Sacramento, CA 95814-5512

**Re: Docket No. 15-RETI-02 – MID Comments in Response to the Renewable Energy Transmission Initiative 2.0 Plenary Group Meeting, March 16, 2016**

The Modesto Irrigation District (“MID”) appreciates the opportunity to offer comments in response to the March 16, 2016 Meeting held by the Plenary Group for the Renewable Energy Transmission Initiative (“RETI”) 2.0 process.

MID is an irrigation district, organized and operated under the laws of the State of California, which undertakes both electric and water operations. With regard to its electric operations, MID owns and operates facilities for the generation, transmission, distribution, purchase, and sale of electric power and energy at wholesale and retail. MID is a fully integrated, fully resourced utility. MID has commented previously in this stakeholder process, both through oral comments at the meetings and conferences and through written comments.

In connection with the most recent Plenary Group meeting, MID asks that the RETI process examine the use and costs of existing trunklines or similar electric transmission facilities to ensure that they are factored into the costs of bringing remote, renewable resources, such as New Mexico or Wyoming wind, into California. In an effort to maximize the efficient utilization of existing transmission infrastructure, transmission to access renewable energy resources in the Rocky Mountain/Plains regions perhaps need only be built to an intermediary point, for example, to an existing collection point in Utah, Arizona or Nevada. A determination as to whether or not existing transmission assets provide sufficient transfer capability to transmit the renewable energy generation the remainder of the way into California should be considered in the cost impact exploration process. The RETI process should consider the availability of such transmission, weighed against the costs and outcomes of not using such transmission should new transmission construction be chosen in lieu of using such facilities.

As MID explained at the March 16 Meeting, the existing renewable energy resource procurement process provides a lot of lessons learned and market sensitivities when it comes to obtaining resources that are cost effective and meet the needs of the electric utilities. One of the data inputs that exists and that can be used for the methodologies applied in the RETI process include using actual data points, such as from Requests for Offers (“RFOs”) made public that specify prices requested for renewable energy resources. For example, the City of Riverside negotiated a 20-year power sale agreement with a supplier at a fixed price of \$53.75/MWh in the summer of 2015<sup>1</sup>; this particular RFO for solar resources yielded a price lower than what appears to be included in cost assumptions for Power Purchase Agreements in the RETI process.<sup>2</sup> While any given RFO may not be successful in terms of the price ultimately agreed to for the resource, the RFO process does provide a real world indicator of the renewable resource marketplace supply and demand that can be utilized in a sensitivity analysis when comparing the projected leveled costs of renewable energy that are developed by the California Energy Commission and RETI 2.0 process against the price at which utilities are willing to acquire resources.

The RETI 2.0 process should also account for projects designed to address reliability issues. Reliability-driven projects are one class of projects that are part of the California Independent System Operator Corporation (“CAISO”) Transmission Planning Process. The CAISO has also accounted for the use of reliability-driven projects in its Straw Proposal<sup>3</sup> as to Transmission Access Charge (“TAC”) options under a regional grid operator footprint. Part of the CAISO’s proposal would determine how the costs of regional projects that are driven by reliability needs are allocated across sub-regions.<sup>4</sup> While RETI 2.0 focuses on transmission necessary to reach resources needed to meet the state renewable energy goals, the anticipated construction of transmission for reliability needs may affect the boundaries of renewable energy zones identified in the RETI 2.0 process. Transmission constructed for reliability needs may also impact cost considerations, in that transmission may not be necessary to the same degree for policy or renewable energy needs if it is already being constructed for reliability needs. Such reliability-driven transmission may counsel in favor of alternative configurations for the transmission projects being discussed as part of the RETI 2.0 process.

Lastly, there appears to be no emphasis on the potential impacts from the deployment of energy storage technology. This is not a major part of the evaluative criteria that utilities use when evaluating renewable energy resources, but it could have a larger impact in the future as additional renewable energy resources are implemented.
