1.0 INTRODUCTION

Bloom Biological, Incorporated (BBI) was retained by Aspen Environmental Group (Aspen) to conduct winter surveys for Golden Eagle (Aquila chrysaetos) for the proposed Desert Harvest Solar Project (project site) located in unincorporated Riverside County, California. The Golden Eagle is an uncommon permanent resident and migrant throughout most of California’s foothills, mountains, sage-juniper flats and deserts (CDFG 2008), and is protected under the federal Bald and Golden Eagle Protection Act and by the California Department of Fish & Game as a Fully Protected Species. Golden Eagle status studies completed as recently as 1989 suggested a stable population for much of the western United States (Harlow and Bloom 1989); however, recent evidence suggests that eagle numbers in the western United States are now declining. As a result, the U.S. Fish and Wildlife Service (Service) is recommending focused surveys in nesting habitat within ten miles of proposed projects that might cause anthropogenic disturbances to eagles. Future recommendations regarding Golden Eagle wintering and migratory habitat use are being developed.

The winter survey described in this report will assist BBI and Aspen in further developing impact avoidance and management guidelines for this species in the project area. This report discusses BBI’s survey methods, results and recommendations.

2.0 STUDY AREA DESCRIPTION

The project site is comprised of approximately 1,205 acres (488 hectares) of open desert in east-central Riverside County, California (see Figure 1). The site is located on all or portions of Public Land Survey Sections 26 and 27 of Township 4 South, Range 15 East of the US Geological Survey’s (USGS) 7.5-minute Victory Pass quadrangle and Section 25 of Township 4 South, Range 15 East of the East of Victory Pass quadrangle. Terrain on the site is flat, with elevations ranging from 584 to 675 feet (178 to 206 meters) above mean sea level (amsl), with a mean elevation of 623 feet (190 meters) amsl. The project site is accessed via County Route R2, which heads north from Desert Center – Rice Road just north of Interstate 10.

The study area for this survey includes the project site and all lands within a ten mile radius of the project site (Exhibits 1 and 2). For the purpose of this document, this region will be referred to as the “study area”. The study area is comprised of approximately 247,160 acres (100,022 hectares) located on all or portions of the USGS 7.5-minute Placer Canyon, Pinto Wells, Coxcomb Mountains, West of Palen Pass, Buzzard Spring, Victory Pass, East of Victory Pass, Palen Lake, Hayfield Spring, Desert Center, Corn Spring and Sidewinder Well quadrangles. Terrain in the study area varies from flat to mountainous with elevations ranging from 423 to 3,983 feet (129 to 1,214 meters) amsl, with a mean elevation of 1,204 feet (367 meters) amsl. Significant Holland (1986) land cover types in the study area are Agriculture, Alkali Playa, Blackbush Scrub, Desert Dry Wash Woodland, Mojave Creosote Bush Scrub, Mojave Mixed Woody Scrub, Mojavean Pinyon and Juniper Woodlands, Sonoran Creosote Bush Scrub and Sonoran Desert Mixed Scrub (Exhibit 3). Potential locations for Golden Eagle nesting in the study area include the Eagle Mountains to the west, Coxcomb Mountains to the north, Palen Mountains to the east, and Chuckwalla Mountains to the south. Golden Eagles are also known to build nests on electrical towers, the majority of which run east-west in the southern end of the study area.

---

1 Elevation values derived from GRASS GIS version 6.4 using module r.univar on a US Geological Survey 1/3-minute digital elevation model.

2 Land cover types and extents based on GAP Analysis Project data and determined via a PostGIS/PostgresSQL spatial query.

3.0 METHODS

BBI biologists conducted eight surveys from December 22, 2011 to February 7, 2012. The primary objective of the surveys was to document the locations, if any, of Golden Eagles and Golden Eagle nests observed in the study area. The secondary objective was to document the location of other raptor and corvid nests. BBI biologists documented all other biological resources of potential permitting significance. Surveys were generally completed from sunrise to mid-afternoon or near sunset. Weather conditions varied throughout but were generally seasonable with no rain or other significant weather events that could adversely affect observations. Much of the study area was covered via vehicle on both improved and unimproved roads. Foot travel was necessary for close inspection of nests and viewing of terrain when a vehicle approach did not allow an appropriate vantage point. All findings of biological significance (e.g., nests, sensitive species) were documented with a GPS waypoint and photograph where feasible.

### 4.0 RESULTS

#### 4.1 General Biological Conditions

A total of 41 bird, six mammal and two reptile species were observed during BBI's surveys. A comprehensive list of these species is provided in the Faunal Compendium which is attached as Appendix A. Other than Golden Eagle, the most significant resource observation during BBI's surveys was that of a shell fragment of a juvenile or immature Desert Tortoise (*Gopherus agassizi*) near the southwest edge of the study area on January 20, 2012 (point 111, Exhibit 4). The Desert Tortoise is listed as Threatened with Critical Habitat designated under the Federal Endangered Species Act. The project site is located approximately 1.25 miles northeast of the limits of the Chuckwalla Unit of Desert Tortoise Critical Habitat (Service 1994, Figure 2).

*Figure 2. Desert Tortoise Critical Habitat Relative to the Project Site and Study area.*

Probable migratory corridors, at least for Turkey Vultures (*Cathartes aura*), were detected in the west end of the study area (points 155 and 156, Exhibit 4) by BBI on February 1, 2012. In BBI’s project database, biologist Karly Moore noted:

Note: Additional photographs available upon request.
Over the course of the day groups of turkey vultures were seen migrating WNW over Eagle Mountain. The first group of 80 turkey vultures were seen thermaling low below the ridgetop along the slope over by the aqueduct substation (643952, 3742418). This was the area the vultures were seen crossing a few weeks prior. Later in the day 136 turkey vultures were seen passing a little more to the west (639895, 3734170) traveling low and even into the draw/canyon by the old inactive golden eagle nest in the boulder.

One California Species of Special Concern, a Long-eared Owl (Asio otus) was flushed from a wash on the south side of the study area on January 10, 2012.

A variety of large bird nests were also documented. These will be described in the following section.

4.2 Golden Eagles & Other Raptors

Golden Eagles are present in the area, but it is uncertain whether they are currently regularly using the proposed project’s study area. On January 10, 2012, one adult Golden Eagle was observed soaring near the southeastern edge of the study area just north of Interstate 10 (point 108, Exhibit 4). The eagle was thermaling with approximately 80 Common Ravens (Corvus corax) and three Turkey Vultures. No other Golden Eagles were detected during BBI’s surveys.

Eight Golden Eagle nests or probable Golden Eagle nests were detected by BBI during the surveys. All were located on utility poles. None of the nests appeared to be recently active. All of the nest locations identified by BBI are shown on Exhibit 4 and in Table 2 below. Eight additional Golden Eagle nest locations from 2010 were provided by the Bureau of Land Management. At least one of these nests was active in 2010. The nests are shown on Exhibit 4 and in Table 3 below.

Uncommon raptor species detected during the surveys include Prairie Falcon (Falco mexicanus) with three observed on January 20, 2012 and two observed on February 7, 2012, and the aforementioned Long-eared Owl observed on January 10, 2012. Common raptor species detected during BBI’s surveys were Sharp-shinned Hawk (Accipiter striatus), Cooper’s Hawk (Accipiter cooperi), Red-tailed Hawk (Buteo jamaicensis), and American Kestrel (Falco sparverius). Red-tailed Hawk was the only raptor species, other than Golden Eagle, for which nest locations were detected during BBI surveys. Nests were observed at points 46, 60, and 105 (Exhibit 4 and Table 2).

Table 2. Nest Locations & Descriptions

The following table shows all large bird nests detected during BBI’s surveys. These nests are also depicted with their coordinates on Exhibit 4.

5.0 CONCLUSIONS & DISCUSSION

While there is currently an effort to build a larger “sustainable” energy infrastructure in the United States and abroad with expected fewer overall environmental effects than the existing hydrocarbon-based infrastructure, conservation biologists are still in the process of establishing what effects alternative
energy plants might have on the environment at the local level. It is well-established that Golden Eagles and other raptors are vulnerable to mortality through collision with wind turbines (Orloff and Flannery 1992, PBGR 1997, Madders and Walker 2002). For solar facilities, potential effects on wildlife are in the early stages of investigation, but it is expected that raptors and other species could suffer adverse effects due to reduced foraging habitat, and potentially, a reduction in the prey base also caused by habitat loss for prey species. Specifically, BBI has identified the following potential adverse effects on Golden Eagles attributed to solar projects:

- **Direct Mortality** - Long-term surveys of Golden Eagle populations have shown declines in nesting populations throughout the western United States (Kochert and Steenhof 2002). Franson et al. (1995) found that humans cause >70% of recorded deaths, with the leading causes being accidental trauma (collisions with vehicles, power lines, or other structures, 27%), electrocution (25%), gunshot (15%), and poisoning (6%). Lead poisoning in California has also been identified as an important mortality factor with > 30% of a population having elevated levels (Bloom et al. 1989, Pattee et al. 1990).

Electrocution is a particular risk potentially posed by infrastructure associated with many solar projects. Golden Eagles are vulnerable to electrocution when landing on power poles, with the risk increasing when inclement weather hampers flight or when wet feathers increase conductivity (Avian Power Line Interaction Committee 1996). Harness and Wilson (2001) reported that ≥272 Golden Eagle electrocution deaths occurred in western North America from 1986 to 1996. Poles with cross arms diagonal or parallel to prevailing winds are most lethal (Benson 1981, Harness and Wilson 2001).

For this proposed project, the specifics of the proposed electrical infrastructure are unknown to BBI at this time. BBI recommends that electrocution risk be minimized through the use of bird-safe pole designs.

- **Nest Failures** - Golden Eagles may desert nests in early incubation if disturbed by humans (Thelander 1974), and potential desertion may not be noticed early through behavioral cues as Golden Eagles are not aggressive toward humans in the nest vicinity and will simply leave and not return to the area for hours (Camenzind 1969), if ever. While data collected in this survey suggest that the proposed project is unlikely to cause such an effect directly, project implementation could contribute to cumulative or growth-inducing impacts, ultimately causing additional anthropogenic disturbance in the area over time.

- **Indirect Mortality** – Management of healthy eagle populations requires maintaining prey habitat in foraging areas (Kochert et al. 2002), as the availability of food and nesting sites is the primary factor determining nesting density of Golden Eagles (Hunt et al. 1995), and reproductive rates of Golden Eagles often fluctuate with prey densities (Smith and Murphy 1979, Tjernberg 1983, Bates and Moretti 1994, Steenhof et al. 1997, McIntyre and Adams 1999). In southwestern Idaho, Marzluff et al. (1997) have found that behavior and demography of Golden Eagles are closely associated with the abundance of Black-tailed Jackrabbits (*Lepus californicus*), which are themselves dependent on stands of sagebrush/rabbitbrush interspersed with grassland (Knick and Dyer 1997). Bloom and Hawks (1982), working in the Great Basin Desert of northeast California and northwest Nevada, found that 91% of the biomass and 85% of the frequency of prey found in nests were attributed to lagomorphs. Patch sizes of this habitat were found to be an essential feature of Golden Eagle home ranges (Marzluff et al. 1997).

In the study area for this proposed project, BBI biologists stated that there was “a notable absence of prey items on the site”. Indeed, Black-tailed Jackrabbits were only observed in small numbers during the surveys, with one on January 6, two on January 10, one on January 20 and
three on February 1, 2012. While Golden Eagles are capable of killing large prey such as cranes, wild ungulates, and domestic livestock, smaller game such as rabbits, hares, ground squirrels, and prairie dogs are most important (Bloom and Hawks 1982, Olendorff 1976). As jackrabbit population levels are cyclical, it is unclear if the relatively low number of jackrabbits detected during the surveys were an indication of poor habitat quality or reflect numbers indicative of the low end of population fluctuation.

Golden Eagles typically reach sexual maturity, form territories and begin nesting at four years of age. Pairs generally stay within the limits of their territory, which can measure 20–30 square kilometers, and within that territory can have as many as 14 nests (Bloom pers. obs.) which a pair maintains and repairs as part of its courtship ritual. Over the course of a decade several of these nests will be used and will produce young, others may only be maintained with the periodic addition of fresh sticks. Most alternate nests are important in the successful reproduction of a pair of eagles. Pairs commonly refrain from laying eggs in some years, particularly when prey is scarce.

Given the presence of Golden Eagles and at least eight confirmed or probable Golden Eagle nests in the study area, but the lack of any indication of recent nest activity, it is the opinion of BBI that although Golden Eagles are present in the study area, they may not have recently nested within it because of low prey levels. BBI recommends that winter and springs surveys for Golden Eagle be conducted yearly until project construction is completed.
