation, and inspection.

NFPA 550: Guide to Fire Safety Concepts Tree for Protecting Energy Systems - addresses issues such as utilizing BMS and compatible equipment, ventilation as needed, fire resistive separation, array spacing, and signage.

NFPA 855: Standard for the Installation of Stationary Energy Storage Systems - offers comprehensive criteria for the fire protection of BESS installations based on the technology used in BESS, the setting where the technology is being installed, the size and separation of BESS installations, and the fire suppression and control systems in place. Additional considerations include ventilation, detection, signage, listings, and emergency operations responding to BESS emergencies.

California Public Utilities Commission (CPUC): CPUC is a regulatory agency responsible for overseeing utility services and infrastructure in California, including electricity, natural gas, telecommunications, water, and transportation.

Its mission is to ensure that Californians receive safe, reliable, and affordable utility services. The CPUC sets standards, conducts inspections, and enforces regulations to maintain service quality and public safety. It also addresses consumer complaints, offers financial assistance programs, and promotes clean energy initiatives.

CPUC General Order 167-C: Operational standards and maintenance protocols for electric generation facilities and energy storage systems in California. It emphasizes the importance of reliability and safety, detailing requirements for regular inspections, performance monitoring, and reporting. The order mandates that facilities adhere to specific guidelines to ensure consistent operation and prevent outages, with a focus on maintaining equipment and infrastructure. Compliance is enforced through periodic audits and penalties for non-compliance, aiming to uphold high standards in the state's energy sector.

4 Neighboring Uses

Some land uses are considered more sensitive to changes in air quality than others, depending on the population groups and the activities involved. People most likely to be affected by air pollution include children, the elderly, athletes, and people with cardiovascular and chronic respiratory diseases. Facilities and structures where these air-pollution-sensitive people live or spend considerable amounts of time are known as “sensitive receptors.” Land uses where air-pollution-sensitive individuals are most likely to spend time include schools and schoolyards, parks and playgrounds, daycare centers, nursing homes, hospitals, and residential communities (sensitive sites or sensitive land uses) (CARB 2005). The Antelope Valley Air Quality Management District (AVAQMD) identifies residences, daycare centers, playgrounds, and medical facilities as sensitive receptors for the purposes of identifying air quality impacts (AVAQMD 2016).

The closest sensitive receptors to the Project site are residences located immediately adjacent to the west (along Malinta Avenue), north (along Tortuga Street and Soledad Canyon Road), and south (across Soledad Canyon Road) of the BESS facility Project site boundary. The nearest school is the Meadowlark Elementary School, located approximately two (2) miles to the west of the proposed BESS facility. This analysis also assesses impacts to non-sensitive receptor commercial uses, with the nearest being approximately 815 feet to the north of the Project. The location of the neighboring uses by type are shown in Figure 1.

5 General Analysis and Methodology

As described previously in Section 3, Codes and Standards, based on the requirements in Chapter 12 of the California Fire Code and the NFPA 855 standard, the risk of fire, explosion, and toxic release are minimized by the installation of energy management systems, fire detection and protection systems, explosion control systems, and ventilation. Further protection to the surrounding properties can be provided through proper pre-planning and coordination with local emergency agencies. Pre-planning for BESS facilities can be accomplished through the preparation of a Hazard Mitigation Analysis, which is used to evaluate the consequences associated with a potential project system failure and how those potential failures meet local codes and standards, in this case the Los Angeles County Fire Code. An additional pre-planning best practice is the preparation of an Emergency Response and Emergency Action Plan (ERP), which is required by Public Utilities Code Section 761.3. ERPs consider responses to potential offsite impacts, including poor air quality, and include procedures that provide for the safety of surrounding properties.

During normal operations, there will be no toxic air emissions from the Project. However, to evaluate potential worst-case public health impacts for this analysis, this report assumes the highly unlikely event of multiple safety and ventilation system failures so that a battery cell malfunction is not controlled. It is also assumed that the battery cell malfunction continues throughout the entire unit, consuming the totality of every cell until the reaction ceases. Based on the results of the UL9450A testing and the LSBT assumptions of multiple failures and additional actions by the testers required to force a full unit burn, the assumption that the totality of every cell is consumed is very conservative.

In the event of a battery cell malfunction, it is possible that a thermal runaway event and/or a fire could occur. While modern-day systems are designed to contain such fires within a single battery module or cabinet, if a fire does occur, some limited pollutants could be emitted to the atmosphere. Unlike other structural fires, the primary emissions from a thermal runaway event of a battery energy systems are flammable gases, which burn or dissipate within the vicinity of the battery unit. The majority of the battery structure is non-combustible.

To provide the worst-case scenario requested, it is assumed that the release of specific pollutants to the atmosphere would occur within a relatively short and concentrated period of time, based on the 1-hour exposure of TAC thresholds. The emissions modeled for a thermal runaway were based on the cell level UL9540A testing, the LSBT report, and applicable literature. Per the LSBT, emissions from a thermal runaway were observed for 28.03 hours for an entire unit, which were normalized to an hourly rate for the thermal runaway analysis (Sungrow 2025). Emission rates from the cell level UL9540A testing were extrapolated to an entire unit (4,992 cells). The actual rate of release would be dependent on energy stored within the individual battery system.

In the unlikely event of a battery cell malfunction, the primary emissions released would be carbon dioxide (CO₂), hydrogen (H₂), and carbon monoxide (CO), along with lesser amounts of other compounds. Table 1 provides a list of chemical constituents that could be emitted from LFP batteries during a thermal runaway event, based on the UL9540A testing, LSBT, and literature review.

Table 1. Potential Chemical Constituents Emitted from LFP Batteries

Pollutant	Chemical Formula	CAS Number	Measured Percent
UL9540A Testing			
Methane	CH ₄	74-82-8	6.421%
Acetylene	C ₂ H ₂	74-86-2	0.339%

Table 1. Potential Chemical Constituents Emitted from LFP Batteries

Pollutant	Chemical Formula	CAS Number	Measured Percent
Ethylene	C ₂ H ₄	74-85-1	3.827%
Ethane	C ₂ H ₆	74-84-0	0.996%

Pollutants emitted and % composition based on the Cell Test Report UL9540A, large scale burn test, and literature review.

The potential impacts of TACs from a thermal runaway event were evaluated using dispersion modeling to calculate offsite concentrations of TACs. The concentrations were then compared to the OEHHA acute RELs, AEGLs if no REL exists, and the OEHHA threshold of 1 for the acute hazard quotient, and any AAQS, as applicable. The methodology of each source of emission factors is discussed further in this section.

5.1 Thermal Runaway Emission Sources

5.1.1 UL9540A Testing

The UL9540A unit tests for the Sungrow PowerTitan 2.0 forced initiating cells into thermal runaway, through the addition of heat via glass fiber thermocouples. No external flaming or flame venting occurred during the UL9540A testing at the unit level. There are no single failures identified in the failure modes and effects analysis, documented in available BESS failure literature, or reported in anecdotal case reports that show or support a mechanism of failure that would cause thermal runaway to occur in all cells within a single module simultaneously, nor propagate to other modules in a rack. As such, there is no existing test data or established failure mechanism in the UL9540A reports that documented all 104 cells within a module or 4,992 cells within a BESS to undergo thermal runaway from a single failure. Rather, thermal runaway propagation from cell to cell would remain a direct component of battery gas release timing, release conditions, and associated consequences for all potential single failures initiating thermal runaway and battery gas venting in the PowerTitan 2.0 BESS. The UL9540A test was used as the basis for emissions of methane, acetylene, ethylene, ethane, propylene, propane, isobutane, trans butene, n-butene, pentane, isopentane, 2-methyl-1,3-butadiene, carbon monoxide, carbon dioxide, and hydrogen.

5.1.2 Large Scale Burn Test

A LSBT was conducted on the Sungrow PowerTitan 2.0 where an entire unit was forced into a thermal runaway (Sungrow 2025). The ambient conditions during the testing showed wind speed between 0 and 2.7 meters per second (m/s). The CSA TS-800 standard allows up to 2.7 m/s. The wind direction was predominantly blowing from the south, west, and then east towards the end of the test. The temperature ranged from 13 to 25°C during the test (CSA standard allows 10 to 40°C). The humidity varied from 45% to 87% (CSA standard allows below 90%). A continuous gas sampling system using a Raman spectrometer was used to analyze vent gases. The following gases were monitored during the test progression in a continuous manner: H₂, O₂, CO₂, CO, and HC and H₂S. In addition, 32 discrete gas samples were collected at 10 and 20 meters downwind into sample canisters to have gas analysis performed post-test to determine concentrations of gases present. Gas chromatography-mass spectrometry (GC-MS), thermal desorption gas chromatography with mass spectrometric detection (TDS-GCMS), ion chromatography (IC), and gas chromatography-flame ionization detection (GC-FID) were used to analyze the compositions and concentrations in volume. Electric thin-film heaters were used to induce the thermal runaway in one module and sparkers were used to ignite the gases. Even though all the safety mechanisms were turned off, the first fire slowed and stopped. Later in the test, additional heaters in the module were turned on to force the rest of the module into thermal runaway. Deflagration panels worked successfully and the fire in the container did not spread to any other container or damage the internal modules of any other containers. The LSBT was used as the basis for emissions of benzene, formaldehyde, toluene, sulfur dioxide, and nitrogen dioxide.

5.1.3 Literature Review

A literature review was conducted to identify other potential emissions from a LFP thermal runaway that were not identified in the UL9540A testing and LSBT. The literature review focused on studies that were representative of the chemistry (LFP) and cell type (cylindrical). It should be noted that there were no publicly available LSBT studies to review outside that of the Sungrow PowerTitan 2.0. The available studies were conducted at the cell level with much smaller capacity cells than the Project (3.2-20 ampere-hours compared to 314 ampere-hours). The literature review was used as the basis for emissions of hydrogen fluoride, hydrogen cyanide, and hydrochloric acid.

Hydrogen Fluoride (HF)

Larsson et al showed that when testing multiple LFP cells with different sizes and form factors, reported hydrogen fluoride (HF) results had an order-of-magnitude variability at similar capacities and the HF yield depends on venting dynamics, construction, and sampling method, not capacity (Larsson et al 2017). FTIR measurements represent HF that remains in the air and is relevant to inhalation exposure, whereas water-washing or impinger methods capture total fluorine, including fluorinated intermediates (e.g., POF_3) that hydrolyze to HF during sampling and would not remain fully airborne. This report explicitly acknowledges this distinction and adopts FTIR based yields for air dispersion modeling to avoid systematic overprediction of airborne HF. It was also observed that HF originates from fluorine-based materials, not stored energy. Therefore, the cell-level results do not scale proportionally with nominal capacity; rather, they scale with electrolyte mass, electrode surface area, and total materials mass. HF generated during lithium-ion battery fires is highly water soluble and reactive and is rapidly scavenged by fire suppression water, enclosure surfaces, and soot (EPA 1993). Experimental studies of battery fires and industrial HF releases show that only a fraction of generated HF remains airborne. Larsson et al also observed that there was a 75% reduction in HF emissions in cylindrical cells compared to pouch, due to increased mechanical confinement, restricted vent paths, and partial retention or internal recombination of fluorinated species. As the Sungrow PowerTitan 2.0 includes prismatic cells, a conservative reduction factor of 0.5 was applied to the HF emission rates (which were based on pouch cells) in the analysis. While HF was not evaluated in the UL9540A or LSBT, the emission factor of 1,264 milligrams per cubic meter was included herein as the analysis of a 243Ah pouch cell is the most representative of the Project's chemistry and configuration (Liu et al 2021).

Hydrogen Cyanide (HCN)

HCN is a recognized toxic byproduct of LFP thermal runaway, formed primarily from the thermal decomposition and combustion of nitrogen containing electrolytes, binders, and polymeric components within lithium-ion cells. Experimental studies and consequence modeling analyses show that during thermal runaway—especially when cell vent gases ignite or when plastics and electrolytes burn—HCN can be released (Kwon et al 2024). In laboratory thermal runaway tests, HCN emissions are limited in total mass and duration because they involve only single cells or small modules under controlled ventilation, making the results useful for identifying formation mechanisms but not for predicting real world exposure. Therefore, the application of laboratory testing is considered conservative. HCN emissions were modeled using average volumetric results from DNV GL 2019.

Hydrogen Chloride (HCl)

HCL emissions were modeled using an emission factor of 170 mg/kg, also expressed per unit mass of battery material (Liu et al 2021). HCl is consistently a minor constituent of LFP vent gas, with mass release rates substantially lower than HF and rarely controlling exposure distances in dispersion modeling. FTIR based measurements reported by Larsson et al. show limited HCl formation during LFP events, reflecting the absence of chlorine rich cathode materials and minimal contribution from enclosure materials under nonflaming conditions (Larsson et al., 2017).

Additional testing summarized by DNV GL 2019 confirms that elevated HCl concentrations are primarily associated with combustion of external chlorinated plastics rather than intrinsic battery materials, which is not assumed in the provided AERMOD analysis. The selected HCl value therefore represents the upper mid range of gas phase HCl reported for LFP cells and conservatively accounts for airborne irritant potential without assuming combustion of nonbattery materials.

Acrolein

Two studies detected acrolein from lithium ion fire cell releases, Long et al., 2013 and Nedjalkov et al., 2016. Long et al studied burns for electric vehicles (EV) of unknown chemistry. The analysis consisted of full-scale fire testing on a battery pack and an EV. Acrolein was detected, but measurements were not recorded. Due to uncertainty on battery type, a lack of applicability between a BESS container and an EV, and a lack of reported numbers, data from the Long study cannot be applied to this analysis. Nedjalkov studied NMC cells only. Our literature review did not reveal any studies showing acrolein production during an LFP thermal event, as such acrolein was not included in the plume analysis.

Carbonyl Fluoride (COF₂)

Our literature review could not find any studies that measured COF₂ production in an LFP thermal event that would be usable for modeling purposes. The absence of COF₂ in LFP thermal runaway experiments is chemically consistent. COF₂ is highly reactive and hydrolyzes rapidly to HF and CO₂ in the presence of moisture (Bugryniec et al 2024). Battery fire environments contain water vapor, combustion radicals, and hot surfaces, all of which favor rapid destruction of COF₂. LFP batteries generally do not contain fluorinated cathode materials, limiting fluorine availability to electrolyte components, which preferentially form HF. As a result, even if COF₂ were transiently formed at the molecular scale, it would not persist as a measurable airborne toxicant, and therefore was not included in our plume study.

Particulate Matter (PM)

The particulate matter (PM) emission rates reported in Claassen 2024 are not representative of a full BESS thermal runaway event because the experiments were conducted on individual LFP and lithium-cobalt oxide cells rather than multicell modules or racks, which means the experiments lack the complex thermal propagation behavior, cascading failures, and cumulative energy release that occur in real BESS incidents. The cells were externally heated on a hot plate rather than failing from realistic mechanisms such as internal shorts, propagation, or overcharge, which strongly influences the type and quantity of emitted particles. The tests occurred inside an open, ventilated burn chamber, without the confinement, restricted airflow, gas buildup, enclosure heating, and secondary combustion typical of BESS cabinets, all of which significantly alter aerosol formation and PM concentrations. For these reasons, while the study provides valuable insights into cell level particle emissions, the measured PM rates cannot be applied to a container level BESS thermal runaway scenario.

POF₃

Andersson 2013 found the FTIR measurements show production of HF in all tests, but POF₃ could not be detected. The high dilution in the exhaust duct means that POF₃ might have been produced but not detected by the FTIR. Assuming that the ratio between HF and POF₃ concentration was 20 as seen in the spray-tests with the cone calorimeter, that would correspond with maximum POF₃-concentrations below 1 ppm in tests 1-2 and 2.5 ppm in tests 3-5 which is below the quantification limit (6 ppm) for the FTIR. POF₃ was detected in all the small scale tests using pure electrolyte. However, no POF₃ was detected in the tests on cells. Similarly, Larsson 2017 found that for all tested battery types and selected SOC-levels, POF₃ could only be measured quantitatively for type A (lithium cobalt oxide) battery cells at 0% state of charge (SOC). Repeated measurements confirmed the presence of POF₃ only for type A and only for 0% SOC. No POF₃ could thus be detected in any of the other tests (including LFP). Therefore, POF₃ was not included in this analysis.

5.2 Emissions

Battery cell malfunctions, such as thermal runaway events, can result in the release of toxic emissions and/or flammable gas mixtures to the atmosphere. For LFP batteries, the UL9540A testing, the LSBT, and applicable literature indicated that the primary toxic pollutants could be any of the pollutants listed in Table 1. The emissions analyzed in the cell-level UL9540A were scaled up to an entire unit (4,992 cells). Benzene and formaldehyde emissions results from the LSBT were used as they were most representative. Additional pollutants were evaluated from the literature review and scaled based off the mass of 4,992 cells. However, only 11 of these pollutants are TACs (that have an acute REL or AEGL) that could be potentially released during a thermal runaway event within a BESS that may have an impact on nearby receptors. The TACs include propane, butane, CO, HF, hydrogen cyanide, hydrochloric acid, sulfur dioxide, nitrogen dioxide, toluene, benzene, and formaldehyde. While emission factors for volatile organic compounds, phosphoryl fluoride, and PM are included for disclosure purposes, there was no applicable threshold to compare them to. Detailed emission calculations are included in Attachment A.

5.3 Dispersion Modeling

Air dispersion models calculate the atmospheric transport and fate of pollutants from the emission source. The models calculate the concentration of selected pollutants at specific downwind ground-level points, such as residential or school receptors. The transformation (fate) of an airborne pollutant, its movement with the prevailing winds (transport), its crosswind and vertical movement due to atmospheric turbulence (dispersion), and its removal due to dry and wet deposition are influenced by the pollutant's physical and chemical properties, and by meteorological and environmental conditions. Factors such as distance from the source to the receptor, meteorological conditions, intervening land use and terrain, pollutant release characteristics, and background pollutant concentrations affect the predicted air concentration of an air pollutant. Air dispersion models have the capability to take all of these factors into consideration when calculating downwind ground-level pollutant concentrations.

A dispersion modeling analysis was conducted for TACs emitted from a thermal runaway event on proximate receptors. The dispersion modeling was performed using the American Meteorological Society/EPA Regulatory Model (AERMOD), which the EPA approved for atmospheric dispersion of emissions. AERMOD is a steady-state Gaussian plume model that incorporates air dispersion based on planetary boundary layer turbulence structure and scaling concepts, including treatment of surface and elevated sources, building downwash, and simple and complex terrain. While, AERMOD was developed for uses such as Clean Air Act New Source Review permitting and does not account for any chemical reactivity that may occur or interaction between chemicals like a fire dynamics simulator may, the AERMOD analyses are nevertheless instructive. Accordingly, this analysis should be considered within the context of the limitations of pollutant dispersion within AERMOD in this modeling and the assumptions used for estimating emission rates. In this case, using AERMOD to model reactive compounds, like HF, introduces an additional level of conservatism into the results reported in this analysis because AERMOD:

- Does not account for a compounds high reactivity and solubility, so it ignores rapid loss due to moisture interaction, surface uptake, or chemical transformation, leading to higher modeled airborne concentrations;
- Fire plumes generate intense turbulence and entrainment; AERMOD does not explicitly model this fire induced mixing, which can understate early dilution and overstate ground level concentrations in the modeling outputs;
- Plume rise formulations are stack based and may underpredict effective plume rise for hot, buoyant fires, keeping the plume too low and increasing predicted impacts at nearby receptors; and

- Dry deposition algorithms do not capture rapid near-field scavenging of compounds onto soil, vegetation, or structures, which would reduce airborne concentrations quickly after release.

Principal parameters of the thermal runaway dispersion modeling are presented in Table 2, with complete model results included in Attachment B.

Table 2. AERMOD Principal Parameters - Thermal Runaway Analysis

Parameter	Details
Dispersion Model	The air dispersion model used was AERMOD Version 24142, with the Lakes Environmental Software implementation/user interface, AERMOD View, Version 13.0.0. A unit emission rate (1 gram per second [g/s]) was normalized over each unique source of emissions for the AERMOD run to obtain the “X/Q” values. X/Q is a dispersion factor that is the average effluent concentration normalized by source strength, and is used as a way to simplify the representation of emissions from multiple sources. The maximum concentrations were determined for the 1-hour and 8-hour averaging period.
Meteorological Data	The latest five-year meteorological data (2016-2020) for the Palmdale Station (KPMD) were obtained from CARB and used in the analysis as the most representative data set based on proximity and wind direction. A wind rose is provided for this station in Figure 2.
Urban versus Rural Option	Urban areas typically have more surface roughness, as well as structures and low-albedo surfaces that absorb more sunlight—and thus more heat—relative to rural areas. Based on the land use procedure from 4.4.1 of the OEHHA Guidance Manual, the rural dispersion was appropriate for the Project site (OEHHA 2015).
Terrain Characteristics and Elevation Data	Digital elevation model files were imported into AERMOD so that complex terrain features were evaluated as appropriate, and elevations were assigned to the emission sources and receptors. Digital elevation data were obtained through AERMOD View in the U.S. Geological Survey's National Elevation Dataset format with an approximately 1 arc-second resolution.
Emission Sources and Release Parameters	The thermal runaway event was assumed to occur in the BESS container near the O&M buildings as a worst-case scenario based on the predominant wind direction (blowing from the southwest, as shown in Figure 2) and receptor proximity. The BESS container venting during a thermal runaway was modeled as a buoyant line source, with the following parameters based on the source location and information from the UL9540A test data and PowerTitan 2.0 container specifications: • Base elevation of 926.31 meters; • Vertical stack (vent) height of 2.9 meters; • Container length of 6.058 meters; • Container width of 2.9 meters; • Line source width of 2.4 meters; • Separation between containers of 3 meters; • Gas exit temperature of 1,273.15 Kelvin; • Ambient air temperature of 293.15 Kelvin; • Gas exit velocity of 1 meter per second; and • Buoyancy parameter of 111.53 m⁴/s³.
Variable Emissions	No variable emissions were assumed.
Receptors	A fence line grid of receptors was generated with the following spacing to evaluate potential air pollutant impacts within a 6-mile radius of the Project:

Table 2. AERMOD Principal Parameters - Thermal Runaway Analysis

Parameter	Details
	• 25-meter spacing along the Project fence line; • 25-meter spacing from the facility boundary out to 100 meters; • 50-meter spacing from 100 meters to 250 meters; • 100-meter spacing from 250 meters to 500 meters; • 250-meter spacing from 500 meters to 1,000 meters; • 500-meter spacing from 1,000 meters to 2,000 meters; • 1,500-meter spacing from 2,000 meters to 6,000 meters. • A discrete receptor was placed 10 and 20 meters downwind.

Notes: AERMOD = American Meteorological Society/EPA Regulatory Model; OEHHA = Office of Environmental Health Hazard Assessment; O&M = operations and maintenance; BESS = battery energy storage system; UTM = Universal Transverse Mercator. See Attachment B for model outputs and parameters.

In order to scale the emission results for benzene and formaldehyde from the LSBT to be used at the Project site, the meteorological data set was filtered for only data between 0 and 2.7 meters per second (identical to the conditions in the LSBT). An AERMOD run was performed with this refined meteorological data set with a discrete receptor located at 10 and 20 meters downwind from the source (to represent the sampling locations from the LSBT). The concentrations of those modeled receptors were used to scale the LSBT results to the most impacted residential receptor.

5.4 Exposure Assessment

Under the worst-case scenario studied, the burning and/or venting of the battery cells due to a battery cell malfunction would result in combustion-related emissions. Inhalation is the main pathway by which these emissions could potentially cause public health impacts.

In March 2015, the OEHHA approved the 2015 Risk Assessment Guidelines Manual (OEHHA 2015). The assessment was prepared following the 2015 Risk Assessment Guidelines Manual. Noncancer acute health risk calculations were performed for the project using ground-level unity emission concentration (X/Q) input from AERMOD. The concentration result from AERMOD was then multiplied by the emission rate of each pollutant to determine the potential Project concentration at the maximally exposed individual receptor. The Project's maximum concentration for each pollutant was then compared to the REL, the AEGL-1, and AAQS, as applicable, which are defined as follows:

- A REL is the concentration level at or below which no adverse non-cancer health effects are anticipated for the specified exposure duration (1-hour for an acute analysis) (OEHHA 2015). RELs are based on the most sensitive, relevant, adverse health effect reported in the medical and toxicological literature. RELs are designed to protect the most sensitive individuals in the population by the inclusion of factors that account for uncertainties as well as individual differences in human susceptibility to chemical exposures. The factors used in the calculation of RELs are meant to err on the side of public health protection in order to avoid underestimation of non-cancer hazards. Exceeding the REL does not automatically indicate an adverse health impact. However, increasing concentrations above the REL value increases the likelihood that the health effect will occur. The noncancer health impact of an inhaled TAC is measured by the hazard quotient, which is the ratio of the ambient concentration of a TAC in units of micrograms per cubic meter ($\mu\text{g}/\text{m}^3$) divided by the REL, also in units of $\mu\text{g}/\text{m}^3$. The REL is typically based on health effects on a particular target organ system, such as the respiratory system, liver, or central nervous system. Hazard quotients of individual TACs are then summed for each target organ system to obtain a hazard index.
- The AEGL-1 is the airborne concentration of a substance above which it is predicted that the general population, including susceptible individuals, could experience notable discomfort, irritation, or certain asymptomatic non-sensory effects. However, the effects are not disabling and are transient and reversible upon cessation of exposure.
- The national and California AAQS have been set, with an adequate margin of safety, at levels above which concentrations could be harmful to human health and welfare. These standards are designed to protect the most sensitive persons from illness or discomfort.

As this is an acute health risk exposure assessment, the maximum 1-hour and 8-hour emission rates from thermal runaway of an entire unit was assumed. The analysis evaluated impacts at nearby receptors.

6 Significance Criteria

The applicable REL or AEGL-1 for each pollutant evaluated in this assessment is shown below in Table 3. For the acute hazard index assessment, a significant impact would be defined as having an acute hazard index of over 1 (OEHHA 2015). Finally, state and federal AAQS for CO, SO₂, and NO₂ are also presented below.

Table 3. Significance Criteria

Chemical Name	REL (µg/m³)	AEGL-1 (µg/m³)	Ambient Air Quality Standard (µg/m³)
Propane	N/A	9,919,571	N/A
Butane	N/A	13,074,029	N/A
Carbon monoxide	23,000	N/A	State 1-hour: 22,900
			Federal 1-hour: 40,100
			State 8-hour: 10,300
			Federal 8-hour: 10,300
Hydrogen fluoride	240	818	N/A
Hydrogen cyanide	340	2,208	N/A
Hydrochloric acid	2,100	2,683	N/A
Sulfur dioxide	660	571	State 1-hour: 288
			Federal 1-hour: 655
Nitrogen dioxide	470	942	State 1-hour: 339
			Federal 1-hour: 188
Benzene	27	166,090	N/A
Formaldehyde	55	1,104	N/A
Toluene	5,000	251,920	N/A

Source: OEHHA 2020; EPA 2024; CARB 2024.
Notes: N/A = not applicable; REL = reference exposure level; AEGL = acute exposure guideline levels; µg/m³ = microgram per cubic meter.

7 Results

Table 4 presents the results of the exposure results of the thermal runaway scenario compared to applicable AEGLs as discussed in Section 5, above.

Table 4. Acute Risk Results

Pollutant	Project Concentration (µg/m³)	AEGL-1 (µg/m³)	Exceeds AEGL?
Propane	75.68	9,919,571	No
Butane	28.19	13,074,029	No

Notes: AEGL = acute exposure guideline levels; µg/m³ = microgram per cubic meter.
Source: See Attachment A.

As shown in Table 4, the results of the acute risk analysis showed that the emissions from a thermal runaway event (assuming an entire unit) would not exceed the AEGL for any pollutant at the maximally exposed receptor. Table 5 presents the acute hazard quotient and index summary.

Table 5. Acute Hazard Quotient and Index Summary

Pollutant	Acute Cardiovascular HQ	Acute Respiratory HQ	Acute Eye HQ	Acute Central Nervous System HQ	Acute Immunological HQ	Acute Reproductive HQ	Acute Blood HQ
Carbon Monoxide	0.09	N/A	N/A	N/A	N/A	N/A	N/A
Hydrogen fluoride	N/A	0.63	0.63	N/A	N/A	N/A	N/A
Hydrogen cyanide	N/A	N/A	N/A	0.12	N/A	N/A	N/A
Hydrochloric acid	N/A	0.02	0.02	N/A	N/A	N/A	N/A
Benzene	N/A	N/A	N/A	N/A	0.42	0.42	0.42
Formaldehyde	N/A	N/A	0.12	N/A	N/A	N/A	N/A
Toluene	N/A	0.003	0.003	0.003	N/A	N/A	N/A
Sulfur dioxide	N/A	0.001	N/A	N/A	N/A	N/A	N/A
Nitrogen dioxide	N/A	0.003	N/A	N/A	N/A	N/A	N/A
Hazard Index	0.09	0.66	0.77	0.12	0.42	0.42	0.42

Notes: N/A = not applicable; REL = reference exposure level; $\mu\text{g}/\text{m}^3$ = microgram per cubic meter.

The hazard quotient (HQ) measures the potential risk of non-cancer health effects from exposure to a single chemical, while the hazard index (HI) aggregates the hazard quotients of multiple chemicals affecting the same target organ or system.

Totals may not sum due to rounding.

Source: See Attachment A.

As shown in Table 5, the results of the acute risk analysis showed that the emissions from a thermal runaway event (assuming an entire unit) would not result in an acute hazard index greater than the threshold of 1.0 at the maximally exposed receptor. Results at all other receptors are lower than those presented in Table 5 above. As such, no adverse health effects are anticipated at any receptors from exposure to a thermal runaway event.

The results from the ambient air quality modeling assessment are presented in Table 6.

Table 6. Ambient Air Quality Assessment Results

Impact Parameter	Applicable Standard	Background Concentration ($\mu\text{g}/\text{m}^3$)	Project Concentration ($\mu\text{g}/\text{m}^3$)	Cumulative Concentration ($\mu\text{g}/\text{m}^3$)	AAQS Threshold ($\mu\text{g}/\text{m}^3$)
1-hour Carbon Monoxide	State	1,604	2,078.83	3,683	22,900
	Federal	1,604	2,078.83	3,683	40,100
8-hour Carbon Monoxide	State	1,260	1,576.12	2,836	10,300
	Federal	1,260	1,576.12	2,836	10,300
1-hour Sulfur Dioxide	State	20	0.81	21	288
	Federal	20	0.81	21	655
1-hour Nitrogen Dioxide	State	87	1.39	88	339
	Federal	86	1.39	88	188

Source: See Attachment A.

Note: $\mu\text{g}/\text{m}^3$ = microgram per cubic meter.

As shown in Table 6, the results of the ambient air quality analysis showed that concentrations at the maximally exposed receptor would be below the 1-hour and 8-hour state and federal AAQS. Therefore, the Project would not cause or contribute to an exceedance of an ambient air quality standard due to a thermal runaway event.

8 Conclusions

As shown in Section 7, the results of the worst-case thermal runaway analysis show that emissions from the BESS would not result in an acute hazard index greater than the threshold of 1, exceed the AEGL, or exceed any AAQS at the maximally exposed receptor, based on the conservative evaluation of a full unit undergoing thermal runaway. The risk calculations are contained in Attachment A and the dispersion modeling outputs are in Attachment B.

The results determined in this worst-case analysis reflect conservative estimates of source emissions and emission release characteristics (assuming consumption of all cell material in a container, ignoring the deposition or adsorption of compounds, the reactivity and solubility of compounds, fire induced mixing, and plume effective fire based plume rise), available meteorological data near the project site, and the use of currently approved air quality models. There are limits to the use of these available tools for such an analysis, as described herein. However, the combined use of the AERMOD dispersion model and the health impact calculations required by OEHHA and AVAQMD tend to over-predict potential impacts such that they produce conservative (i.e., health-protective) results. Accordingly, the health impacts would be less than the less than significant impacts described in this assessment. Furthermore, the assumption of one unit undergoing a complete thermal runaway is highly unlikely based on the UL9540A testing and safety systems in place.

As such, the proposed Project would not result in any significant public health or air quality impacts to proximate sensitive receptors.

2.2.3 Ventilation Design

The battery container intakes air from the front / top side and expels it from the top, as shown below.

Figure 2-5 Schematic diagram of ventilation

2.2.2 Mechanical Parameters

Dimensions

The external dimensions of the container are shown in the figure.

Figure 2-3 Dimensions of battery container

Height =	2896 mm
	2.896 m
Cabinet width =	6058 mm
Per panel estimate =	1211.6 mm
2x vent diameter =	605.8 mm
Vent Diameter =	300.09 mm
Vents per container =	12

Prairie Song BESS Project
Thermal Runaway Analysis Results

Table 1. Max Emission Rates for Project - Entire Unit Thermal Runaway

Max Rates	Propane	Butane	Carbon Monoxide	Hydrogen fluoride	Hydrogen Cyanide	Hydrochloric Acid
Hourly Max, g/s	0.09	0.03	2.38	0.17	0.05	0.05
Hourly Max lbs/hr	0.69	0.26	18.92	1.38	0.37	0.37

Table 2. LSFT AERMOD Impact X/Q, (µg/m³)/(g/s)

MEIR	Receptor at 10 m downwind	Receptor at 20 m downwind
Max 1-Hour		
134.29	14,171.75	6,493.89
Distance Scaler (MEIR divided by downwind receptor concentration)	0.01	0.02

Note: These concentrations are based on the AERMOD Results Summary Report for wind between 0 and 2.7 meters per second, consistent with the LSFT sampling conditions.

Table 3. Average Concentration For Project from LSFT (ppm)

Analysis	Benzene	Formaldehyde	Toluene	Sulfur Dioxide	Nitrogen Dioxide
From LSFT 10 meters	0.12	0.15	0.17	0.02	0.03
Scaled to MEIR (91 meters)	0.001	0.001	0.002	0.0001	0.0003
From LSFT 20 meters	0.17	0.25	0.19	0.02	0.04
Scaled to MEIR (91 meters)	0.004	0.005	0.004	0.0003	0.0007
Maximum Scaled (10 or 20 meters)	0.004	0.005	0.004	0.0003	0.0007
Maximum Scaled (10 or 20 meters µg/m³)	11.4	6.4	14.66	0.81	1.39

Table 4. AERMOD Maximum Impact X/Q, (µg/m³)/(g/s)

MEIR	
Max 1-Hour	Max 8-Hour
872.12	661.22

Note: These concentrations are based on the AERMOD Results Summary Report

Table 5. Project Contribution Concentrations (µg/m3)

Pollutant	CAS No.	Hr. Max (g/s)	X/Q (µg/m3)/(g/s)	Project Concentration (µg/m3)	REL (µg/m3)	AEGL (µg/m3)	Project Exceed REL or AEGL?	Acute Hazard Quotient	Health Endpoint

*** MODELOPTs: RegDEFAULT CONC ELEV RURAL ADJ_U* BUOYLINE

*** MODEL SETUP OPTIONS SUMMARY

** Model Options Selected:

- * Model Uses Regulatory DEFAULT Options
- * Model Is Setup For Calculation of Average CONCentration Values.
- * NO GAS DEPOSITION Data Provided.
- * NO PARTICLE DEPOSITION Data Provided.
- * Model Uses NO DRY DEPLETION. DDPLETE = F
- * Model Uses NO WET DEPLETION. WETDPLT = F
- * Stack-tip Downwash.
- * Model Accounts for ELEVated Terrain Effects.
- * Use Calms Processing Routine.
- * Use Missing Data Processing Routine.
- * No Exponential Decay.
- * Model Uses RURAL Dispersion Only.
- * ADJ_U* - Use ADJ_U* option for SBL in AERMET
- * CCVR_Sub - Meteorological data includes CCVR substitutions
- * TEMP_Sub - Meteorological data includes TEMP substitutions
- * Model Assumes No FLAGPOLE Receptor Heights.
- * The User Specified a Pollutant Type of: ALL

**Model Calculates 2 Short Term Average(s) of: 1-HR 8-HR

**This Run Includes: 1 Source(s); 1 Source Group(s); and 34698
Receptor(s)

with: 0 POINT(s), including
0 POINTCAP(s) and 0 POINTHOR(s)
and: 0 VOLUME source(s)
and: 0 AREA type source(s)
and: 0 LINE source(s)
and: 0 RLINE/RLINEXT source(s)
and: 0 OPENPIT source(s)
and: 1 BUOYANT LINE source(s) with a total of 1 line(s)
and: 0 SWPOINT source(s)

**Model Set To Continue RUNning After the Setup Testing.
