Socioeconomics staff has determined that the population in the six mile buffer does not constitute an environmental justice population as defined by “Environmental Justice: Guidance under the National Environmental Policy Act” and would not trigger further scrutiny for purposes of an environmental justice analysis.

INTRODUCTION

On December 15, 2010, the Energy Commission approved the 500-megawatt (MW) Palen Solar Power Project (PSPP) for construction and operation. On December 17, 2012, Palen Solar Holdings, Inc. (project owner) filed a petition to modify the PSPP and requested that the project name be changed to Palen Solar Electric Generating System (PSEGS). The proposed PSEGS contains several modifications, the most notable being the change in solar thermal technology of power generation, from parabolic trough technology to solar tower technology. All proposed modifications are described in the **PROJECT DESCRIPTION** section of this Final Staff Assessment (FSA).

This analysis addresses potential impacts to soil and water resources through the construction and operation of the modified PSEGS project. Where impacts are found to be the same or less than impacts of the approved PSPP project, staff applied the existing Conditions of Certification, as contained in the Commission Decision dated December 15, 2010 (CEC 2010f), to reduce those impacts to less than significant.[1] Aspects of the modified project that are new or substantially different from the approved project have been identified and examined for potential impacts. To reduce these impacts to less than significant, staff recommends new conditions of certification. In this analysis, the term “approved project” refers to the PSPP and the term “modified project” refers to the proposed modified PSEGS.

METHODOLOGY AND THRESHOLDS FOR DETERMINING ENVIRONMENTAL CONSEQUENCES

Significance criteria are based on those listed in CEQA Appendix G. Soil and water resources impacts would be significant if the project would:

- violate any water quality standards or waste discharge requirements;
- substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the

[1] The analysis presented in the PSPP Revised Staff Assessment (CEC 2010c) has been included in the text of this FSA, where applicable, for the reader's reference.

local groundwater table level (e.g., the production rate of pre-existing nearby wells would drop to a level which would not support existing land uses or planned uses for which permits have been granted);

- substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner which would result in substantial erosion or siltation onsite or offsite;
- substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner which would result in flooding onsite or offsite;
- create or contribute runoff water that would exceed the capacity of existing or planned storm water drainage systems or provide substantial additional sources of polluted runoff;
- otherwise substantially degrade surface water or groundwater quality;
- place structures within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood hazard delineation map;
- place structures within a 100-year flood hazard area that would impede or redirect flood flows;
- expose people or structures to a significant risk of loss, injury or death involving flooding, including flooding as a result of the failure of a levee or dam;
- result in substantial soil erosion or the loss of topsoil;
- have impacts that are individually limited, but cumulatively considerable ("Cumulatively considerable" means that the incremental effects of a project are considerable when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects); or
- have environmental effects which will cause substantial adverse effects on human beings, either directly or indirectly.

Although the CEQA Guidelines provide a checklist of suggested issues that should be addressed in an environmental document, neither the CEQA statute nor the CEQA guidelines prescribe thresholds of significance or particular methodologies for performing an impact analysis. This is left to lead agency judgment and discretion, based on factual data and guidance from regulatory agencies and other sources where available and applicable. Staff assessed whether the PSEGS project would comply with the LORS and policies described in **Soil & Water Resources Table 2** and whether there would be a significant impact under the CEQA. Where a potentially significant impact was identified, staff proposed mitigation to ensure the impacts would be less than significant.

LAWS, ORDINANCES, REGULATIONS, AND STANDARDS (LORS)

Soil & Water Resources Table 2
Laws, Ordinances, Regulations, and Standards (LORS) and Policies

Applicable LORS	Description
Federal	
Clean Water Act of 1977 (Including 1987 Amendments) Sections 401, 402 and 404	The primary objective of the Clean Water Act (CWA) is to restore and maintain the chemical, physical, and biological integrity of the Nation's surface waters. Section 401: Requires certification that the proposed project is in compliance with established water quality standards. Section 402: Direct and indirect discharges and storm water discharges into waters of the United States must be made pursuant to a National Pollutant Discharge Elimination System (NPDES) permit. Section 404: Activities resulting in the dredging or filling of jurisdictional waters of the U.S. require authorization under a Section 404 permit issued by the U.S. Army Corp of Engineers (USACE).
State	
State of California Constitution Article X, Section 2	Prohibits the waste or unreasonable use of water, regulates the method of use and method of diversion of water and requires all water users to conserve and reuse available water supplies to the maximum extent possible.
SWRCB Order 2009-0009-DWQ	The State Water Resources Control Board (SWRCB) regulates storm water discharges associated with construction affecting areas greater than or equal to 1 acre to protect state waters. Under Order 2009-0009-DWQ, the SWRCB has issued a NPDES General Permit for storm water discharges associated with construction activity.
SWRCB Order 97-03-DWQ	The SWRCB regulates storm water discharges associated with several types of facilities, including steam electric generating facilities. Under Order 97-03-DWQ, the SWRCB has issued a NPDES General Permit for storm water discharges associated with industrial activity.
California Water Code Section 461	Stipulates that the primary interest of the people of the State of California is the conservation of all available water resources and requires the maximum reuse of reclaimed water as an offset to using potable resources.
California Water Code Section 1200 "Water Rights"	California's water rights law is a hybrid system in that the use of certain types of water requires a permit from the SWRCB, while other types of uses are governed by common law.
The Porter-Cologne Water Quality Control Act of 1967, California Water Code Section 13000 et seq.	Requires the SWRCB and the nine Regional Water Quality Control Boards (RWQCBs) to adopt water quality standards to protect State waters. Those standards include the identification of beneficial uses, narrative and numerical water quality criteria, and implementation procedures.
California Code of Regulations Title 22, Article 3, Sections 64400.80 through 64445	This section requires monitoring for potable water wells, defined as non-transient, non-community water systems (serving 25 people or more for more than six months). Regulated wells must be sampled for bacteriological quality once a month and the results submitted to the California Department of Public Health (CDPH).
California Code of Regulations Title 23, Division 3, Chapter 9	This chapter requires the Colorado River Basin RWQCB (CRBRWQCB) to issue a report of waste discharge for discharges of waste to land pursuant to the Water Code.

Applicable LORS	Description
California Code of Regulations Title 23, Division 3, Chapter 15	Regulates all discharges of hazardous waste to land that may affect water quality.
State Policies and Guidance	
SWRCB Res. 68-16	Anti-Degradation Policy: This policy restricts degradation of surface and ground waters. In particular, this policy protects water bodies where existing quality is higher than necessary for the protection of beneficial uses.
SWRCB Res. 75-58	Power Plant Cooling Water Policy: The purpose of the policy is to provide consistent statewide water quality principles and guidance for adoption of discharge requirements, and implementation actions for power plants that depend on inland waters for cooling.
SWRCB Res. 77-01	Water Reclamation Policy: Under this policy, the SWRCB and CRBRWQCBs shall encourage reclamation and reuse of water in water-short areas.
SWRCB Res. 92-49	Policies and Procedures for Investigations and Clean-up and Abatement of Discharges Under CWC Section 13304: Under this policy, clean-up and abatement actions are to implement applicable provisions of Title 23 CCR Chapter 15, to the extent feasible.
SWRCB Res. 2009-0011	Water Quality Control Policy for Recycled Water: The purpose of this Policy is to increase the use of recycled water from municipal wastewater sources that meets the definition in CWC Section 13050(n), in a manner that implements state and Federal water quality laws.
Public Resources Code Section 25300 et. seq.	The Energy Commission adopted a policy stating they would approve the use of “fresh inland” water for cooling purposes by power plants only where alternative water supply sources and alternative cooling technologies are shown to be “environmentally undesirable” or “economically unsound.”
State Water Policy	The Energy Commission has five authoritative sources for statements of policy relating to water use in California applicable to power plants. They are the California Constitution, the Warren-Alquist Act, the Commission’s restatement of the state’s water policy in the 2003 Integrated Energy Policy Report (“IEPR”), the State Water Resources Control Board resolutions (in particular Resolutions 75-58 and 88-63), and a letter from the Board to the Energy Commission interpreting Resolutions 75-58 and 88-63 [collectively referred to as the state’s water policies - see Genesis Solar Project (09-AFC-08)].
Local	
Riverside County Ordinance Code, Title 13, Chapter 13.20	Establishes requirements to construct and operate groundwater wells.
Riverside County Ordinance Code, Title 8, Chapter 8.124	Establishes requirements to construct and operate sanitary wastewater disposal systems.
Riverside County Title 15 Chapter 15.24 Uniform Plumbing Code	Adopts by reference the California Plumbing Code, including the appendix and standards, for the installation and inspection of plumbing systems as a means of promoting the public's health, safety and welfare.

Applicable LORS	Description
Riverside County Title 15 Chapter 15.80 Regulating Flood Hazard Areas and Implementing the National Flood Insurance Program	This ordinance was developed to comply with Title 44 CFR Part 65 regarding requirements for the identification and mapping of areas identified as Federal Emergency Management Agency (FEMA) Special Flood Hazard Areas.

PROPOSED MODIFIED PROJECT

Characteristics of the modified project that have the potential to impact soil and water resources differently than the approved project are shown in **Soil & Water Resources Table 3**.

Soil & Water Resources Table 3
PSPP vs. PSEGS Features Impacting Soil and Water Resources

Feature	PSEGS – Modified Project (500 MW)	PSPP – Approved Project (500 MW)
Solar technology	solar tower - two adjacent solar fields, each consisting of a power block and approximately 85,000 heliostats for heating a receiver on top of a 750 foot tall solar power tower	parabolic trough – two adjacent solar fields, each consisting of a power block and rows of parabolic mirrors for heating heat transfer fluid (HTF)
Project footprint	approximately 3,794 acres	approximately 4,365 acres
Water use during construction	400 acre-feet per year (total of 1,130 acre-feet)	1,917 acre-feet per year (total of 5,750 acre-feet)
Water use during operations	up to 201 acre-feet per year	up to 300 acre-feet per year
Evaporation ponds	two 2-acre ponds	four 4-acre ponds
Land Treatment Units (LTUs)	not required	required to treat HTF-contaminated soils
Solar field grading	maintaining existing vegetation to the extent possible; limited grading for roads, power blocks, and common facilities area (total earthwork approximately 213,000 cubic yards)	grading of entire solar fields to create flat, uniform topography and elimination of all vegetation (total earthwork approximately 4,500,000 cubic yards)
Storm water drainage control	maintain natural drainage patterns for the majority of the site; diversion channels bypass storm water runoff around power blocks and common facilities area	eliminate all onsite natural drainage and construct three large drainage control channels to bypass all offsite storm water runoff around the solar fields
Common facilities area	a common facilities area of approximately 15 acres located in the southwestern corner of the site containing: main office building, warehouse and maintenance buildings, and evaporation ponds	a common facilities area of approximately 50 acres located in a southwestern edge of the site containing: main office building, warehouse and maintenance buildings, and laydown area
Temporary construction laydown area	203 acres located in the southwestern portion of the site immediately north of the common facilities area	various locations around the site, including the common facilities area and near each power block
Length of construction	33 months	39 months

Feature	PSEGS – Modified Project (500 MW)	PSPP – Approved Project (500 MW)
Off-site linear facilities	The modified project includes a slight re-routing of the generation tie-line and the redundant telecommunication line near the western end of the approved route, around the newly constructed Red Bluff Substation. The modified project also includes a natural gas pipeline from a new extension of the existing Southern California Gas (SoCal Gas) distribution system.	

Source: Palen 2012a §5.2, CEC 2010f

Refer to the **PROJECT DESCRIPTION** section of this FSA for more information on PSEGS major features. **Project Description Figure 5** shows the location of the proposed modified project with respect to the approved project, as well as the offsite linear facilities. Additional information relevant to the soil and water resources analysis is summarized below. For a complete detailed description of the proposed modified project, refer to the Petition for Amendment (Palen 2012a) and the project owner's related supplemental material.

PROJECT CONSTRUCTION

Construction of the approved project was to be accomplished in two, overlapping phases, requiring 39 months for completion, with completion of the west solar field within six months after the east solar field. For the modified project, the two phases would be constructed over a similar time frame, with construction of Solar Plant 1 beginning only a few months prior to that for Solar Plant 2. Commercial operation for both plants is expected to begin at the same time[2]. The entire construction period would be 33 months versus the 39 for the approved project (Palen 2013h §5).

Soil Erosion and Storm Water Control

During construction, portions of the PSEGS site would be graded, including portions along the ephemeral washes. Grading is not intended to level the site, but rather to prepare the site for installation of the heliostats and ease future maintenance activities. As such, the drainages would remain, to the extent feasible, and natural drainage waters are expected to continue to flow in and through these ephemeral washes. Any grading required would be designed to maintain existing drainage pathways, where possible (Palen 2013e §3.4).

Power Plant Sites

Major items at each PSEGS solar plant would include a steam turbine system, an air-cooled steam condenser system, and a 750-foot-tall solar power tower topped with a solar receiver steam generator (SRSG). Other associated items include various raw water/wastewater treatment facilities with water storage tanks, auxiliary boilers, mirror washing related equipment, a wet surface air cooler (WSAC), a gas metering set, and a plant services building with parking. Heavy to medium grading would be performed within each plant’s solar power tower and power block areas. The earthwork within the power blocks would be excavated and compacted to the recommendations of the final geotechnical report. The deepest excavations would occur for foundations and sumps.

[2] The first construction phase would include construction of the generation tie-line, access road, common facilities area, common facilities, temporary construction laydown area, both power blocks including laydown area, and a portion of Solar Field 2. The second construction phase would include the construction of Solar Field 1 and the remainder of Solar Field 2 (Palen 2013a).

Within each of these individual areas, earthwork cuts and fills would be balanced to the greatest degree possible (Palen 2012a §§2.2, 2.13).

Prior to construction, the project owner would prepare a Storm Water Pollution Prevention Plan (SWPPP) to control storm water and soil erosion during the facility's construction using best management practices (BMPs).[3] To redirect storm water flow around these facilities, diversion channels, bypass channels, or drainage swales would be used. Stone filters and check dams would be placed strategically, as needed, throughout the project site to provide areas for sediment deposition and to promote the sheet flow of storm water prior to leaving the project site boundary. Native materials (rock and gravel) would be used where available for the construction of the stone filter and check dams. Stone filters and check dams are not intended to alter drainage patterns, but to minimize soil erosion and promote sheet flow (Palen 2012a §2.13).

Permanent diversion channels would be built around both Solar Plant 1 and Solar Plant 2 power blocks during the early stages of power plant construction to provide storm water management of the power block area during construction activities. These channels would be designed with a minimum ground surface slope of 0.5 percent to allow positive, puddle-free drainage. To reduce erosion, storm drainage channels may be lined with a nonerodible material such as compacted riprap, geosynthetic matting, or engineered vegetation (Palen 2013e §3.4.3).

Solar Fields – Heliostats

The approved project would have required extensive grading to maintain a consistent grade for interconnecting piping and three major drainage channels to manage storm water around the entire solar field. The modified project would instead require much less grading because the heliostat technology does not require an entirely flat surface (Palen 2012a §2.13).

The modified project would be designed to provide the minimum requirements for access of installation equipment and materials during site construction and operations. Most of the natural drainage features would be maintained and any grading required would be designed to promote sheet flow where possible. Areas disturbed by grading and other ground disturbance would be protected from erosion by implementation of appropriate BMPs (Palen 2012a §2.13).

Solar field development would maintain unobstructed sheet flow, with storm water mostly traveling in existing natural contours and flowpaths. Relatively small rock filters and local diversion berms through the heliostat fields may be installed as required to discourage water from concentrating and to maintain sheet flow. Mowing of vegetation, rather than removal, would allow for clearance for heliostat function while leaving soil surface and root structures intact (Palen 2013e §4.4).

---

[3] Storm water and soil erosion BMPs are methods that have been determined to be the most effective, practical means of preventing or reducing pollution from nonpoint sources. BMPs can be classified as "structural" (i.e., devices installed or constructed on a site) or "non-structural" (procedures, such as modified landscaping practices). There are a variety of BMPs available, depending on pollutant removal capabilities. (See California Stormwater BMP Handbook at www.casqa.org.)

Each solar field would consist of approximately 85,000 heliostats - elevated mirrors each with a total reflecting surface of 204.7 square feet. Each heliostat assembly would be mounted on a single support pylon and guided by a computer-programmed aiming control system to track the movement of the sun. Communication between the heliostats and the operations center would be done via surface-mounted anchored cable or wireless remote system (Palen 2012a § 2.2).

The siting of pylons would be guided by global positioning system (GPS) technology. Installation of the heliostat assemblies would use vibratory technology to insert the pylons into the ground and a rough terrain crane able to mount heliostat assemblies on several pylons before moving to the next location. Depths are not expected to be greater than 12 feet. Vegetation clearing, grubbing,[4] and contour smoothing in the heliostat fields would occur where necessary to allow for equipment access and storm water management. In areas where these activities are not required for access or construction, the vegetation would not be removed, but would be mowed (if needed) to a height of approximately 12 to 18 inches (Palen 2012a §2.13).

Solar Fields – Roads

PSEGS would contain six types of roads (Palen 2012a Appendix 2-D, Palen 2013a Appendix A, Palen 2013e) as shown on **Soil & Water Resources Figure 1**:

- 24-ft wide asphaltic paved road provides access to the site from Interstate 10
- 20-ft wide asphaltic paved roads located within the solar field connect the power blocks/towers to each other
- 20-ft wide dirt (aggregate base) road located at the boundary of the two solar fields from where the 20-ft paved road ends to the northeast boundary of the site.
- 12-ft wide asphaltic paved roads located around the perimeter of the common area facilities
- 12-ft wide dirt (aggregate base) roads located around the perimeter of the site, around the perimeter of the power blocks, and spike access from power blocks to the site perimeter
- 10-ft wide circular dirt (cleared and smoothed) roads placed approximately 152 feet apart located concentrically around the power blocks areas provide maintenance access to the heliostats

Most of the natural drainage features would be maintained and any grading required would be designed to promote sheet flow where possible (Palen 2013e §3.4).

[4] Grubbing of vegetation includes the removal of any remaining roots or stumps after cutting vegetation to clear land.

Common Area

A 15-acre common facilities area would be established in the southwestern corner of the site to accommodate an administration building, warehouse, and maintenance complex; evaporation ponds; asphalt-paved visitor and employee parking area; and landscape areas. Construction of these common area facilities would require heavy to medium grading and would occur concurrently with the construction of Solar Plants 1 and 2 (Palen 2012a §2). The common facilities area would also be used for a temporary construction area, as described in "Laydown Areas" below.

The administration complex would occupy approximately 4.8 acres and would be served by power from the local 33-kV distribution system and water from water supply wells located in the common area. Similar to the power plant sites, storm water management for the administration complex would include a permanent diversion channel comprising an engineered earthen berm and adjacent swale with rock slope protection. The surface areas within the common area that are used for construction activities would be stabilized and dust suppression maximized with a layer of crushed stone in areas subject to heavy daily traffic (Palen 2012a §2).

Laydown Areas

The 203-acre temporary construction laydown area on the west side of the site would be used for equipment laydown, construction parking, construction trailers, a tire cleaning station, heliostat assembly facility, a temporary concrete batch plant, and other construction support facilities. The surface areas within the temporary construction area that are used frequently would be stabilized and dust suppression maximized with a layer of crushed stone in areas subject to heavy daily traffic. The temporary construction laydown area has been sized large enough to allow the staging of deliveries and truck and worker ingress and egress to the site to avoid stacking on the I-10/Corn Springs interchange (Palen 2012a §2.6).

Additionally, 11.2 acres of temporary construction laydown areas would be located at each solar plant site for construction parking and equipment laydown. To redirect storm water flow around these construction laydown areas, diversion berms or drainage swales would be used. Stone filters and check dams would be placed, as needed, to provide areas for sediment deposition (Palen 2013g). Areas compacted during construction activities would be restored, as appropriate, to approximate preconstruction compaction levels to minimize the opportunity for any increase in surface runoff (Palen 2013e §3.4).

Linear Facilities

Off-site

The approved project did not include a natural gas supply pipeline, but rather was approved to use liquefied petroleum gas contained within a tank for its auxiliary fuel. The modified project would use natural gas to fire its auxiliary and nighttime preservation boilers. The natural gas supply for PSEGS would be provided by Southern California Gas (SoCal Gas), which would upgrade and extend an existing distribution line from its main transmission gas pipeline located approximately 1.8 miles west and south of the site. The modified project also includes a slight re-routing of the generation tie-line and the redundant telecommunication line near the western end of the approved route, around the newly constructed Red Bluff Substation (Palen 2012a §2).

On-site

During construction, trenches would be excavated for the installation of underground systems, equipment and materials including onsite electrical transmission system conductors and onsite natural gas system. The natural gas supply lines would be extended onsite to serve both Solar Plants.

The approved project proposed overhead transmission lines to transport electricity generated at the power blocks to the onsite switchyard. The modified project proposes underground electric cables for this purpose. The cable from Solar Plant 2 would be routed to Solar Plant 1 adjacent to major access roads. Cables serving each Solar Plant would then be routed to the onsite switchyard (Palen 2013r §20).

The typical trench would be 2-3 feet wide at the base and 3-6 feet deep, but a few trenches may have widths and/or depths up to 12 feet. In addition, buried conductors would require manholes located at intervals of approximately 1,000 to 2,000 feet for cable pulling during construction. The manholes would be approximately 8-10 feet in depth. Trench sides would be sloped or shored in accordance with applicable safety requirements to prevent trench walls from collapsing (Palen 2012a §2.13).

Total Soil Disturbance

Construction of the PSEGS would affect the areas shown on **Project Description Figure 6**. Soil disturbance would occur as a result of grubbing, grading, and excavation activities. After construction, some of these areas would be covered with impervious material (i.e. concrete foundations, asphalt pavement, heliostat assemblies) and temporary construction areas would be restored to pre-project grade and stabilized to prevent erosion and promote natural re-vegetation.[5] **Soil & Water Resources Table 4** summarizes the estimated graded areas and impervious areas.

[5] As required by Condition of Certification **BIO-8**, Item 22 (see the **BIOLOGICAL RESOURCES** section of this FSA).

Soil & Water Resources Table 4
Estimated Graded Areas and Impervious Areas

Graded Areas		Percent of Total Project Area[(1)]
Dirt Roads	244 acres	9.2%
Power Blocks	102 acres	
Switch Yard	3 acres	
Total	349 acres	
Impervious Areas		21.7%
Heliostats[(2)]	799 acres	
Paved Roads	25 acres	
Power Blocks		
Common Area		
Total	824 acres	
Temporary (during construction)		1.0%
Construction Laydown Area	28 acres	
Concrete Batch Plant	4 acres	
Underground electric cables	5 acres	
Natural Gas Line (onsite)	2 acres	
Total	39 acres	
Offsite Linear Facilities	339 acres	--

(Source: Palen 2012a, Palen 2013a, Palen 2013r)
Notes 1 - Solar fields (3576 acres) + Common Area (15 acres) + Laydown Area (203 acres) = 3794 acres (Does not include offsite linear facilities.)
2 - Accounts for surface area of all mirrors in horizontal position. Assuming 170,000 heliostats total, each with a 204.7 square feet reflecting surface.

Water Use

The approved project would have used up to 1,917 acre-feet per year (afy) during construction (for a total of 5,750 acre-feet during the 39 months) from up to 10 groundwater wells. The modified project would use up to the same number of groundwater wells as the approved project. However, because less extensive grading would be required for the solar field, the modified project would only use up to 400 afy (for a total of 1,130 acre-feet) during the construction period (Palen 2012a §2.4).

The modified project would require water for various construction-related activities. These activities include:

- Dust control for areas experiencing construction work as well as mobilization and demobilization;
- dust control for roadways;
- water for grading activities associated with both cut and fill work;
- water for soil compaction in the utility and infrastructure trenches;
- water for soil compaction of the site grading activities;
- water for soil stockpile sites;
- water for the various building pads;

- water for hydrostatic testing for tanks and pipelines; and
- water for concrete pours on-site.

Wastewater Management

Wastewater generated during construction would consist of similar types and quantities as the approved project (Palen 2012a §5.2). Anticipated sources of wastewater would include sanitary wastes, wash water, concrete washout water, paint wash water, piping and vessel hydrostatic test water, and drilling slurries and drilling fluids (Palen 2013e §3.11). Sanitary waste would be contained in portable facilities and routinely disposed of at an offsite treatment/disposal facility by a sanitary service. Excess concrete and concrete washout slurries would be discharged to a temporary washout facility (Palen 2013e §4.3).

PROJECT OPERATION

PSEGS would be designed for an operating life of 25 to 30 years. It is anticipated that the facilities would normally operate at high average annual capacity factors during periods of sunlight (Palen 2012a § 3.1.4). Commercial operation for both Solar Plants 1 and 2 is estimated to begin in late 2016[6] (RCSD 2013a).

Soil Erosion

The project owner submitted a Preliminary Draft Construction Drainage, Erosion, and Sediment Control Plan/Storm Water Pollution Prevention Plan ([DESCP/SWPPP] Palen 2013e) that lists standard Best Management Practices (BMPs). Disturbed areas would be stabilized with effective soil cover (such as aggregate, paving, or vegetation) as soon as feasible, but no later than 14 days after construction or disturbance is complete in that portion of the site. To reduce erosion potential, BMPs would be implemented in accordance with the approved DESCP. Vegetation would remain, but would be cut (when necessary) to a height that would allow clearance for heliostat function while leaving the root structures intact. Occasional cutting of the vegetation would be performed as needed to permit unobstructed heliostat mirror movement.

Storm Water Control

The approved project would have constructed three large drainage control channels to bypass all offsite storm water runoff around the solar fields. The modified project would instead construct much smaller diversion channels to bypass runoff around Solar Plant 1, Solar Plant 2, and the administration complex. These channels would be maintained during the operational life of PSEGS. Periodic maintenance would be conducted as required after major storm events and when the volume of accumulated material behind the check dams exceeds 50 percent of the diversion channel's designed volume (Palen 2013e §3.4).

[6] If approved, the start of construction would likely begin in spring 2014 to allow desert tortoises to be cleared from the site. Commercial operation would likely begin in late 2016 due to the delay for tortoise clearing

Areas compacted during construction activities would be restored, as appropriate, to approximate preconstruction compaction levels to minimize the opportunity for any increase in surface runoff. A majority of solar field development would maintain unobstructed sheet flow along existing natural contours and flowpaths. Relatively small rock filters and local diversion berms through the heliostat fields may be installed as required to discourage water from concentrating. Stone filters and check dams are not intended to alter drainage patterns, but to minimize soil erosion and promote sheet flow (Palen 2013e §4).

Grading and mowing during construction, and continued vegetation control during operations, could affect a large portion of the onsite ephemeral drainages over the life of the project. Despite these ongoing activities, the natural hydrologic processes would be maintained. These existing flow patterns are intermittent with variable channels, and ephemeral flows would continue to follow the same direction toward Palen Dry Lake (Palen 2013e §4.4).

Each PSEGS Solar Plant would keep the potentially polluted contact[7] storm water from the power blocks and equipment areas, general facility drainage, process wastewater, and sanitary waste completely separated from non-contact storm water runoff, as described in the Wastewater Management discussion below.

Water Use

The approved project would have used up to 300 afy during operation from up to 10 groundwater wells. The modified project would utilize the same number of groundwater wells but would only use up to 201 afy during operation. The onsite groundwater production wells would supply both solar plants and the common area with make-up water, mirror-wash water, and domestic water. Each solar plant would include a water treatment and deionizing facility in the power block area. Water for domestic uses by project employees would be provided by onsite groundwater treated to potable water standards. The estimated annual water use for this purpose is 4 afy (Palen 2012a §2.4).

Wastewater Management

PSEGS would keep the potentially polluted waste water (contact runoff, general facility drainage, process wastewater, and sanitary waste) completely separated from non-contact storm water runoff (Palen 2012a §2.8).

General Facility Drainage

Each Solar Plant would collect contact runoff from the power block to prevent this potentially contaminated water from comingling with non-contact storm water runoff. The contact runoff would be collected along with wastewater from the plant's raw water use (such as sample drains, containment area washdown, and facility equipment wash water) through a system of floor drains, hub drains, sumps, and piping and routed to the oil/water separator. From there, the water would flow to the waste collection tank then to a thermal evaporator system with the process wastewater (Palen 2012a §2.8).

[7] Contact runoff refers to storm water in contact with exposed polluted or hazardous materials and/or surfaces that can potentially result in contaminated runoff (containing trace oil, chemicals, metals, toxic substances, or other materials).

Process Wastewater

The primary wastewater collection system would collect process wastewater from all of the solar plant equipment, including blowdown[8] from the SRSG, natural-gas-fired boiler, demineralization, auxiliary cooling system, and water treatment equipment. Additional sources of wastewater include oil/water separator effluent from power block storm water runoff and general facility drainage. To the extent practical, process wastewater would be recycled and reused. A thermal evaporator system (vapor recompression evaporation system) would treat the collected wastewater by concentrating the soluble materials through evaporation. Distillate collected from the system would be recycled and routed to the well water storage tank for reuse. Concentrated waste brine from the evaporator would be transported to the evaporation ponds by tank truck (Palen 2012a §2.8).

The evaporation ponds for the approved project were located within the solar block area, with two 4-acre ponds in the approximate center of each solar field. For the modified project, the two 2-acre ponds would be located in the common area in the southwest portion of the project site. Each 2-acre pond would be divided into two cells and would be capable of evaporating the total waste stream from the entire facility for the life of the project. Two ponds allow the use of one pond when the other requires maintenance. The evaporation ponds would be double-lined with high-density polyethylene (HDPE) liners to prevent infiltration of process water into the soil below (Palen 2012a §2.8).

Sanitary Waste

Each solar plant and the administration complex would include a septic tank and leach field system for sanitary water streams, including showers and toilet. When needed, septic tank contents would be removed from site by a sanitary service. Based on the current estimate of approximately 3,010 gallons of sanitary wastewater production per day, a total leach field area of approximately 6,000 square feet would be required, spread out among three or more locations (Palen 2012a §2.8).

Mirror Washing

Regular mirror washing is anticipated to be needed once a week, and additional mirror washing may occur on an as-needed basis as determined by a reflectivity monitoring program. Mirror washing would occur primarily at night and involves a water truck spraying treated water on the mirrors in a drive-by fashion. Wash water falls from the mirrors to the ground and, due to the small volume, soaks in with no appreciable runoff. Remaining rinse water from the mirror washing operation is expected to evaporate on the mirror surface (Palen 2012a §2.4).

---

[8] Blowdown is the portion of water drained from a process to remove mineral build-up from concentrated recirculating water. These minerals would cause scaling on equipment surfaces and can damage the system.

CONTAMINATED SOIL AND WATER

A Phase I Environmental Site Assessment (ESA) performed in May 2009 for the project area concluded that no recognized environmental conditions (REC) were associated with the project site.[9] Because the ESA is required to be updated within a year if a new project is proposed, the project owner has provided an updated records search for the Phase I ESA and indicates there are still no REC's documented at the site. (Palen 2013cc §70). Although the potential of encountering contaminated soil would be low, staff would require that an experienced and qualified Professional Engineer or Professional Geologist be available for consultation during site characterization, soil grading or soil excavation to determine appropriate actions to be taken in the event contaminated soil is encountered. (Refer to the **WASTE MANAGEMENT** section of this FSA for additional information related to contaminated soil).

SETTING AND EXISTING CONDITIONS

The project is located between the communities of Blythe, California (approximately 35 miles southeast) and Desert Center, California (approximately 10 miles west).

The project site is located in the Mojave Desert Geomorphic Province. The Mojave Desert is a broad interior region of isolated mountain ranges separated by expanses of desert plains. It has an interior enclosed drainage and many playas. There are two important fault trends that control topography—a prominent NW-SE trend and a secondary east-west trend (apparent alignment with Transverse Ranges is significant). The Mojave province is wedged in a sharp angle between the Garlock Fault (southern boundary Sierra Nevada) and the San Andreas Fault, where it bends east from its northwest trend. The northern boundary of the Mojave is separated from the prominent Basin and Range by the eastern extension of the Garlock Fault.

PHYSIOGRAPHY

Physiographically, the project site lies near the toe of alluvial fans emanating from the Chuckwalla Mountains to the south, the Coxcomb Mountains to the north, and the Palen Mountains to the northeast, and is bisected by a broad valley-axial drainage that extends southward between these mountains and drains to the Palen Lake playa located a short distance north of the site (see **Soil & Water Resources Figure 2**). The elevation of Chuckwalla Valley ranges from under 400 feet at Ford Dry Lake to approximately 1,800 feet above mean sea level (amsl) west of Desert Center and along the upper portions of the alluvial fans that ring the valley flanks. The surrounding mountains rise to approximately 3,000 and 5,000 feet amsl.

[9] AECOM, Inc. "Phase I Environmental Site Assessment of Proposed Solar Power Plant Site Located in Eastern Riverside County, California". Prepared for Solar Millennium, LLC. May 2009.

The ground surface in the region of the project site generally slopes gently downward to the southeast at a gradient of less than 1 percent. Ground surface elevations at the project site itself range from approximately 680 feet amsl in the southwest to 425 feet amsl in the northeast. Steeper grades are present at isolated sand dunes along the northern portion of the site. Toward the north and central portions of the site, the ground becomes hummocky as it transitions to the flat playa located along the northern portion of the site.

CLIMATE AND PRECIPITATION

The climate in the Chuckwalla Valley, which is classified as a “low desert,” is characterized by high aridity and low precipitation. The region experiences a wide variation in temperature, with very hot summer months with an average maximum temperature of 108 degrees Fahrenheit (ºF) in July and cold dry winters with an average minimum temperature of 66.7 ºF in December. The Blythe area receives approximately 3.5 inches of rainfall per year. The majority of the rainfall occurs during the winter months, but rainfall during the late summer is not uncommon. The summer rainfall events tend to be a result of tropical storms that have a short duration and a higher intensity than the winter rains. Annual precipitation ranges from 0.02 to 0.47 inches per month for a total annual precipitation of just under four inches per year. **Soil & Water Resources Table 5** and **Soil & Water Resources Table 6** display the average monthly and annual minimum and maximum temperatures and precipitation (rainfall) from 1913 to 2008 collected from the Blythe Airport, located approximately 35 miles southeast of the project site. **Soil & Water Resources Table 7** presents average monthly evapotranspiration rates for various stations located in the region.

Average annual precipitation in the project area, based on the gauging station at Blythe Airport, is 3.59 inches, with August recording the highest monthly average of 0.64 inches and June recording the lowest monthly average of 0.02 inches. Per the National Oceanic and Atmospheric Administration (NOAA) Atlas 14 for the Southern California area, 3.51 inches of rain fall in the 100-year, 24-hour storm event.

SOILS

Soil characteristics of the project area were identified using the State Soil Geographic (STATSGO) database developed by the U.S. Department of Agriculture, Natural Resources Conservation Service (NRCS) for use in regional, multi-state, river basin, state, and multicounty resource planning. STATSGO spatial data were compiled by combining geologically and topographically related soil series found in county soil surveys into larger map units known as soil associations. These associations provide sufficient detail to establish the physical type and characteristics of soils in the project area. Soil associations of the project site are shown on **Soil & Water Resources Figure 3**, and the soil types are described in **Soil & Water Resources Table 8**. The eastern portion of the Project area is comprised of Hyder-Cipriano-Cherioni Association soil (map ID s1141) and the western portion is Rosita-Dune Land-Carista Association soil (map ID s1136).

Soil & Water Resources Table 8
Soil Mapping Units and Descriptions

Soil Series	Slope (% grade)	Characteristics
s1136 Rositas-Dune land-Carsitas		
Rositas	0 to 30	The Rositas series consists of very deep, somewhat excessively drained soils formed in sandy eolian material blown from recent alluvium. Rositas soils are on dunes and sand sheets. Somewhat excessively drained; negligible to medium runoff; rapid permeability. Rositas soils are used for growing citrus fruits, grapes, alfalfa, and truck crops. Native vegetation creosote bush, white bursage, desert buckwheat and mesquite.
Dune land		Dune land is not a soil series name but a landform (geomorphic term) indicating an aeolian collection of primarily sand-sized sediment. Due to the nature of this landform, soil formation does not commonly occur where an active dune exists.
Carsitas		Carsitas soils are nearly level to strongly sloping and are on alluvial fans, moderately steep valley fills and dissected remnants of alluvial fans, at elevations of about 220 feet below sea level to 800 feet above sea level. The climate is one of long, hot dry summers and short mild dry winters with an average annual precipitation of less than 5 inches. Torrential summer thundershowers occasionally produce enough runoff to flood the soil for brief periods. Vegetation is a sparse growth of creosote bush, white bursage, barrel cactus, mesquite, and palo verde. Where irrigation water is available, the soils are used for growing citrus fruits and grapes.
Soil Series	**Slope (% grade)**	**Characteristics**
s1141 Vaiva-Quilotosa-Hyder-Cipriano-Cherioni		
Vaiva	1 to 65	The Vaiva series consists of very shallow and shallow, well drained soils formed in slope alluvium from granite and gneiss. Vaiva soils are on hills and mountains with slopes of 1 to 65 percent. The mean annual precipitation is about 7 inches and the mean annual air temperature is about 71 degrees F. Vegetation is saguaro, littleleaf palo verde, creosote bush, ocotillo, ironwood, triangle bursage, staghorn cholla, spicebush, false mesquite, wolfberry, bush muhly, brittlebush and ratany.
Quilotosa	3 to 65	The Quilotosa series consists of very shallow and shallow, somewhat excessively drained soils that formed from granitic and metamorphic rocks. Quilotosa soils are on hills and mountains and have slopes of 3 to 65 percent. The mean annual precipitation is about 7 inches and the mean annual air temperature is about 70 degrees F. Vegetation is saguaro, littleleaf palo verde, brittlebush, creosote bush, ocotillo, ironwood, triangle bursage, white bursage, cholla, forbs and grasses.
Hyder	1 to 65	The Hyder series consists of very shallow to shallow, somewhat excessively drained soils that formed in alluvium from rhyolite and related volcanic rocks. Hyder soils are on mountains and hills. Somewhat excessively drained; medium to rapid runoff; moderate or moderately rapid permeability. The native vegetation is creosote bush, white bursage, brittlebush, buckhorn cholla, and littleleaf palo verde.

Soil Series	Slope (% grade)	Characteristics
Cipriano	0 to 55	The Cipriano series consists of shallow and very shallow to hardpan, somewhat excessively drained soils that formed in fan alluvium from volcanic rock. Cipriano soils are on fan terraces. Somewhat excessively drained: slow to medium runoff; moderate permeability. Present vegetation is creosote bush, palo verde, stagholll and chainfi'uit eholla, saguaro, ocotillo, and triangle bursage with some fluffgrass and six weeks grama.
Cherioni	0 to 70	The Cherioni series consists of very shallow and shallow, somewhat excessively drained soils that formed in slope alluvium on volcanic bedrock. Cherioni soils are on fan terraces or hills. Somewhat excessively drained; medium to rapid runoff; moderate permeability. Present vegetation is creosote bush, palo verde, saguaro, cholla, ocotillo, triangleleaf bursage and ratany.

A preliminary site reconnaissance was conducted at the project site by CH2MHill in 2008, during which two soil samples were collected. Based on the reconnaissance and the two samples, soils on-site were described as consisting of sandy material and classified as poorly graded sand with silt. Across most of the subject property, the soils would be expected to range from silty sand to poorly graded sand with silt.

Typical fines content in these soils would be expected to be in the range of 5 to 35 percent. Characterization of soils was made through field observations and laboratory testing by AECOM (Solar Millennium 2010a). Laboratory textural analysis and field observations characterized the on-site soils as being predominantly sands. Soil profiles observed in the test pits were typically sands and laboratory analysis measured sand content from 83 to 94 percent. Silt content measured in the soils ranged from 2 to 8 percent, and clay content from 2 to 11 percent. Observed profiles exhibited a range of effervescence from no effervescence to slight in the top layers to increasing effervescence with increasing depth indicating the presences of carbonates.

GEOLOGY

The project site is situated within the central portion of Chuckwalla Valley, an east-southeast trending valley in California’s Mojave Desert Geomorphic Province. The Mojave Desert Geomorphic Province is a wedge-shaped interior region separated from the Sierra Nevada and Basin and Range Provinces to the northwest by the Garlock Fault and its eastward extensions, and is bounded to the southwest by the Transverse Range and Colorado Desert Provinces, the San Andreas Fault, and its southern extensions. The Mojave Desert Geomorphic Province is characterized by northwest-southeast as well as east-west trending structures and mountain ranges, separated by desert valleys and plains with many enclosed drainages and playas.

Regional & Local Geology

The region has undergone a complex geologic history that includes sedimentation, volcanic activity, folding, faulting, uplift, and erosion. The project area is underlain by Holocene to Miocene basin fill deposits (Stone 2006). These deposits include younger alluvium, older (Pleistocene) alluvium, the Pliocene Bouse Formation, and the Miocene fanglomerate. The uppermost alluvium in the basin consists of Holocene to Pleistocene alluvial fan, valley axial (fluvial), playa (dry lake), and Aeolian (wind blown) deposits.

Quaternary Alluvium

Quaternary alluvial fill in the basin consists of Holocene to Pleistocene alluvial fan and valley axial (fluvial or stream) deposits, as well as lacustrine (lake) and playa (ephemeral lake) deposits (CDWR 2004). These deposits consist of gravel, sand, silt, and clay (CDWR 1963). In general, coarser alluvial fan deposits are expected near the valley edges and grade into finer distal fan deposits that interfinger with fine-grained lacustrine and playa deposits near the center of the basin. These deposits are typically heterogeneous. Valley axial drainages tend to be more uniform and continuous, and contain a greater proportion of sand and fine gravel. Portions of the basin are also occupied by aeolian (wind blown) sand deposits, but the identified aeolian deposits occur at the ground surface and are of limited thickness. The Quaternary sediments include the Pleistocene-age Pinto Formation, which consists of coarse fanglomerate (cemented, consolidated, or semiconsolidated alluvial fan gravels) containing boulders and lacustrine clay with some interbedded basalt (CDWR 2004).

Pliocene Bouse Formation

The Pliocene Bouse Formation underlies the Quaternary sediments. The Bouse Formation includes a marine to brackish-water estuarine sequence deposited in an arm of the proto-Gulf of California (Stone 2006; Wilson and Owen-Joyce 1994). This formation has alternatively been interpreted as, or may include, lacustrine sediments deposited in a closed, brackish basin (Stone 2006). The Bouse Formation is widely reported in the Colorado Valley and tributary basins in southeastern California and descriptions of this formation come from occurrences outside of Chuckwalla Valley. It is reported to be composed of a basal limestone (marl) overlain by interbedded clay, silt, sand, and tufa. The top of the Bouse Formation is relatively flat-lying with a reported dip of approximately 2 degrees south of Cibola (Metzger et al. 1973).

Miocene Fanglomerate

The Bouse Formation is unconformably underlain by a fanglomerate composed chiefly of angular to subrounded and poorly sorted partially to fully-cemented pebbles with a sandy matrix (Metzger et al. 1973). The fanglomerate is likely Miocene-age; however, it may in part be Pliocene-age (Metzger et al. 1973). The Fanglomerate represents composite alluvial fans built from the mountains towards the valley and the debris of the fanglomerate likely represents a stage in the wearing-down of the mountains following the pronounced structural activity that produced the basin and range topography in the area (Metzger et al. 1973). Bedding surfaces generally dip from the mountains towards the basin. The fanglomerate reportedly dips between 2 and 17 degrees near the mountains due to structural warping (Metzger et al. 1973). The amount of tilting indicates a general decrease in structural movements since its deposition (Metzger et al. 1973).

Bedrock

Bedrock beneath the project site consists of metamorphic and igneous intrusive rocks of pre-Tertiary age that form the basement complex (CDWR 1963), including Proterozoic schist and gneiss, Paleozoic sedimentary rocks, and Mesozoic sedimentary and metavolcanic rock sequences (Stone 2006). In some areas of the Chuckwalla Valley, volcanic rocks of Tertiary age overlie the basement complex (CDWR 1963). The bedrock topography in the study area, as interpreted by modeling of Bouger gravity data obtained from the United States Geological Survey (USGS) and interpreted by Worley-Parsons (2009), is illustrated in **Soil & Water Resources Figure 4**.

Mapped Geologic Units at the Project Site

Solar Millennium, the project owner of PSPP, reported that there are three mapped geologic units within the project limits (Solar Millennium 2010a). These units are listed and described below:

- Dune Sand (Qs), fine grained sand and silt deposited by wind. These deposits occur on the surface primarily in the northern portion of the site, but buried dune deposits were observed in test pits in the southern part of the site. However, for the purpose of this investigation, no distinction between alluvium and dune sands was made on the boring and test pit logs.
- Alluvium (Qal), fine to medium sand with silt and gravel. In general the alluvium will be coarser grained towards the south and fine towards the lake bed, but interfingering of alluvial layers and fine grained lake deposits should be anticipated at depth.
- Lake deposits (Ql), alternating layers of fine grained clay, silt, and sand deposits with varying mixtures of fine gravel.

Soil & Water Resources Figures 5A and 5B present a generalized geologic map of the project site.

Regional Tectonic Setting

The Mojave Desert comprises an area bounded by the seismically active Salton Trough to the west and southwest, and the Garlock Fault to the north. To the east and southeast it is bounded by the Sonoran Desert subprovince, a relatively stable tectonic region located in southeastern California, southwestern Arizona, southern Nevada, and northern Mexico (Balderman et al. 1978). Chuckwalla Valley is located in the eastern Mojave Desert province in an area that is relatively stable tectonically. Faults in the area occur primarily in Tertiary and pre-Tertiary strata and are related to compressional tectonism along a convergent Andean and island arc margin in the Mesozoic, and extensional detachment and block faulting during Tertiary time. No faults of Quaternary age are known to exist near the project site.

Local Faulting

The project site lies within the eastern part of Riverside County in a part of California considered to be very seismically quiescent. Although there are several bedrock faults off-site in the mountains surrounding Chuckwalla Valley, these do not exhibit recent activity and are presumed to be Tertiary or pre-Tertiary in age (Stone 2006). In addition, gravity anomalies suggest the presence of several subsurface faults beneath Chuckwalla Valley in the vicinity of the project area (Stone 2006; Rotstein et al. 1976). The gravity anomalies reflect abrupt changes in basement elevation strongly suggestive of dip-slip movements. In addition, some of these faults may have undergone right-lateral strike slip movements. These faults are presumed Tertiary and likely inactive with very low chance of earthquakes.

GEOMORPHOLOGY

This section describes the nature of, origin, processes, and development of dunes that are a critical habitat to the Mojave fringe-toed lizard (MFTL) that occupies areas on and adjacent to the right of way (ROW) for the project.

The proposed modified project footprint covers several different land units including (from southwest to northeast) a stable coarse gravel alluvial fan surface, a more active wind-blown sand area with relatively shallow sand deposits, and an area of deeper and more active vegetated sand dunes (see **Biological Resources Figure 5**) that appears to be MFTL habitat (for a discussion on the MFTL habitat, please see **BIOLOGICAL RESOURCES** of this FSA). The site is crossed by a series of small distributary alluvial fan channels, and two large wash complexes formed by concentrated drainage under the Interstate-10 freeway (I-10).

Most of the proposed western solar array lies in a relatively stable area of alluvial fan, where the offsite geomorphic impacts would be relatively minor except for impacts to the large wash complex that crosses the south east corner of the western array. This wash supports a corridor of sand dunes and associated MFTL habitat around it, and it would be necessary to either avoid or mitigate for impacts to this area. The proposed eastern solar array is located in a much more geomorphically active area, and cuts into the combined PDL-Chuckwalla and Palen wind-borne sand transport corridor (see **BIOLOGICAL RESOURCES**, Appendix A of this FSA).

HYDROGEOLOGY

Groundwater Basins

The site is located within the Chuckwalla Valley Groundwater Basin (CVGB) (CDWR Basin No. 7-5), which has a surface area of 940 square miles underlying Chuckwalla Valley (CDWR 2004). The CVGB is an unadjudicated groundwater basin and owners of property overlying the basin have the right to pump groundwater from the basin for reasonable and beneficial use, provided that the water rights were never severed or reserved. In addition, groundwater production in the basin is not managed by an entity and no groundwater management plan has been submitted to the California Department of Water Resources.

The site location in the basin is shown on **Soil & Water Resources Figure 2**. The CVGB is bounded by the consolidated rocks of the surrounding mountains. Three water-bearing Quaternary- and Tertiary-age sedimentary units overlie non-water bearing bedrock in the CVGB (CDWR 2004; CDWR 1963). Department of Water Resources (DWR) reports the maximum thickness of these deposits as about 1,200 feet in the CVGB (CDWR 1979); however, modeling of Bouger gravity data obtained from USGS suggest greater depths to bedrock exist in some parts of the basin (See **Soil & Water Resources Figure 4**).

The basin is bounded upgradient by two other groundwater basins that include the eastern part of the Orocopia Valley (CDWR Basin No. 7-31) and Pinto Valley (CDWR Basin No. 7-6) groundwater basins and down gradient by the Palo Verde Mesa (CDWR Basin No. 7-5) Groundwater basin. A brief overview of the adjoining basins follows:

Eastern Orocopia Valley (7-31)

This basin underlies Orocopia Valley, northeast of the Salton Sea, in central Riverside County. It is bounded by impermeable rocks of the Cottonwood and Eagle Mountains on the north and of the Orocopia and Chocolate Mountains on the south (see **Soil & Water Resources Figure 2)**. The basin is bounded by a section of the San Andreas Fault zone and semi-permeable rocks of the Mecca Hills on the west and by a bedrock constriction on the east. The western portion of the valley drains westward toward the Salton Sea, but the eastern part drains eastward into Hayfield (dry) Lake and Chuckwalla Valley. Average annual precipitation ranges to 4 inches (CDWR 2003).

Pinto Valley (7-6)

This groundwater basin underlies Pinto Valley in northern Riverside County (see **Soil & Water Resources Figure 2)**. It is bounded by nonwater-bearing rocks of the Coxcomb Mountains on the east and northwest, the Pinto Mountains on the north, of the Eagle Mountains on the south, and the Hexie Mountains on the west (Bishop 1963; Jennings 1967). The valley is drained eastward by the Fried Liver, Smoketree, and Porcupine Washes (Jennings 1967). Average annual precipitation ranges to 6 inches (CDWR 2003).

Palo Verde Mesa (7-39)

This basin underlies Parker Valley in eastern Riverside County (see **Soil & Water Resources Figure 2)**. The basin is bounded by nonwater-bearing rocks of the Big Maria and Little Maria Mountains on the north, the McCoy and Mule Mountains on the west, the Palo Verde Valley on the east, and of the Palo Verde Mountains on the south (CDWR 1979; Jennings 1967). The northwest boundary and parts of the western boundary are drainage divides (Metzger 1973; Jennings 1967). The valley is drained by the McCoy Wash to the Colorado River. Average annual precipitation ranges to 6 inches (CDWR 2003).

Groundwater Inflow/Outflow

Natural groundwater recharge to the CVGB includes recharge from precipitation and subsurface inflow from the Pinto Valley Groundwater Basin to the northwest and the Orocopia Valley Groundwater Basin to the Southwest (CDWR 2004; Eagle Crest 2009). Underflow from the Cadiz Valley Groundwater Basin has also been hypothesized by DWR (2004); however, recent work has reportedly confirmed that the Cadiz Valley Groundwater Basin does not contribute inflow to the CVGB (BV and WCC 1998). CVGB also shares a boundary with the Ward Valley Groundwater Basin, but groundwater is not reported to flow across this boundary (Bedinger et al. 1989). Other sources of recharge to the basin include agricultural return flow and return flow from treated wastewater disposal.

Groundwater Inflow

Recharge from Precipitation

In this part of California, almost all moisture from rain is lost through evaporation or evapotranspiration and runoff occurs principally during intense thunderstorms (CRBRWQCB 2006). Most recharge from precipitation occurs when runoff from the surrounding mountains exits bedrock canyons and flows across the coarse sediments deposited in the proximal portions of the alluvial fans that ring Chuckwalla Valley. To a lesser extent, recharge occurs from infrequent precipitation or runoff on the valley floor (CDWR 2004). The area of the Chuckwalla Valley watershed encompasses Chuckwalla Valley (601,543 acres) and the surrounding bedrock mountains (258,825 acres), for a total area of approximately 860,368 acres. Available estimates of recharge in CVGB are variable and in some cases based on incomplete or incorrect data. DWR has not published an estimated recharge rate for the basin (CDWR 2004). In 1986, Woodward Clyde calculated recharge from precipitation for the Chuckwalla Valley watershed to be 29,530 afy (Woodward Clyde 1986). This equates to an average recharge rate of approximately 0.036 feet per year (0.4 inches). Woodward Clyde reported this number as approximately 12.8 percent of an average annual precipitation of 3.39 inches per year across the watershed; however, this was the average annual precipitation in Blythe at the time, and does not consider that the orographic effect of the surrounding mountains which results in precipitation rates of over 6 inches per year in the higher elevation portions of the watershed (Hely and Peck 1964). In 1992, the average recharge to CVGB was reportedly estimated by the United States Bureau of Land Management (BLM) and the County of Riverside to be 5,540 to 5,600 afy based upon an assumed 10 percent infiltration of precipitation (Eagle Crest 2009); however, this number evidently considered only a portion of the watershed as it would equate to an average annual precipitation depth of only about 1 inch per year across the watershed. Recent studies have demonstrated recharge rates for nearby desert basins ranging from approximately 3 to 5 percent of the total incident precipitation on the basin catchment area (Whitt and Jonker 1998). A review of recharge studies in the arid southwest performed by USGS (2007b) cited a wide range of recharge rates, but rates in similar basins ranged from about 3 to 7 percent.

For this study, recharge from precipitation was estimated by overlaying isohyetal maps prepared by Hely and Peck on the Chuckwalla watershed boundaries and calculating the volume of average annual precipitation for each of four precipitation zones for the valley and bedrock portions of the watershed. The calculated average annual precipitation volume for the watershed is 258,000 acre-feet (af). Recharge for the CVGB estimated as a fraction of 3, 5 and 7 percent of total incident precipitation is therefore calculated to be 8,588, 14,313, and 20,038 afy, respectively.

An analysis of infiltration and runoff rates for the CVGB is provided in **Soil & Water Resources Table 9.**

Soil & Water Resources Table 9
Estimates of Runoff and Infiltration in Chuckwalla Valley Groundwater Basin

Layer (a)	Area (acres)	Mean Annual Precipitation (inches) (b)	Total Volume of Rainwater from Mean Annual Precipitation (af)	Runoff Curve Classification	Runoff Curve Number (b)	Runoff (percent of Precipitation)	Total Annual Volume of Infiltration – Hely & Peck (af)	Total Annual Volume of Infiltration (af) based on 3 % (c)	Total Annual Volume of Infiltration (af) based on 5%(c)	Total Annual Volume of Infiltration (af) based on 7%c)

Based on the above analysis, approximately 36 percent of precipitation in the watershed falls on the bedrock areas that ring the watershed. This is significant because precipitation that falls on the valley floor is not expected to contribute consistently to recharge. Studies published by USGS report approximately 7 to 8 percent of precipitation falling on bedrock mountains in other arid basins goes to mountain front recharge (USGS 2007a). Accordingly, the 36 percent of the precipitation that falls on the bedrock areas would be equivalent to approximately 3 percent of the total precipitation that falls on the Chuckwalla Valley watershed. In the absence of more detailed study, 3 percent of total precipitation falling on the Chuckwalla Valley watershed (8,588 afy) is used as a reasonable lower bound estimate of recharge to the CVGB.

Subsurface Inflow

Under natural conditions, subsurface flow occurs from only two sources, subsurface underflow from the Pinto Valley Groundwater Basin and the Orocopia Valley Groundwater Basin. Underflow from the Colorado River is not expected to occur under natural conditions. Underflow from the Pinto Valley Groundwater Basin has been calculated to be 3,173 afy (GeoPentech 2003, Eagle Crest Energy Company 2009). Inflow from the Orocopia Valley Groundwater Basin has been estimated to be 1,700 afy (LCA 1981). CH2M Hill (1996) estimated the combined subsurface inflow from both basins to be 6,700 afy. However, recent studies by GeoPentech reportedly indicate that subsurface inflow from Orocopia Valley Groundwater Basin may be as low as several hundred afy. Therefore a combined subsurface inflow rate of 3,500 afy was assumed for both basins for water budget purposes.

Wastewater Return Flow

Chuckwalla State Prison was constructed approximately 22 miles southeast of the project site in 1988, and the adjacent Ironwood State Prison became operational in 1994. The prisons use an unlined pond to dispose of treated wastewater, and a large percentage of this discharge is reported to infiltrate into the subsurface and recharge the CVGB. For the years 1998 through 2001, the California Department of Water Resources – Department of Planning and Local Assistance (CDWR-DPLA) reported that deep percolation of applied urban water in the Chuckwalla Planning Area (assumed to be wastewater return flow) was 500 to 800 afy (CDWR-DPLA 2007). According to authorities at the State prison complex (Lanahan 2009), they indicated that approximately 600 afy of treated effluent recharges the basin. Recently published water budget information for the Eagle Crest Pumped Storage Project (Eagle Crest 2009), indicates 795 afy of treated effluent are recharged by the prisons. An additional source of wastewater return flow in the basin is approximately 36 afy from the Lake Tamarisk development near Desert Center (Eagle Crest 2009). Combining these two flows, staff estimates wastewater return of 831 afy which is included in **Soil & Water Resources Table 10**.

Irrigation Return Flow

The amount of applied irrigation water that returns to recharge a groundwater basin depends on the soil, crop type, amount and method of irrigation, and climatic factors. Woodward Clyde (1986) reported an irrigation efficiency of 60 percent (return flow of 40 percent) for jojoba crops in Chuckwalla Valley. DWR-DPLA reported an irrigation efficiency of 72 percent (return flow of 28 percent) for subtropical crops in the Palen

Detailed Analysis Unit (DAU) of the Chuckwalla Planning Area (CDWR-DPLA 2007). In its water budget calculations for the Chuckwalla Planning Area in support of California Water Plan updates, DWR-DPLA calculated an irrigation return flow of approximately 9 to 11 percent for 1998, 2000 and 2001, respectively. A 10 percent return flow is a reasonable factor for deep percolation from irrigation in the basin, and was applied to the assumed agricultural and landscape water demand in the basin for the purposes of a water budget. Current pumpage associated with activities associated with irrigation return flow is estimated to be approximately 7,700 afy in the CVGB that includes 6,400 afy for agriculture, 215 afy for aquaculture pumping, and 1,090 afy for Tamarisk Lake (Worley-Parsons 2009). Return flows are calculated using the 10 percent or approximately 800 afy and are included in **Soil & Water Resources Table 10**.

Groundwater Demand/Outflow

Groundwater provides the only readily available natural water resource in Chuckwalla Valley. While the Colorado River Aqueduct traverses the northern portion of the basin, it does not contribute significant water to the basin (other than leaks and maintenance activities). In addition, any water diverted from the aqueduct would require entitlement. Designated and potential beneficial uses of groundwater in the basin include domestic, municipal, agricultural and industrial use (CRBRWQCB 2006). As such, groundwater demand is a significant contributor to basin outflow. Other sources of basin outflow include subsurface discharge to the Palo Verde Mesa Groundwater Basin, and evapotranspiration at Palen Lake.

Groundwater Extraction

Current and historical groundwater pumpage in CVGB includes agricultural water demand, pumping for Chuckwalla and Ironwood State Prisons, pumping for the Tamarisk Lake development and golf course, domestic pumping, and a minor amount of pumping by Southern California Gas Company. In addition, historical pumpage included water supply for the Kaiser Corporation Eagle Mountain Mine. With the exception of pumping for Chuckwalla Valley and Ironwood State Prisons, most of the current groundwater pumping in the basin occurs in the western portion of the basin, near the town of Desert Center. Current pumpage is estimated to be approximately 7,900 afy in the western CVGB and 2,605 afy in the eastern basin. Agricultural production is limited to the western portion of the basin (Eagle Crest 2009; CDWR-DPLA 2007 and 2009), with the exception of a relatively limited amount of acreage that is associated with the state prisons.

Subsurface Outflow

Subsurface outflow to Palo Verde Mesa Groundwater Basin was estimated by Metzger (1973) to be 400 afy. This calculation was based on a cross sectional profile of the boundary between the two basins derived using geophysical methods and regional data regarding groundwater gradients and hydraulic conductivity. Woodward Clyde (1986) revised this estimate based on the results of pump testing at Chuckwalla State Prison and calculated the basin outflow to be 870 afy. Engineering Science (1990) updated this estimate to 1,162 afy, presumably as a result of return flow from prison wastewater disposal; however, the rationale for this adjustment was not provided. Using more recent gravity data, Wilson and Owens-Joyce (1994) found that the area through which discharge occurs is significantly more limited than previously thought due to the presence of a buried bedrock ridge. As a result, the most recent available water budget for the basin has adopted an outflow rate of 400 afy (Eagle Crest 2009).

Palen Lake Evapotranspiration

Regional groundwater flow and discharge mapping performed by USGS (Bedinger et al. 1989) did not identify Palen Lake as an area where groundwater discharges at the ground surface. Nevertheless, groundwater elevation contour mapping suggests that groundwater may occur near the ground surface beneath approximately the northwestern 25 percent of Palen Lake. It is therefore possible that a portion of Palen Lake is operating as a wet playa. Groundwater levels beneath the southeastern portions of Palen Lake, and a small ancillary playa located approximately one mile southeast of Palen Lake, were reported by Steinemann (1989) as being 20 to 30 feet below ground level, suggesting that Palen Lake would be a dry playa at various times.

Review of aerial photography indicates what appears to be a relatively small area of dissected salt pan near the northern and western sides of the playa. Because the salt pan is dissected, it is not clear whether salt deposition is actively occurring or whether this material is residual deposition from surface water evaporation. Immediately northwest of Palen Lake, between Palen Lake and Desert Center-Rice Road, Pleistocene lake bed deposits crop out at the ground surface in the form of dissected, mesa-like prominences that are 5 to 10 feet high (CDWR 1963). These deposits are capped with a layer of caliche and locally support scattered mesquite trees. There does not appear to be any other evidence of shallow groundwater or evapotranspiration visible in aerial photography.

Groundwater elevation contour mapping (Steinemann 1989) suggests that groundwater may occur near the ground surface beneath approximately the northwestern 25 percent of Palen Lake. A well located approximately two miles north of Palen Lake, is reported to be completed to a depth of 501 feet below ground surface and has a ground surface elevation of 500 feet amsl (WorleyParsons 2009). A screened interval for the well is not reported. Groundwater levels in this well were reported to be approximately 20 to 25 feet below the ground surface (bgs) between 1932 and 1984. Given that the surface elevation at Palen Lake two miles to the south is approximately 460 feet amsl, or 40 feet lower, it appears possible that groundwater levels are very close to the ground surface beneath the northern portion of the playa. In addition, DWR (1963) identified the presence of mesquite trees on low mesa-like promontories of Pleistocene lacustrine sediments at the northwest margin of Palen Lake playa, also suggesting the possible presence of relatively shallow groundwater. These data suggest it is possible that an area in the northern portion of Palen Lake is discharging groundwater by evaporation as a wet playa. Groundwater levels beneath the southeastern portions of Palen Lake, and a small ancillary playa located approximately one mile southeast of Palen Lake, are 20 to 30 feet bgs (Steinemann 1989), indicating these are dry playa areas.

Review of aerial photography indicates an approximately 700-acre area of dissected salt pan in the northwest portion of the playa (Worley-Parsons 2009). This feature is surrounded by an additional approximately 1,300 acres that show evidence of more limited surface salt accumulation. The extent of this area is visible in aerial imagery from November 2005, and was generally confirmed by a reconnaissance performed on December 10 and 30, 2009. Review of the historical progression aerial imagery (Worley-

Parsons 2009) indicates no or limited salt accumulation in this area from 1996 through 2002, light salt accumulation in March of 2005, and the currently observed salt pan area in November 2005. This suggests that salt pan accumulation in the playa is episodic; however, seasonal, intermittent accumulation cannot be ruled out. Historical precipitation records indicate that 2005 rainfall in Blythe was approximately twice the long term annual average, with 5.10 inches occurring in January and February 2005 (WRCC 2009), just before the March 2005 aerial photograph was taken. These storm events would be expected to have resulted in the accumulation of runoff in Palen Lake, and consequently in dissolution and re-crystallization of salt deposits during evaporation of surface water, and by wetting and subsequent drying of salt containing playa sediments. As such, these rainfall events are likely responsible for at least a portion of the observed salt accumulation; however, groundwater discharge by evaporation at the ground surface could also be responsible.

During a December 10, 2009 site visit by Worley-Parsons (2009), conditions at the northwestern edge of the playa were investigated. Intermittent salt deposits were observed to be located both in low lying areas and on the tops of low, dissected, mesa-like promontories of Pleistocene lacustrine sediments approximately three feet high that extend into the playa. Deposition of salt by groundwater evaporation at the surface would be expected to occur on the sides as well as the top of these promontories. The occurrence of salt deposits on the top, but not on the sides, suggests that these deposits are the result of salt dissolution from layers with elevated salt content and redeposition as soil moisture evaporates at the ground surface. The shallow soil beneath the salt deposits was observed to be wetted to a depth of approximately three inches from a recent rain event, but underlying soil to depths of approximately one foot were observed to be generally dry. As such, evidence of salt deposition by evapotranspiration at the playa surface was not observed in this area during Worley-Parsons' reconnaissance (Worley-Parsons 2009).

Mesquite trees were observed in the area north of the playa, but wetland species or other species indicative of or dependant on shallow groundwater were not observed. Mesquite trees are typically thought to be associated with "shallow" groundwater; however, the term shallow should be understood in a relative sense—the depth to groundwater utilized by mesquite trees may be several tens of feet below the ground surface. This would be too deep to support groundwater discharge at the ground surface. Thus, the presence of mesquite is not necessarily indicative of discharging playas.

In December 2009, Worley-Parsons advanced two hand auger borings to approximately 10 feet bgs beneath the salt pan area in the northwest portion of the playa. The moisture content of the soil was observed to increase with depth in both borings, and free groundwater was encountered at a depth of approximately 8 feet below the playa salt pan surface in one of the borings. Subsurface soil encountered consisted of alternating layers of clay/silt mixtures and sandy sediments. A depth of 6 to 10 feet is generally the maximum depth of free water documented beneath discharging playas. This suggests that groundwater could be shallow enough to discharge at the surface by capillary rise and evaporation to occur at least some of the time (Worley-Parsons 2009).

Based on the above data, salt accumulation at Palen Lake is likely the result of dissolution and recrystallization of existing salt deposits during times of surface water inflow, as well as limited episodic and possibly seasonal or intermittent groundwater discharge. The rate of groundwater discharge in a wet playa is dependent on the depth to groundwater and magnitude of upward vertical gradients, the ability of subsurface materials to facilitate capillary rise, climatic conditions, and the presence and extent of free water, wetlands and salt pans on the playa surface (Tyler 2005; Allen and Sharike 2003). In general, groundwater discharge rates are highest when groundwater is shallow, temperatures are high, and when open water or wetlands are exposed at the playa surface.

Increased depth to groundwater, lower temperatures, the presence of coarse grained material that inhibits capillary rise, and the presence of salt pan (which increases albedo) tends to decrease groundwater discharge rates. Based on these factors, discharge of groundwater at Palen Lake appears to be limited based on the depth to groundwater (including absence of vegetation that indicates consistent shallow groundwater), the presence of coarse grained layers that limit capillary rise and the apparent intermittent or episodic nature of discharge.

Groundwater discharge rates were estimated based on reported groundwater discharge rates at other playas, the area of identified salt accumulation, and the evident episodic or intermittent nature of salt accumulation. Measured evapotranspiration rates at Franklin Lake Playa were used to form a basis for this estimate (Czarnecki 1997). Franklin Lake Playa is a well developed and extensively characterized wet playa in the Death Valley area (USGS 2007b). Evapotranspiration rates at Franklin Lake Playa are calculated to be 38 to 41 cm/year (0.108 to 0.116 feet/acre/month) based on the Energy-Balance Eddy-Correlation method, which is reported to be the most reliable method by the USGS. These rates would be a conservative measure of evapotranspiration for active wet playa areas at Palen Lake for the following reasons:

- Franklin Lake Playa is a terminal playa, which is the terminal discharge point of the local groundwater flow system; whereas, Palen Lake is a bypass playa, with most groundwater flowing laterally past the playa.
- Franklin Lake Playa includes extensive groundwater discharge features (e.g., saltpan, puffy ground and halophyte wetlands) that are generally less developed or lacking at Palen Lake, indicating less groundwater discharge would be expected at Palen Lake.
- Evapotranspiration rates at wet playas are temperature dependant, with maximum rates occurring during the summer months. Franklin Lake Playa occurs in Death Valley, where mean annual and summer high temperatures typically exceed those at Palen Lake.
- The available data suggest that groundwater discharge, if it is occurring at Palen Lake, is episodic or intermittent; whereas groundwater discharge at Franklin Lake Playa occurs throughout the year.

The total area of potential groundwater discharge at Palen Lake is estimated to be approximately 2,000 acres, with salt pan occupying approximately 700 acres of this total. Given the differences between Palen Lake and Franklin Lake Playa previously discussed, a groundwater discharge rate that is approximately half that at Franklin Lake Playa was adopted (approximately 0.0583 feet/acre/month of water) and was believed to occur. Over an area of 2,000 acres for three months of the year, this equates to approximately 350 afy.

Groundwater Budget

The perennial yield[10] of CVGB was estimated to be between 10,000 and 20,000 afy (Hanson 1992). A perennial yield of 12,200 afy was adopted in the Environmental Impact Statement for the Eagle Crest Landfill project in 1992 (BLM and County of Riverside 1992); however, the amount of recharge from precipitation used to derive this number appears to be based on recharge to only a portion of the basin, so the perennial yield may be underestimated.

Staff compiled a comprehensive water budget based on published literature, water budget information collected by the DWR for updates to the California Water Plan, information obtained from the California State Prison Authority, and the analysis of basin inflow and outflow discussed in the previous two sections. This information is summarized in **Soil & Water Resources Table 10**, below.

Soil & Water Resources Table 10
Groundwater Budget (afy)

Budget Components	**Totals**
Inflow	
Recharge from precipitation	8,588
Underflow from Pinto Valley and Orocopia Valley Groundwater Basins	3,500
Irrigation return flow	800
Wastewater return flow	831
Total inflow	13,719
Outflow	
Groundwater extraction	–10,361
Underflow to Palo Verde Mesa Groundwater Basin	–400
Evapotranspiration at Palen dry lake	–350
Total outflow	–11,111
Budget balance (net Inflow)	2,608

The analysis suggests that the CVGB is in positive balance (inflow exceeds outflow) by approximately 2,600 afy under average conditions.

[10] Perennial yield is the maximum quantity of water that can be annually withdrawn from a groundwater basin over a long period of time (during which water supply conditions approximate average conditions) without developing an overdraft condition (CDWR 1998).

Water Bearing Units

The following water-bearing formations have been identified in the CVGB. The extent and relationship of these formations is presented in hydrostratigraphic cross sections A-A' included as **Soil & Water Resources Figure 6.** The location of the cross section is shown on **Soil & Water Resources Figure 5A**.

Quaternary Alluvium

Quaternary alluvial fill in the basin consists of Holocene to Pleistocene alluvial fan and fluvial (stream) deposits, as well as lacustrine (lake) and playa (ephemeral lake) deposits (CDWR 2004). These deposits consist of gravel, sand, silt and clay (CDWR 1963). In general, coarser alluvial fan deposits are expected near the valley edges and grade into finer distal fan deposits that interfinger with fine grained lacustrine and playa deposits near the center of the basin. These deposits are typically heterogeneous. Valley axial drainages tend to be more uniform and continuous, and contain a greater proportion of sand and fine gravel. Portions of the basin are also occupied by aeolian (wind blown) sand deposits, but the identified aeolian deposits occur at the ground surface and are of limited thickness. Therefore, they are not believed to be an important water bearing unit.

The Quaternary sediments include the Pleistocene-age Pinto Formation, which consists of coarse fanglomerate (cemented, consolidated or semi-consolidated alluvial fan gravels) containing boulders and lacustrine clay with some interbedded basalt (CDWR 2004). The fanglomerate would likely yield water freely to wells, but the basalt would likely yield only small amounts of water (CDWR 1963). AECOM (2010) did not report the estimated thickness of the Quaternary Alluvium, but suggested the thickness of saturated sediments beneath the site is at least 560 feet and that saturated sediments to a depth of 758 feet consisted of a mixture of fine-grained sands with interbedded silt and clay layers. AECOM (2010) suggested that these sediments are likely to be the older alluvium/Bouse Formation sediments described in Bulletin 91-7 (CDWR 1963).

Pliocene Bouse Formation

The Pliocene Bouse Formation underlies the Quaternary sediments. The Bouse Formation includes a marine to brackish-water estuarine sequence deposited in an arm of the proto-Gulf of California (Metzger 1968; Wilson and Owen-Joyce 1994). This formation has alternatively been interpreted as, or may include, lacustrine sediments deposited in a closed, brackish basin (Stone 2006). The Bouse Formation is widely reported in the Colorado Valley and tributary basins in southeastern California and descriptions of this formation come from occurrences outside of Chuckwalla Valley. It is reported to be composed of a basal limestone (marl) overlain by interbedded clay, silt, sand, and tufa. The top of the Bouse Formation is relatively flat lying with a reported dip of approximately 2 degrees south of Cibola (Metzger et al. 1973). The Bouse Formation in the CVGB is estimated to extend to approximately 1,900 feet bgs (approximately –1,500 feet amsl) beneath the site based on geophysical modeling (see **Soil & Water Resources Figure 4**). These unconsolidated to semi-consolidated sediments are reported to yield several hundred gallons per minute (gpm) to wells perforated in coarse grained units (Wilson and Owen-Joyce 1994).

Miocene Fanglomerate

The Bouse Formation is unconformably underlain by a fanglomerate composed chiefly of angular to subrounded and poorly sorted partially-to fully-cemented pebbles with a sandy matrix (Metzger et al. 1973). The Fanglomerate is likely Miocene-age; however, it may in part be Pliocene-age (Metzger et al. 1973). The Fanglomerate represents composite alluvial fans built from the mountains towards the valley and the debris of the Fanglomerate likely represent a stage in the wearing down of the mountains following the pronounced structural activity that produced the basin and range topography in the area (Metzger et al. 1973). Bedding surfaces generally dip from the mountains towards the basin. The Fanglomerate reportedly dips between 2 and 17 degrees near the mountains due to structural warping (Metzger et al. 1973). The amount of tilting indicates a general decrease in structural movements since its deposition (Metzger et al. 1973). The Fanglomerate is estimated to extend to approximately 2,600 feet bgs (-2,000 feet amsl) beneath the site based on geophysical modeling by Worley-Parsons (2009).

Bedrock

Bedrock beneath the site consists of metamorphic and igneous intrusive rocks of pre-Tertiary age that form the basement complex (CDWR 1963). In some areas of the basin, volcanic rocks of Tertiary age overlie the basement complex (CDWR 1963). These rocks are considered nonwater bearing. The bedrock topography in the study area as interpreted by modeling of Bouger gravity data obtained from USGS is illustrated in **Soil & Water Resources Figure 4** The methods used to model the bedrock topography are discussed in more detail in Genesis Solar Energy Project Application for Certification Appendix D (Worley-Parsons 2009).

Groundwater Occurrence and Movement

In general, groundwater flow in the basin is south-southeastward (**Soil & Water Resources Figure 7**). Groundwater flow is directed southward from the basin's boundary with the Cadiz Valley Basin and east-southeastward from its boundary with the Pinto Valley Basin, toward the eastern basin boundary where it flows into the adjacent Palo Verde Mesa Basin (Steinemann 1989). The groundwater gradient is the steepest in the western half of the basin and is nearly flat in the central portion of the basin (CDWR 1963). Near Ford Dry Lake and east of Ford Dry Lake the gradient becomes steeper as groundwater approaches the narrows in the southeast portion of the basin (Steinemann 1989; DWR 1963).

Groundwater levels exceed 500 feet amsl in the western portions of the basin and fall to less than 275 feet amsl near the eastern end of the basin in the narrows between the Mule and McCoy Mountains (Steinemann 1989). Near Palen Lake, groundwater occurs near the ground surface, resulting in groundwater discharge by evapotranspiration at the land surface. Near Ford Dry Lake, groundwater is reported at depths of 50 feet below ground surface. Beneath the project site, groundwater occurs at depths of approximately 180-200 feet bgs (approximately 400 feet amsl) based on-site-specific investigation (Solar Millennium 2009a).

The DWR reports that groundwater levels in the basin are generally stable (CDWR 2004). **Soil & Water Resources Figure 8** shows hydrographs for selected wells within the Chuckwalla Valley from 1958 to 2009. The wells selected to present the hydrograph data were chosen to present the most complete set of historic water level elevation data across the Chuckwalla Valley. The hydrographs show that the water level has been generally stable over the last 40 years in the central and eastern part of the basin. This area includes the project site. The hydrograph for well 7/20-18H1 in the eastern part of the basin shows a decrease in water level elevation occurred between 1985 and 1990. This well is associated with the Chuckwalla and Ironwood Prisons and the decline in water level is likely due to increased water use at the prisons. The hydrograph for well Township7S Range 18E-14H1 shows a slight (approximately 20 foot) increase in the water level between 1983 and 1992. This well and the three other wells at this location are associated with agriculture activities and the water level increase is likely due to the fallowing of the land.

The hydrographs for wells in the Desert Center area along Highway 177 show local effects of water level decline, attributable to increased agricultural pumping beginning in the early 1980s and ending in the mid 1980s. GEI estimated groundwater pumping in 1986 was about 20,000 afy, significantly up from the 1963 estimate of 9,100 afy from the DWR. Basin wide pumping declined rapidly since 1986 with recent estimates of about 6,000 afy.

The inconsistency in groundwater level measurements makes it difficult to establish a specific year for the groundwater decline to have started. However, the hydrograph for well 4/16-32M1 suggests the decline started in 1980 and the water level had dropped approximately 50 feet at the time of the last water level measurement. The hydrograph for well 5/15-12N1, located approximately four miles to the southwest of well 4/16-32M1, shows only a small decline (approximately five feet) in the water table elevation. The water level readings in well 5/15-12N1 suggest the water level, at this well, has recovered to pre-pumping levels. The data presented in the hydrographs suggest that pumping around Desert Center induced a local cone of depression in that area that did not extend eastward into the area of the project site. The differential response and recovery to pumping in this area would suggest some compartmentalization of the aquifer system that is not unexpected since it is comprised of interconnected and isolated alluvial fan deposits.

Aquifer Characteristics

The basin fill sediments within the CVGB include three aquifers: the alluvium, the Bouse Formation, and the Fanglomerate. Groundwater in the alluvium likely occurs under unconfined conditions but could locally be semi-confined. Groundwater in the Bouse Formation and the Fanglomerate was reported to be under semi-confined to confined conditions based on stratigraphic data and storativity values derived from aquifer pumping tests near the Genesis project site east of the project (Worley-Parsons 2009). **Soil & Water Resources Table 11** summarizes the reported and estimated aquifer properties for these aquifers based on data from specific capacity tests and aquifer pumping tests performed on wells in the CVGB.

Soil & Water Resources Table 11
Aquifer Characteristics

Geologic Unit	Well ID	Well Depth	Specific Capacity (gpm/ft)	Transmissivity (gpd/ft)	Hydraulic Conductivity (ft day)	Storativity	Basis

Transmissivity from Specific Capacity Tests calculation by multiplying value by 2,000. for confined aquifers and by 1,500 for unconfined aquifers (Driscoll 1986).

Groundwater Quality

Groundwater quality varies markedly in the basin. Groundwater in the western portion of the basin near Desert Center generally contains lower concentrations of total dissolved solids (TDS) than groundwater in the eastern, down gradient portion of the basin near Ford Dry Lake (Steinemann 1989). Groundwater to the south and west of Palen Lake is typically sodium chloride to sodium sulfate-chloride in character (CDWR 2004). The detected concentrations of TDS in the basin range from 274 mg/L to 8,150 mg/L with an average concentration of 2,100 mg/L (Steinemann 1989). In general, the groundwater in the basin has concentrations of sulfate, chloride, fluoride, and dissolved solids too high for domestic use and concentrations of sodium, boron and dissolved solids too high for irrigation use (CDWR 2004). Several of the wells sampled in the basin contain high levels of fluoride and boron.

Groundwater Wells in Proximity to the Proposed modified project

A total of 88 water supply wells were identified in online databases in the CVGB (Solar Millennium 2009a – Appendix J). A field survey was conducted by AECOM (Solar Millennium 2009a) in July 2009 to identify the well location, confirm operational status, and estimate the use within the basin. The wells were categorized as either domestic, industrial, agricultural or municipal wells based on land use or information provided by the property owner.

A total of 15 wells were identified, most of which supported historic agricultural operations and many of which have been discontinued. Available information for water supply wells located within a one-mile radius of the Project site are summarized on **Soil & Water Resources Table 12** and shown on **Soil & Water Resources Figure 9**.

Soil & Water Resources Table 12
Summary of Groundwater Quality Data[1],[2]
(all values reported in mg/L unless otherwise indicated)[3]

Analyte	Well 5/17-33N1 (2009)	Well 5/17-20F1 (May 1957)	Well 5/17-30F1 (January 1960)	Well 5/17-30P1 (October 1958)	All Chuckwalla Valley Wells [1]
Arsenic	0.0157	—	—	—	—

Sulfate	380	241	155	89	9–1,110
Total Hardness ($CaCO_3$)	830	150	75	38	3–2,300
TDS	1,010	803	695	783	274–12,300
pH (units)	—	7.4	8.1	8	7–8.7

Notes:
1 - Geochemical data for all wells within the Chuckwalla Groundwater Basin from available information in online databases and historic reports is provided in Solar Millennium 2009a.
2 - Metals data reported from the unfiltered ("total") sample
3 - mg/L = milligrams per liter; ND – not detected at the practical quantitation limit
4 - Nitrate as Nitrogen.

SURFACE WATER HYDROLOGY

The site is located within the Colorado River Basin, Chuckwalla Valley Drainage Basin. There are no perennial streams in Chuckwalla Valley. Chuckwalla Valley is an internally drained basin, and all surface water flows to Palen Dry Lake in the western portion of the valley and Ford Dry Lake in the eastern portion of the valley. Palen Dry Lake is a "wet playa" with significant shallow groundwater discharge at the ground surface by evaporation; whereas, Ford Dry Lake is a "dry playa," with groundwater occurring well below the ground surface. Palen Dry Lake is located in the central portion of Chuckwalla Valley about 1 mile north of the proposed plant location.

The only perennial surface water resources in the eastern portion of Chuckwalla Valley are McCoy Spring, at the foot of the McCoy Mountains approximately 19 miles northeast of the site, and Chuckwalla Spring, approximately 16 miles south of the site at the foot of the Chuckwalla Mountains.

Off-site storm water flows impacting the project site are from a large watershed area to the west and north of the site which covers approximately 44 square miles. Federal Emergency Management Agency (FEMA) flood insurance rate maps have not been prepared for the project site or surrounding lands and the project does not lie within a federally mapped floodplain. The upstream extents of the contributing watersheds extend into the Chuckwalla Mountains to the southwest. The extent of an approximate sub-basin boundaries of the overall watershed impacting the project were delineated utilizing a combination of USGS 7.5 minute quadrangle sheets and site specific aerial topography.

The overall watershed boundaries sub-basin delineations, as well as the 100-year peak discharges for each sub-basin are shown on **Soil & Water Resources Figure 10**. The project owner calculated existing (pre-construction) peak discharges for each sub-basin using the hydrograph package HEC-1 and followed the guidelines presented in the *Riverside County Flood Control and Water Conservation District Hydrology Manual (Riverside County Manual),* and are summarized in **Soil & Water Resources Table 13.**

Soil & Water Resources Table 13
Summary of Offsite Upstream Peak Flows

Upstream Flows	Tributary Area (square miles)	24-hour 100-year (cubic-feet/second)
Copa Ditch	30.77	8,262
Aztec Ditch	30.8	6,490
Tarantula Ditch	35.88	1,466
Sutro Ditch	13.04	3,193

Dry Washes

There are no perennial streams in the Palen Dry Lake or Ford Dry Lake watersheds which impact the project site. The vast majority of the time, the area is dry and devoid of any surface flow. Water runoff occurs only in response to infrequent intense rain storms. There are approximately a hundred minor washes that cross the site from southwest to northeast, draining the area downstream of I-10 towards Palen Dry Lake. Many of these channels do not reach the dry lake, but fade out on the vegetated sand dune surface. These channels are typically very subtle, with a width of 2-10 feet and a depth of 3-9 inches. They are found approximately every 100 feet when traversing across the project site perpendicular to the predominant flow direction which is to the northeast.

There are two more significant ephemeral wash complexes that cross the site from southwest to northeast, draining the area downstream of I-10 towards Palen Dry Lake. Both washes were traceable from the western project boundary to Palen Dry Lake. These major washes are observed as complexes of braided channels, with each channel being approximately 10-50 feet wide. The wash complexes widen out from their constriction at I-10 and are approximately 1,500 feet wide after approximately a mile, after which they become very dispersed, lose definition and resemble minor washes. Within a mile of I-10, the major washes have created sandy zones approximately 1,500 feet wide on the less sandy alluvial gravel or thin sand sheets.

Springs, Seeps and Playa Lakes

One spring is listed in the CVGB in the vicinity of where the Project site is located, according to the National Water Information System (NWIS) database of Water Resources of the United States, which is maintained by the USGS (http://wdr.water.usgs.gov/nwisqmap/). This spring (called Corn Spring) is also shown on a geologic map of the area (CDMG 1967). Corn Spring is approximately five to six miles southwest of the project site in the center of the Chuckwalla Mountains. The spring discharges into Corn Spring Wash, an ephemeral dry wash where surface water flows towards the northeast and onto the project site. Corn Spring appears to derive its water from precipitation falling onto the Chuckwalla Mountains, and movement of groundwater under pressure along an historic fault that bisects the mountains.

According to the NWIS database, seeps and surface discharge/outfall (along with streams, lakes, wetlands, and diversions) are categorized as “surface water sites” and four sites are located in the CVGB. One of the four locations is the aforementioned Corn Spring Wash, while two other sites are located near the northern edge of the Chuckwalla Mountains approximately eight and 13 miles west of the project site. Water in these three sites appear to originate from infiltration of precipitation that falls on the Chuckwalla Mountains as all three sites are located either within the Chuckwalla Mountains or are less than one mile downslope from the Chuckwalla Mountains.

The fourth “surface water site” listed in the NWIS database for the CVGB is Coxcomb Wash, located approximately eight miles northwest of the project site. Coxcomb Wash is an ephemeral dry wash that flows southeastward from the Coxcomb Mountains. As a result, groundwater extracted from the project site would not affect the flow of water in Coxcomb Wash. The locations of Corn Spring and other “surface water sites” identified in the NWIS database and through the several other data sources are shown on **Soil & Water Resources Figure 11**. The sites are listed on **Soil & Water Resources Table 14**.

Soil & Water Resources Table 14
Springs and Surface Water Sites in Chuckwalla Valley within Nine Miles of the Project Site

Site No.	Location Number	Location Name	Type	Distance from Project (miles)

8	WHIPs ID S-375	Long Tank Tenaja	Pond	8.9
9	N/A	Desert Center Sewer Pond	Pond	8.5

Source: AECOM 2010

Tenajas are defined as seasonal precipitation-fed or ephemeral stream basins which can hold significant quantities of water. By definition (AGI 2005), ephemeral streams are a stream or reach of a stream that “flows briefly only in direct response to precipitation in the immediate locality and whose channel is at all times above the water table.” Two tenaja locations were located in the study area and are noted, but would not be affected by groundwater extraction. Similarly, numerous wildlife water guzzlers (devices used to collect and store water derived from snow and/or rainwater for later use by wildlife in the area) for small and large game are identified, but these man-made structures are designed to store precipitation and would not be affected by groundwater pumping.

Storm Water Flow

Storm water flow across and adjacent to the project occurs in a network of generally shallow and moderately expressed alluvial channels, and during larger events, as more widespread sheetflow. In general, the channels become shallower and less defined the further they are from the Chuckwalla Mountains. I-10 is an important local control on drainage across the project site, as it intercepts a large number of ephemeral washes draining towards the site from upstream (southwest) of the interstate. These channels are captured by a series of berms and interceptor channels that run parallel with I-10, periodically passing the collected water under I-10 at bridges and creating larger washes that pass under the interstate. There are three distinct locations where this occurs upstream of the project: Copa Ditch, Aztec Ditch, and Tarantula Ditch. These flows are relatively concentrated near the southern project boundary, but quickly disperse into a network of smaller and less defined channels under existing conditions (see **Soil & Water Resources Figure 12**).

SURFACE AND GROUNDWATER BENEFICIAL USES

The Basin Plan for the Colorado River Basin Regional Water Quality Control Board (CRBRWQCB) establishes water quality objectives, including narrative and numerical standards that protect the beneficial uses of surface and ground waters in the region. The Basin Plan describes implementation plans and other control measures designed to ensure compliance with statewide plans and policies and provide comprehensive water quality planning.

Beneficial water uses are of two types—consumptive and non-consumptive. Consumptive uses are those normally associated with people's activities, primarily municipal, industrial and irrigation uses that consume water and cause corresponding reduction and/or depletion of water supply. Non-consumptive uses include swimming, boating, waterskiing, fishing, hydropower generation, and other uses that do not significantly deplete water supplies.

1. Past or Historical Beneficial Uses
    a. Historical beneficial uses of water within the Colorado River Basin Region have largely been associated with irrigated agriculture and mining. Industrial use of water has become increasingly important in the Region, particularly in the agricultural areas.
2. Present Beneficial Uses
    a. Agricultural use is the predominant beneficial use of water in the Colorado River Basin Region, with the major irrigated acreage being located in the Coachella, Imperial and Palo Verde Valleys. The second in quantity of usage is the use of water for municipal and industrial purposes. The third major category of beneficial use, recreational use of surface waters, represents another important segment of the Region's economy.
3. Sources of Drinking Water Policy
    a. All surface and ground waters are considered to be suitable, or potentially suitable, for municipal or domestic water supply with the exception of:
        i. Surface and ground waters where: the TDS exceed 3,000 mg/L, and it is not reasonably expected by the regional water board to supply a public water system, or
        ii. There is contamination, either by natural process or by human activity, that cannot be treated for domestic use using either management practices or best economically achievable treatment practices, or
        iii. The water source does not provide sufficient water to supply a single well capable of producing an average, sustained yield of 200 gallons per day.

Existing uses of waters from springs in the Colorado River Basin include the Box Spring, Crystal Spring, Old Woman Spring, Cove Spring, Mitchell Caverns Spring, Bonanza Spring, Agua Caliente Spring, Kleinfelter Spring, Von Trigger Spring, Malpais Spring, and Sunflower Spring. Based on a review of available information included in the USGS NWIS database, USGS quadrangle maps, and data provided by the BLM, none of these springs are within the area that would be influenced by the project. Existing uses of water from springs in the Colorado River Basin include Bousic Spring, Veale Spring, Nett Spring, Gordon Spring, and Arctic Canyon Spring. None of these springs are within the area that would be influenced by the project.

Water quality objectives are established for the reasonable protection of beneficial uses of water or the prevention of nuisance within a specific area.

1) General Surface Water Objectives (CRBRWQCB)

   a. Aesthetic Qualities - All waters shall be free from substance attributable to wastewater of domestic or industrial origin or other discharges which adversely affect beneficial uses not limited to: setting to form objectionable deposits; floating as debris, scum, grease, oil, wax, or other matter that may cause nuisances; and producing objectionable color, odor, taste, or turbidity.

   b. Tainting Substances – Waters shall be free of unnatural materials which individually or in combination produce undesirable flavors in the edible portions of aquatic organisms.

   c. Toxicity – All waters shall be maintained free of toxic substances in concentrations which are toxic to, or which produce detrimental physiological responses in human, plant, animal, or indigenous aquatic life. Compliance with this objective will be determined by use of indicator organisms, analyses of species diversity, population density, growth anomalies, 96-hour bioassay or bioassays of appropriate duration or other appropriate methods as specified by the CRBRWQCB. Effluent limits based upon bioassays of effluent will be prescribed where appropriate, additional numerical receiving water objectives for specific toxicants will be established as sufficient data to become available, and source control of toxic substances will be encouraged. The survival of aquatic life in surface waters subjected to a waste discharge or other controllable water quality factors, shall not be less than that for the same water body in areas unaffected by the waste discharge, or other control water which is consistent with the requirements for "experimental water" as described in Standards Methods for the Examination of Water and Wastewater.

   d. Temperature – temperature shall not be altered

   e. pH – shall range from 6.0 to 9.0

   f. Dissolved Oxygen – shall not be reduced below the following minimum levels at any time: warm – 5.0 mg/L, cold – 8.0 mg/L, and warm and cold – 8.0mg/L

g. Total Dissolved Solids – discharges of wastes or wastewater shall not increase the total dissolved solids content of receiving waters, unless it can be demonstrated to the satisfaction of the Regional Board that such an increase in total dissolved solids does not adversely affect beneficial uses.

h. Bacteria – The geometric mean of the indicated bacterial densities should not exceed one or the other of the following: E. coli – 630 colonies (col) per 100 ml and enterococci – 165 col per 100 ml. Nor shall any sample exceed one other following maximum allowable: E. coli 2000 col per 100 ml and enterococci 500 col per 100 ml.

Any discharge, except from agricultural activities, shall not cause concentration of total dissolved solids in surface waters to exceed the limits in **SOIL & WATER RESOURCES Table 15**.

Soil & Water Resources Table 15
Surface Water TDS Limits

Location	TDS (mg/L)	
	Annual Average	Maximum
Coachella Valley Drains	2,000	2,500
Palo Verde Valley Drains	2,000	2,500

2) General Groundwater Objectives: Establishment of numerical objectives for groundwater involves complex considerations and it is acknowledged that the quality of groundwater varies significantly throughout the CVGB and varies with depth. It is the CRBRWQCB's goal to maintain the existing quality of non-degraded groundwater basins and to minimize the quantities of contaminants reaching any groundwater basin.

   a. Groundwater designated for domestic or municipal supply shall not contain taste or odor producing substances

   b. Groundwater designated for domestic or municipal supply shall not contain coliform organisms in excess of limits specified in the regulations.

   c. Groundwater designated for domestic or municipal supply shall not contain concentrations of chemical constituents in excess of the limits specified in California Code of Regulations, Title 22 regulations.

   d. Discharges of water softeners regeneration brines, other mineralized wastes, and toxic wastes to disposal facilities which ultimately discharge in areas where such waste can percolate to ground waters useable for domestic and municipal purposes, are prohibited.

Wastewater reclamation and reuse is encouraged, however, such use must meet applicable water quality standards.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

This section provides an evaluation of the expected direct, indirect, and cumulative impacts to soil and water resources that could be caused by construction, operation, and maintenance of the PSEGS. Staff's analysis consists of a description of the potentially significant impacts, gathering data related to construction and operation of the project, then reaching a conclusion to determine whether or not the project presents potentially significant impacts. If staff determines there is a significant impact, then staff evaluates the approved PSPP mitigation contained in the Commission Decision (CEC 2010f) for sufficiency and staff may or may not recommend additional or entirely different mitigation measures that are potentially more effective than those in the Commission Decision or proposed by the project owner. Mitigation is designed to reduce the effects of potentially significant PSEGS impacts to a level that is less than significant.

Potential impacts on water resources during construction and operation include, soil erosion, geomorphology, groundwater basin balance, groundwater levels, groundwater quality, surface water hydrology, and surface water quality impacts.

SOIL EROSION

The modified project proposes a substantial reduction in potential soil loss compared to the approved project. The heliostat technology would not require an entirely flat surface that was needed for solar trough technology, so extensive grading would be avoided. The modified project would reduce the project footprint from 4,366 acres to 3,794 acres, a difference of 572 acres. The total earthwork proposed by the modified project would be prominently less at 213,000 cubic yards, which is roughly five percent of the approved project's 4,500,000 cubic yards of total earthwork. Although these differences would inherently reduce the grading impacts compared to the approved project, the substantial changes in earthwork could potentially create issues that were not analyzed during assessment of the approved project. Therefore, the following soil erosion discussion is entirely independent of the analysis found in the Revised Staff Assessment for PSPP.

Construction

Construction of the project is scheduled to last 33 months. Soil losses would be created by construction and grading activities that would expose and disturb the soil and leave soil particles vulnerable to detachment by wind and water. Soil erosion results in the loss of topsoil and increases in sediment loading to nearby water resources. In the absence of proper BMPs, earthwork could cause significant fugitive dust and erosion.

The magnitude, extent, and duration of those impacts would depend on several factors, including weather patterns in the vicinity of the PSEGS site, the types of soil that could be affected, and the method, duration, and time of year of construction activities. Prolonged periods of precipitation, or high intensity and short duration runoff events coupled with earth disturbance activities could result in accelerated onsite erosion. In addition, high winds during grading and excavation activities could cause wind borne erosion leading to increased particulate emissions that adversely impact air quality. The implementation of appropriate erosion control measures would help conserve soil resources, maintain water quality, prevent accelerated soil loss, and protect air quality.

Power Plant Sites, Common Area, and Laydown Area

The potential for erosion by water during construction is expected to increase as a result of the loss of vegetative cover, and increased local sediment transport through creation of localized gullies and rills on newly graded areas. The project owner submitted a Preliminary Draft Construction DESCP/SWPPP (Palen 2013e) that lists standard BMPs applicable to PSEGS construction activities along with drawings (Palen 2013g) that show locations of specific BMPs at each power block, the common area, and temporary construction laydown area. In addition, the DESCP identifies specific measures to reduce water-related erosion including:

- Temporary erosion control measures would be implemented on active and non-active disturbed areas prior to and at regular intervals throughout the defined rainy season, and year-round prior to storm events;
- Erosion in concentrated flow paths would be controlled by lining channels with a non-erodible material such as compacted riprap, geosynthetic matting, or engineered vegetation;
- Diversion berms (for example, earth dikes) or drainage swales would be used, as needed, to redirect storm water run-on or onsite storm water flow around critical facilities or away from disturbed soil areas and stockpiles;
- Disturbed areas would be stabilized with effective soil cover (such as aggregate, paving, or vegetation) as soon as feasible after construction or disturbance is complete and no later than 14 days after construction or disturbance in that portion of the site has temporarily or permanently ceased;
- Sediment controls would be implemented at the draining perimeter of disturbed soil areas, at the toe of slopes, and at outfall areas; and
- Stone filters and check dams would be strategically placed, as needed, throughout the project site to provide areas for sediment deposition and to promote the sheet flow of storm water prior to leaving the project site boundary. Where available, native materials (rock and gravel) would be used for the construction of the stone filter and check dams. Stone filters and check dams are not intended to alter drainage patterns but to minimize soil erosion and promote sheet flow.

The Preliminary Draft DESCP also includes a Monitoring and Reporting Program/Construction Site Monitoring Program to ensure performance standards and to monitor the effectiveness of BMPs.

Solar Fields – Heliostats and Roads

The Preliminary Draft DESCP states that each area of the PSEGS project would be designed to provide the minimum requirements for access of installation equipment and materials. Most of the natural drainage features would be maintained and any grading required would be designed to promote sheet flow where possible. Areas disturbed by grading and other ground disturbance would be protected from erosion by implementation of appropriate BMPs. Some of the measures listed include:

- Existing vegetation would be preserved when feasible. Vegetation would be cut to a height that would not interfere with construction and operation of the heliostat fields, instead of clearing or grading the entire field;
- Clearing and grading activities would be restricted to areas where foundations, drainage facilities, and all-weather roads must be placed;
- Areas compacted during construction activities would be restored, as appropriate, to approximate preconstruction compaction levels to minimize the opportunity for any increase in surface runoff; and
- Effective sediment perimeter controls would be established and maintained at locations where runoff discharges offsite.

Wind Erosion

The Preliminary Draft DESCP also includes standard BMPs for Wind Erosion Control. The following practices were listed to minimize the loss of wind-blown soil from the site:

- Disturbed soil areas of the project site would be watered regularly to control dust and to maintain optimum moisture levels for compaction as needed, but to avoid runoff, the areas would not be watered excessively. Sediment controls may be used at the edges of these areas as necessary to minimize sediment discharge;
- Areas of high erosion may require application of an approved palliative to reduce dust and prevent excess moisture on the road which may attract tortoises;
- At each structure site, the disturbed soil would be watered to form a crust following completion of construction in that location; and
- The construction site would post visible speed limit signs to prevent vehicles from traveling at excessive speeds.

Staff reviewed the Preliminary Draft DESCP and agrees that BMPs during construction would reduce or avoid impacts to soil from erosion. To protect surface waters, standardized storm water and soil erosion BMP[11] have been determined by the California State Water Resources Control Board (SWRCB) and Regional Water Quality Control Boards (RWQCBs) to be the most effective, practical means of preventing or reducing pollution from nonpoint sources. The conceptual plans for erosion control during construction appear reasonable, but there are additional elements that should be incorporated into the final DESCP that would be developed as required in Condition of Certification **SOIL&WATER-1**. The DESCP should reflect the most recent design plans of the proposed PSEGS project. If during the Energy Commission's amendment process any changes to the modified project are proposed, any adjustments that would alter the erosion control drawings, change the BMP strategy, or result in revised hydrology or hydraulic calculations should be reflected and addressed in an updated DESCP.

[11] BMPs can be classified as "structural" (i.e., devices installed or constructed on a site) or "non-structural" (procedures, such as modified landscaping practices). There are a variety of BMPs available, depending on pollutant removal capabilities.

Staff believes that compliance with an approved DESCP accordance with Condition of Certification **SOIL&WATER-1** would reduce the impacts of soil erosion during construction. In addition, the project activities require that it be covered under the federal General Construction Permit (SWRCB Order No. 2009-0009-DWQ), which requires a construction SWPPP. Also, conditions of certification in the **AIR QUALITY** section of this FSA require a construction mitigation plan to prevent significant impacts from fugitive dust and wind erosion during construction. With the implementation of BMPs and associated monitoring activities included in the approved DESCP and SWPPP, impacts on soil would be expected to be less than significant during construction of the proposed PSEGS project.

Operation

Soil losses would be ongoing after the construction of the PSEGS project. Areas disturbed during the construction phase are subject to potential erosion during the operational life of the proposed project. PSEGS would be designed for an operating life of 25 to 30 years.

Onsite Erosion

The estimated total area of land grading and excavation during construction of the PSEGS project would be about 752 acres,[12] as shown in **Soil & Water Resources Table 2**. After project completion, the temporary parking and construction laydown areas would be restored and about 25 acres would become impervious due to the addition of concrete foundations and asphalt paving. The balance of the previously disturbed area, roughly 730 acres, would be susceptible to potential erosion during the operational life of the proposed project. Furthermore, the addition of impervious surfaces to an area previously undeveloped would increase velocities of storm water runoff (see “Surface Water Hydrology” discussion below), which would increase the erosion potential of open soil areas.

The project owner submitted a Preliminary Draft DESCP/SWPPP (Palen 2013e) that states permanent erosion control measures would reduce potential soil related impacts, including gravel, landscaping, and engineering drainage channels. These would be stabilized areas with very little or essentially no risk of erosion. In addition, relatively small rock filters and local diversion berms through the heliostat fields may be installed as required to discourage water from concentrating and to maintain sheet flow. These all would serve to prevent wind and water erosion and maintain some water infiltration capacity of the soil.

Staff agrees that implementation and maintenance of permanent BMPs during operations would reduce or avoid impacts to onsite soil from erosion. The Preliminary Draft DESCP is reasonable in concept; however, it does not sufficiently discuss post construction measures for erosion and sediment control. The document should address exposed soil treatments proposed during operation of the project for both road and non-road surfaces, as described in item H of Condition of Certification **SOIL&WATER-1**. A maintenance schedule should include post-construction maintenance of BMPs applied

[12] This total does not include the surface areas of all the heliostat mirrors because all-terrain vehicles would install pylons and mount heliostat assembles. No grading would be required.

to disturbed areas following construction. These should also reflect requirements regarding ground disturbing activities and erosion control measures specified in Conditions of Certification **BIO-8**.

Staff believes that compliance with Condition of Certification **SOIL&WATER-1** requiring the project owner to develop and implement an approved DESCP would reduce the impacts of soil erosion during operation of the modified project. Additionally, conditions of certification in the **AIR QUALITY** section of this FSA would prevent significant impacts from fugitive dust during operations.

Although modeling and calculations can be used to estimate post-construction flows and provide a basis for structural design parameters, alluvial flows are very complex. Flood flows from the mountains are initially confined in incised channels, but at the site the flood flows are broadly distributed (known as sheet flow) and less confined and can take random paths across the fan. Predicted flow depths and velocities have a potential uncertainty because they do not account for the dynamics of erosion and sedimentation which carry and deposit sediments at various locations along the margin of the alluvial fan where the site is located. Where obstructions such as heliostats and fences are encountered, flows can have erosive effects which could undermine their stability. The consequences of flash flood damage or modified sedimentation and erosion rates may be significant. Staff proposes Condition of Certification **SOIL&WATER-20** requiring a Storm Water Damage Monitoring and Response Plan to reduce these potential impacts.

Offsite Erosion

The project's addition of impervious surfaces could also increase velocities of storm water runoff leaving its boundaries, possibly increasing the potential to erode offsite areas downstream of the project. To address the potential significant offsite erosion from storm damage, staff proposes Condition of Certification **SOIL&WATER-20** requiring a Storm Water Damage Monitoring and Response Plan to reduce these potential impacts in three ways:

1. Establish an ongoing maintenance plan to ensure all storm water management measures are functioning properly, through periodic inspection before the first seasonal storms and after each storm event throughout the year;

2. Establish and implement a response plan after every occurrence of damage (from a storm event or other cause) to clean up and repair damage; and

3. Develop and implement a process to monitor incidents and propose modifications and/or improvements to address ongoing issues.

Staff believes that compliance with an approved DESCP in accordance with Condition of Certification **SOIL&WATER-1** and an approved Storm Water Monitoring and Response Plan in accordance with Condition of Certification **SOIL&WATER-20** would reduce the impacts of soil offsite erosion during operation of the proposed project.

Mitigation

Construction and operation of the modified project could result in significant impacts related to water erosion of soils. Implementation of BMPs and Conditions of Certification would reduce the impacts to insignificant. Implementation of Conditions of Certification **SOIL&WATER-1** and **SOIL&WATER-20**, in addition to conditions of certification required in the **AIR QUALITY RESOURCES** and **BIOLOGICAL RESOURCES** sections of this FSA would ensure there would be no potential for impacts to soils related to water erosion.

Geomorphology

The combined sand corridor is a regionally significant geomorphic feature that transports sand downwind along the valley and to the Colorado River. The approved project would have intruded into the Chuckwalla Valley sand transport corridor by more than a mile, cutting its width in half and that would have created a "sand shadow" downwind – an area of current dune habitat where fine sand would be eroded downwind but not replaced from upwind, leading to loss of the sand dunes. Previous studies have shown that such sand shadows result in deflation, substrate coarsening and potential loss of Mojave Fringe Toad Lizard (MFTL) habitat.

The project owner has proposed as part of the modified project to eliminate the approved project's 30-foot tall wind fence which contributed to disruption of the sand transport corridor. However, the modified project would still have a project boundary fence (security fence) and desert tortoise exclusion fencing. Any fence design could impede sand transport and result in downwind impacts to sand dune habitat. In addition, sand that would have been transported across the project footprint from upwind would also be potentially cut off by storm drainage channels and above ground infrastructure that are proposed as part of the modified project (Palen 2013r §19). A complete analysis of indirect impacts for the modified project is included in the **BIOLOGICAL RESOURCES** section of this FSA.

GROUNDWATER BASIN BALANCE

Because the modified PSEGS project would use a reduced amount of water during both construction and operation activities with the same proposed groundwater supply system as the approved PSPP project, staff believes that this does not constitute a project change from the approved project. Therefore, the following groundwater basin balance discussion has been included in this analysis verbatim from the Revised Staff Assessment for PSPP (CEC 2010c §C.9). Some minor edits were made for clarification.

Staff evaluated whether the amount of groundwater used for both construction and operations would place the groundwater basin into overdraft[13]. For purposes of impact analysis, it is assumed that any withdrawals that exceed the average natural recharge and exceeds a significant percentage of the total amount of groundwater in storage would be a significant impact. The following discussion presents an analysis of the potential for overdraft and significant depletion of groundwater in storage to occur.

---

[13] Groundwater overdraft is "the condition of a groundwater basin in which the amount of water withdrawn by pumping exceeds the amount of water that recharges the basin over a period of years during which water supply conditions approximate average conditions." (CDWR 1998).

Construction and Operation

Compared to the approved PSPP project, the modified PSEGS project would reduce water use both during construction (from 5,750 af to 1,130 af) and during operation (from 300 afy to 201 afy). As a result, the overall water use of PSEGS could be roughly half that of PSPP (7,160 af compared to 14,750 af). Because this reduction in groundwater use would reduce the potential effects on groundwater basin balance, the conditions of certification in the Commission Decision (CEC 2010f), which fully mitigated the PSPP groundwater use, would also fully mitigate PSEGS groundwater use. Staff included the following PSPP groundwater analysis as an overly conservative scenario of groundwater basin balance impacts.

A comparison was made between the average annual basin budget with the PSPP project's anticipated water production requirements. **Soil & Water Resources Table 16** presents the anticipated water requirements along with the average annual basin budget for the PSPP's 39-month construction period. Currently, the CVGB balance is positive by approximately 2,608 afy whereby inflow (approximately 13,719 afy) to the basin is slightly greater than estimated outflows (approximately 11,111 afy) to the basin. Approximately 400 afy is attributed to subsurface outflow to the adjacent Palo Verde Mesa Groundwater Basin.

Soil & Water Resources Table 16
Estimated Change to Chuckwalla Valley Groundwater Basin Budget
(Average Year Conditions)

Project Component	Years	Annual Basin Budget Balance	PSPP Requirements (afy)	Net Budget Balance (afy)
Construction	1-3	2,608	1,917	691
Operations	4-33	2,608	300	3,050

Note: See Soil & Water Resources Table 8 for Groundwater Basin Budget

It is anticipated that groundwater extraction during PSPP construction (~1,917 afy) and operation (~300 afy) would not significantly impact the CVGB balance as the ~1,917 afy during construction and the 300 afy during operations would not exceed the positive yearly balance of 2,608 afy. Therefore, the anticipated groundwater extracted during PSEGS construction (~400 afy) and operation (~201 afy) would not significantly impact the CVGB balance.

The project's pumping could have an effect on the adjacent Palo Verde Mesa Groundwater Basin by inducing flows from the Colorado River into that basin. However, given the location of the project, the anticipated annual project water requirements, staff does not anticipate that the project would have a significant impact on the adjacent (Palo Verde Mesa) groundwater basin.

Solar Millennium, the PSPP project owner, did not provide an analysis of the proportion of water originating from storage, from natural recharge and/or the Colorado River underflow. However, water in the Colorado River is fully appropriated and according to a U.S. Supreme Court Decision (issued in *State of Arizona v. State of California* (2006) 547 U.S. 150, 126 S.Ct. 1543 "[c]onsumptive use from the mainstream within a State shall include all consumptive uses of water of the mainstream, including water drawn from the mainstream by underground pumping.") The mainstream was indicated as "the mainstream of the Colorado River downstream from Lee Ferry within the United States, including the reservoirs thereon." The Supreme Court went on to state that the State of California is enjoined "from diverting or purporting to authorize the diversion of water from the mainstream the diversion of which has not been authorized by the United States for use in the respective States; provided, however, that no party named in this Article and no other user of water in said States shall divert or purport to authorize the diversion of water from the mainstream the diversion of which has not been authorized by the United States for its particular use."

The USGS has indicated that the Palo Verde Mesa Groundwater Basin (PVMGB) and the CVGB lie within a basin tributary to the Colorado River and that wells drawing groundwater could be considered withdrawing water from the Colorado River Aquifer (Wilson et al. 1994). In addition, using the groundwater model developed by Worley-Parsons (2009) suggests that the subsurface flow from CVGB to PVMGB could be reduced as much as 32 afy after 33 years of construction and operation of the approved PSPP project. The reduction in flow to the PVMGB could likely increase flow from the Colorado River into the PVMGB. Staff believes the project owner should be required to replace the quantity of water contributed by the Colorado River from the project's proposed groundwater extraction.

Use of Colorado River water must meet requirements of the United States Bureau of Reclamation (USBR). In 2008, USBR proposed a rule that specified a method to determine whether any particular well is drawing water from the river aquifer, thus requiring an entitlement from USBR. The proposed rule was later withdrawn by USBR with no anticipated date of being promulgated.[14] Condition of Certification **SOIL&WATER-14** requires development of a Water Supply Plan that includes water conservation projects such as payment for irrigation improvements in Palo Verde Irrigation District, purchase of water rights within the Colorado River Basin that would be held in reserve, and/or participation in BLM's Tamarisk Removal Program. To support the fact that water conservation measures are available, an example of a Tamarisk Removal Program is provided below.

The purpose of a Tamarisk Removal Program is to provide for an additional mechanism to mitigate for potential impacts to groundwater supply as a result of water use by the project. This component not only provides benefits to the groundwater system (and replacement of Colorado River water), but also provides a potential biological benefit by the removal of an invasive species that out-competes native vegetation and alters the natural desert ecosystem functions and values by limiting the habitats that supports native flora and fauna populations (Shaforth et. al, 2009).

[14] See the discussion of the California Water Code, Section 1200 "Water Rights" under Compliance with LORS and State Policies, below.

Tamarisk (salt cedar) is native to southwestern Asia and was introduced to the United States in the early 1800's for wind breaks. In the western United States, tamarisk is a highly invasive weed that has taken hold in semi-arid and arid watersheds in recent decades (de Gouvenain, 1996). Tamarisk can consume up to 250 gallons of ground water per day per mature tree (Department of Ecology, 2009).

A Tamarisk Removal Program has the potential to conserve a substantial amount of groundwater consumption within the Lower Colorado River area by removing a high water demand habitat that also monopolizes resources and negatively impacts native habitats in the area. A summary of water consumption estimates based on two scenarios is provided in **Soil & Water Resources Tables-17** and **-18**.

Soil & Water Resources Table 17
Water savings assuming mature trees

VARIABLES		CALCULATIONS	
5	acres	Trees/Acre	217.8
250	gallons/tree/day	Trees Removed	1,089
200	sf/tree	Gallons/Day	272,250
43560	sf/acre	Gallons/Year	99,371,250
365	days/year		
325,851	gal/acre-foot	Acre-feet/Year Savings	305

Soil & Water Resources Table 18
Water savings assuming a mixture of mature and immature trees

VARIABLES		CALCULATIONS	
7	acres	Trees/Acre	435.6
100	gallons/tree/day	Trees Removed	3,049
100	sf/tree	Gallons/Day	304,920
43560	sf/acre	Gallons/Year	111,295,800
365	days/year		
325,851	gal/acre-foot	Acre-feet/Year Savings	342

According to the Lower Colorado River Multi-Species Conservation Program – Final Biological Assessment (LCR 2004), the extent of land cover associated with salt cedar (Tamarisk) is over 26,000 acres in the area surrounding the Palo Verde Valley (referred to as Reach 4 of the Lower Colorado River). A Tamarisk Removal Program would only be required to remove 5 acres of mature trees or 7 acres of a mixture of mature/immature trees to achieve a water savings of over 300 afy. Correspondingly, there is more than sufficient salt cedar land cover type for the project owner to implement a water conservation mitigation program using tamarisk removal in the lower Colorado River area.

Program implementation, maintenance, and monitoring could be funded through an Endowment Fund established by the project owner. The fund could be held and managed by the BLM and/or Resource Conservation District based on resources and mechanisms available. The BLM and Resource Conservation District would use the fund to facilitate and manage implementation of the program.

With respect to the quantity of water that must be replaced, staff understands that the quantity of water identified in Condition of Certification **SOIL&WATER-14** is based on a simplified methodology for calculating contribution of water from the Colorado River from the project's proposed groundwater extraction and determining the appropriate mitigation. If the project owner chooses to refine the estimate of the quantity of water contributed by the Colorado River from project groundwater extraction they should be required to implement Condition of Certification **SOIL&WATER-17**. The results of this analysis can be used to refine the estimate of the volume of water that must be replaced in accordance with Condition of Certification **SOIL&WATER-14**.

<u>Mitigation</u>

There is a potential that groundwater production at the project site may induce additional inflow from the Colorado River which would be a significant impact. Implementation of the Condition of Certification **SOIL&WATER-14** is anticipated to reduce the potential for impacts to the Colorado River below the level of significance. The project owner could choose to conduct the analysis described in Condition of Certification **SOIL&WATER-17** to refine the quantity of water contributed by the Colorado River from project groundwater extraction. Because the modified PSEGS project would use a reduced amount of water during both construction and operation activities with the same proposed groundwater supply system as the approved PSPP project, staff believes that Conditions of Certification **SOIL&WATER-14** and **SOIL&WATER-17** as approved in the Commission Decision would also apply to the modified PSEGS project.

GROUNDWATER LEVELS

Because the modified PSEGS project would use a reduced amount of water during both construction and operation activities with the same proposed groundwater supply system as the approved PSPP project, staff believes that this does not constitute a project change from the approved project. Therefore, the following groundwater levels discussion has been included in this analysis from the Revised Staff Assessment for PSPP (CEC 2010c §C.9). Some minor edits were made for clarification.

The project has the potential to lower groundwater levels as a result of water production during both construction and operations. The lowering of groundwater levels could create a significant impact if the lowering of the groundwater levels: 1) impacts existing water wells in the basin; 2) lower the water table in areas where deep-rooted phreatophytes are prevalent[15], and/or 3) induce permanent ground subsidence.

[15] See the **BIOLOGICAL RESOURCES** section of this FSA for impacts related to biological resources.

Drawdown imposed by a well on another nearby pumping well can have adverse effects on the performance of that well and is referred to as interference drawdown or well interference. Specific potential adverse effects evaluated in this study include the following:

1. Interference drawdown can result in the water level of an aquifer being drawn down below the screen of the well (*i.e.*, the well goes dry);

2. Interference drawdown can result in the water level of an aquifer being drawn down to a point where the affected well's capacity to pump water is decreased and the well can no longer produce the amount of water that is needed for a particular use, or the well is at risk of becoming damaged and unusable over time due to exposure of the well's screen above the water table and resulting corrosion;

3. Interference drawdown can result in the water level in the affected well being drawn down to near the intake of the well's pump, requiring lowering of the pump intake in order for the well to remain operational; and/or

4. Interference drawdown can cause a decrease in groundwater level in the affected well such that the well and pump can continue to operate and produce adequate amounts of water, but pumping must occur at either greater frequency or duration, and/or water must be lifted to a greater height, resulting in greater operational and maintenance costs.

   The extent and type of well interference experienced by an affected well is dependent on hydrogeologic conditions in the aquifer as well as the characteristics of the affected well. These include the following:

   - The amount of interference drawdown that is applied [which varies with the distance of the impacted well from the project well(s)];
   - The depth and screened interval of the affected well;
   - The thickness of saturated sediments penetrated by the affected well;
   - Local variations in the transmissivity of the saturated sediments in which the affected well is completed, if any;
   - The condition and efficiency of the affected well;
   - The affected well's pump specifications, including its rating curve, the depth at which the pump intake is set, and the resulting pumping water level in the well during operation; and
   - The minimum required water production rate of the well.

Phreatophyte trees such as Mesquite, Ironwood or Palo Verde have deep root systems that can extend tens of feet below the ground surface to the underlying water table. In addition, wet playas can harbor halophyte plant communities that depend on a shallow water table for their moisture. Lowering of the water table below the root depth of these plants could result in stress or death.

Ground subsidence can occur as a result of water level decline in aquifer systems. When the fluid pressure in an aquifer is reduced as a result of changes in the groundwater level, a shift in the balance of support for the overlying materials causes the “skeleton” of the aquifer system to deform slightly. Reversible deformation occurs in all aquifer systems as a result of the cyclical rise and fall of groundwater levels associated with short and longer term climatic cycles. Permanent ground subsidence can occur when pore water pressures in the aquifer fall below their lowest historical point, and the particles in the aquifer skeleton are permanently rearranged and compressed. Soils particularly susceptible to such consolidation and subsidence include compressible clays in a confined aquifer system. This type of deformation is most prevalent when confined alluvial aquifer systems are overdrafted.

Construction and Operation

Compared to the approved PSPP project, the modified PSEGS project would reduce water use both during construction (from 5,750 af to 1,130 af) and during operation (from 300 afy to 201 afy). As a result, the overall water use of PSEGS could be roughly half that of PSPP (7,160 af compared to 14,750 af). Because this reduction in groundwater use would reduce the potential effects on groundwater levels, the conditions of certification in the Commission Decision (CEC 2010f), which fully mitigated the PSPP groundwater use, would also fully mitigate PSEGS groundwater use. The project owner has not revised the groundwater modeling for the modified PSEGS project’s water use, therefore staff included the following PSPP groundwater analysis as an overly conservative scenario of groundwater level impacts.

The maximum predicted water table drawdown associated with the PSPP project is approximately 26 to 46 feet in the area of the pumping wells occurring at the end of construction (see **Soil & Water Resources Table 19**), and the area where drawdown exceeds 1 foot is limited to within approximately 1 to 3 miles of the project ROW. **Soil & Water Resources Figures 13** and **14** present groundwater level decline contours from the approved PSPP production wells at the end of construction and end of operations, respectively.

Soil & Water Resources Table 19
Results of Numerical Modeling for PSPP Project[1]

Model Runs	Zone 1[2]		Zone 2[2]		Zone 3[2]		Year	Maximum drawdown (feet)				Change in storage (acre-feet)

Notes

1 - Refer to Soil & Water Resources Table 21(bottom row) for the water use schedule that was used to run these models.
2 - Figure DR-S&W-207-3 shows the areal distribution of transmissivities used in the model
3 - Used to determine relative sensitivity of the aquifer parameters and a conservative radius of influence for Zone 1 delineation using upper bound transmissivity for a single pumping well
4 - Used to determine relative sensitivity of the aquifer parameters and a conservative radius of influence for Zone 1 delineation using mid-value transmissivity for a single pumping well
5 -Used to determine relative sensitivity of the aquifer parameters and a conservative radius of influence for Zone 1 delineation using lower bound transmissivity for a single pumping well

The nearest potential wetland or halophyte communities would be near Palen Dry Lake. Groundwater dependent vegetation lies approximately 3-6 miles from the project site. A preliminary estimate of the groundwater level decline indicates approximately 0.2 to 0.6 feet of decline at the end of operations (33 years). The **BIOLOGICAL RESOURCES** section of this FSA describes potential impacts to vegetation that may be dependent on shallow groundwater table conditions.

Given the current understanding of the hydrogeology of the Quaternary Alluvium, the Bouse Formation and the Fanglomerate, as well as the current understanding concerning existing wells that may be affected by project-induced drawdown, it is unlikely that groundwater pumping for the project would cause any nearby wells to go dry or be severely impaired or rendered unusable by declining groundwater levels. However, groundwater levels would decline and could affect nearby wells. While preliminary studies and calculations have been made to assess the potential for impact, the quantification of the impact is considered an estimate and cannot be accurately quantified until actual long-term groundwater production occurs. Condition of Certification **SOIL&WATER-2** through **SOIL&WATER-5** are expected to minimize impacts to groundwater levels below the level of significance.

The potential for subsidence from groundwater level declines is believed to be remote. However, it is recommended that a monitoring and mitigation program be implemented to assess long term changes that may occur as a result of groundwater pumping in the area. The project owner should also be required to implement **SOIL&WATER-16** to monitor and mitigate any potential impacts associated with ground subsidence associated with groundwater pumping.

Mitigation

Groundwater levels near the project's water supply wells would decline during the project pumping. Local decline of groundwater levels within the cone of depression could affect nearby wells. While preliminary studies and calculations have been made to assess the potential for impact, the quantification of the impact is considered an estimate and cannot be accurately quantified until actual long-term groundwater production occurs. Conditions of Certification **SOIL&WATER-2** through **SOIL&WATER-5** are expected to minimize impacts to groundwater levels below the level of significance. Staff has required these types of conditions in previous cases and finds that they are effective in addressing any impacts to nearby wells that may occur as a result of project pumping.

The project must implement Condition of Certification **SOIL&WATER-16** that requires a Subsidence Monitoring and Action Plan to assess and mitigate potential effects of non-elastic subsidence associated with groundwater extraction in the vicinity of the proposed production wells.

Because the modified PSEGS project would use a reduced amount of water during both construction and operation activities with the same proposed groundwater supply system as the approved PSPP project, staff believes that Conditions of Certification **SOIL&WATER-2** through **SOIL&WATER-5** and **SOIL&WATER-16** as approved in the Commission Decision would also apply to the modified PSEGS project.

GROUNDWATER QUALITY

Because the modified PSEGS project would use a reduced amount of water during both construction and operation activities with the same proposed groundwater supply system as the approved PSPP project, staff believes that this does not constitute a project change from the approved project. Additionally, the modified PSEGS project would use a reduced number of evaporation ponds using the same type proposed for the approved PSPP project. Therefore, the following groundwater quality discussion has been included in this analysis from the Revised Staff Assessment for PSPP (CEC 2010c §C.9). Some minor edits were made for clarification and additional information added to compare the approved PSPP project and modified PSEGS project.

Construction

There is a potential that significant groundwater quality impacts could occur during construction if contaminated or hazardous materials used during construction were to be released and migrate to the groundwater table. Given the distance to the groundwater table (180 feet bgs) and the proposed implementation of a hazardous material management plan during construction[16], potential impacts to groundwater quality are expected to be maintained below the level of significance.

There is a potential that project extraction of groundwater may induce vertical flow of high saline groundwater from beneath Palen Dry Lake to lower aquifers (being used for water production) located beneath the site. At the present time, no significant differential in groundwater quality has been identified beneath the project. AECOM conducted a hypothetical analysis (AECOM 2010a) where high saline groundwater was present beneath Palen Dry Lake and that the production wells planned for the project would induce a gradient towards the production well. Using variable values of hydraulic conductivity based on-site specific data, the results indicate that it will take between about 43 years to 4,424 years for groundwater to flow from beneath Palen Dry Lake to the project wells. Given that there are probably low permeability sediments present beneath Palen Dry Lake and the analysis did not take into consideration retardation, dispersion or dilution and/or interference from other producers, it is unlikely that significant vertical migration of poor quality water would migrate and degrade higher quality portions of the aquifer. However, due to the uncertainty associated with the amount of information available concerning shallow groundwater quality and vertical migration, Conditions of Certification **SOIL&WATER-2** through **SOIL&WATER-4**, and **SOIL&WATER-18** are expected to minimize impacts to groundwater quality below the level of significance.

Because the modified PSEGS project would use a reduced amount of water during construction activities with the same proposed groundwater supply system as the approved PSPP project, staff believes that Conditions of Certification **SOIL&WATER-2** through **SOIL&WATER-4** and **SOIL&WATER-18** as approved in the Commission Decision would also apply to the modified PSEGS project.

[16] As required by Condition of Certification **HAZ-3** (see the **HAZARDOUS MATERIALS MANAGEMENT** section of this FSA).

Operation

Groundwater Pumping

There is a potential that project extraction of groundwater may induce vertical flow of high saline groundwater from beneath Palen Dry Lake to lower aquifers (being used for water production) located beneath the site. At the present time, no significant differential in groundwater quality has been identified beneath the project. Given the possibility that there is shallow groundwater below the lake and the lake serves as a point of discharge of groundwater, it is reasonable to presume that there could be high concentrations of TDS below the lake (AECOM 2010a). A calculation was conducted by AECOM using estimates of hydraulic conductivity, effective porosity, gradient and distance and where high saline groundwater was present beneath Palen Dry Lake and that the production wells planned for the project would induce a gradient towards the production well. Using the estimated values of the variables based on-site specific data, the hand calculated results indicate that it will take between about 43 years to 4,424 years for groundwater to flow from beneath Palen Dry Lake to the project wells (AECOM 2010a). Given that there are probably low permeability sediments present beneath Palen Dry Lake and the analysis did not take into consideration retardation, dispersion or dilution and/or interference from other producers, it is unlikely that significant vertical migration of poor quality water would migrate and degrade higher quality portions of the aquifer. However, due to the uncertainty associated with the amount of information available concerning shallow groundwater quality and vertical migration, Conditions of Certification **SOIL&WATER-2** through **SOIL&WATER-4**, and **SOIL&WATER-18** are expected to minimize impacts to groundwater quality below the level of significance.

Because the modified PSEGS project would use a reduced amount of water during operation activities with the same proposed groundwater supply system as the approved PSPP project, staff believes that Conditions of Certification **SOIL&WATER-2** through **SOIL&WATER-4** and **SOIL&WATER-18** as approved in the Commission Decision would also apply to the modified PSEGS project.

Evaporation Ponds

The approved PSPP project would have had four double-lined evaporation ponds. Each pond would have had an evaporative surface area of 4 acres resulting in a total of 8 acres of evaporation ponds for each unit or a total of 16 acres of ponds for the entire approved PSPP project. The modified PSEGS project would construct two double-lined evaporation ponds, each with 2 acres of evaporative surface area resulting in a total of four acres of ponds for the entire modified project.

The ponds would be designed and permitted as Class II Surface Impoundments in accordance with CRBRWQCB requirements, as well as the requirements of the California's Department of Resources Recycling and Recovery (CalRecycle). Multiple ponds are planned to allow plant operations to continue in the event that a pond needs to be taken out of service for some reason, *e.g.,* needed maintenance. Each pond would have enough surface area so the evaporation rate exceeds the input rate at maximum design conditions and annual average conditions.

For the approved PSPP project, the average pond depth is 7 feet and residual precipitated solids would have been removed every 4 years to maintain a solids depth no greater than approximately 2 feet for operational and safety purposes. The ponds would have maintained a minimum of 2 feet of freeboard to minimize the potential for overtopping due to a 100-year recurrence interval rainfall event. A total estimated amount of evaporites accumulated is 6,400 tons over 30 years.

For the modified PSEGS project, ponds 6 feet deep would be constructed without the need for periodic removal of solids over the 30 year life of the facility. Ponds are designed for an ultimate salt depth of 3.2 feet and a maximum water depth of 1.0 feet. A 100-yr, 24-hour storm event is estimated by NOAA to yield 0.4 feet (4.22 inches) of rain. A minimum freeboard of 1.0 foot would be maintained during the life of the ponds (Palen 2013a Appendix 2-B).

The pond liner system would consist of a 60 millimeter high density polyethylene (HDPE) primary liner and a secondary 40 millimeter HDPE liner. Between the liners is a synthetic drainage geonet and collection piping that is used as part of the leachate detection system (LDS), which would be directed back to the pond. There would be a hard surface protective layer on top of the 60 millimeter HDPE which would consist of a hard surface such as roller-compacted concrete. The hard surface provides protection against accidental damage to the HDPE from falling objects, varying climatic conditions, and worker activities during cleanout and maintenance. Monitoring of the evaporation ponds would be required to detect the presence of liquid and/or constituents of concern. Although the modified project would create less process wastewater per year compared to the approved project, the constituents of concern would occur in higher concentrations.[17] Due to the aforementioned construction and operational procedures of the surface impoundments (see Condition of Certification **SOIL&WATER-6** and its Appendices B, C, and D) along with Condition of Certification **SOIL&WATER-18**, groundwater quality is not anticipated to be affected as a result of disposal of this waste stream and impacts to groundwater quality would be below the level of significance.

Land Treatment Unit

The approved project proposed use of a Land Treatment Unit (LTU) to treat contaminated soils as a result of accidental spills of heat transfer fluid (HTF) that occur during the course of daily operational or maintenance activities. The Commission Decision required compliance with Condition of Certification **SOIL&WATER-6** (with requirements specified in Appendices B, C, and D) to ensure that the operation of the LTU is in accordance with regulatory requirements and would minimize potential impacts to surface and groundwater quality. In addition, Condition of Certification **SOIL&WATER-18** required the approved project to monitor existing groundwater quality to monitor compliance with the requirements set forth in **SOIL&WATER-6**.

[17] A thermal evaporator system would treat process wastewater, and concentrated waste brine would be transported to the evaporation ponds. See the Process Wastewater discussion under “Proposed Modified Project” above.

The modified PSEGS project does not require use of an LTU for solar tower technology. Although this results in a reduced impact compared to the approved project, the waste discharge requirements specified in Appendices B, C, and D have been revised to reflect the modified project. Staff believes that the revisions in Appendices B, C, and D would not affect the language of existing Conditions of Certification **SOIL&WATER-6** or **SOIL&WATER-18**.

Septic Field

The use and application of septic fields is an established practice as a method of wastewater treatment. The septic system would have no affect on the surface water in or around the project site. The septic system would be installed approximately 5-6 feet deep. In addition, the Riverside County Department of Environmental Health has a Technical Guidance manual for Onsite Wastewater Treatment Systems and this requires a setback of 100 feet between this type of system and the nearest groundwater well.

Individual septic systems and leach fields are planned for each of the two power blocks and the project's administrative, warehouse, and control room and facilities. The proposed septic systems and leach fields for the various facilities are hydraulically down-gradient from the nearest offsite well. Therefore, operation of the septic systems and leach fields from these areas are not expected to impact groundwater quality at the nearest offsite wells.

The septic system and leach fields for the project would be constructed in accordance with the requirements of Riverside County and Condition of Certification **SOIL&WATER-7**:

1. Ordinance 650.5 (amends Ordinance 650 that regulates the discharge of sewage in unincorporated areas of the County of Riverside and incorporates by reference Ordinance 725);

2. Title 15 Section 15.24.010 (the Uniform Plumbing Code) Appendix K for Private Sewage Disposal – General and Disposal Fields; and

3. Title 8 Section 8.124.030 (Approval and Construction Permit for Sewage Discharge) and Section 8.124.050 (Operation Permit for Sewage Disposal).

Because the modified PSEGS project would employ a comparable number of fulltime workers during operation as the approved PSPP project,[18] staff believes that Condition of Certification **SOIL&WATER-7** as approved in the Commission Decision would also apply to the modified PSEGS project.

[18] The approved PSPP project estimated 134 full time employees would be needed with both units operating. The modified PSEGS project estimates to employ up to 100 full time employees.

Mitigation

Groundwater quality in the vicinity of the project site could be impacted as a result of the operation of the surface evaporation impoundments and septic fields. Preliminary studies and calculations have been made to assess the potential for impact. These studies suggest that there is a low potential to impact groundwater quality in the vicinity of the project site. Due to the uncertainty associated with the potential to impact groundwater quality and the regulatory requirements for operation of the surface evaporation impoundments and septic systems, staff recommends implementation of specific monitoring and mitigation requirements.

The Commission Decision required Conditions of Certification **SOIL&WATER-6**, **SOIL&WATER-7** and **SOIL&WATER-18** to minimize impacts below a level of significance. Staff believes these conditions as approved in the Commission Decision would also apply to the modified PSEGS project.

SURFACE WATER HYDROLOGY

The modified project proposes substantial changes to the site hydrology compared to the approved project. The modified project removes the three major drainage channels from the approved project that was designed to route the water through and around the entire field of solar troughs. Instead, the heliostat technology of the modified project would allow most flows to maintain existing, pre-project natural drainage patterns through the solar fields.[19] Although these differences would inherently reduce the impacts of water diversion compared to the approved project, these changes in hydrology could potentially create issues that were not analyzed during assessment of the approved project. Therefore, the following surface water hydrology discussion is entirely independent of the analysis found in the Revised Staff Assessment for PSPP.

Flooding

Flooding is usually defined as the inundation of dry land adjacent to a channel when excess flow exceeds its banks. Because ephemeral streams like those at the site do not have permanent flow, their banks are formed in response to rainfall events which are infrequent and vary in intensity. The extreme changes in flow conditions causes flooding, erosion, and sedimentation that can drastically alter the channel's shape and alignment. Consequently, desert washes can be transient and may vary in course from one storm event to another (resulting in heavy braiding of shallow channels). For purposes of this analysis, impacts of flooding consider the natural behavior of ephemeral streams.

[19] Because the modified project does not propose the major drainage channels, staff recommends deletion of the following Conditions of Certification pertaining to these large channels: SOIL&WATER-8 through SOIL&WATER-12. (See "Proposed Conditions of Certification" below.)

Onsite Area Flooding

Proposed construction of the PSEGS project would alter existing onsite drainage patterns which could potentially cause or increase onsite flooding. For the majority of the project site, existing drainage patterns would generally remain the same. However, changes to a number of areas such as grading, adding impervious surfaces, diverting flows, and impeding flows can increase the amount of storm water runoff volume and rate. An analysis of each impact and the project owner's proposal to address impacts follows below.

Grading and Increase of Impervious Area

Heavy to medium grading would be performed within each solar plant's power block area and the common area complex. Grading would also be needed to create a system of roadways for access to each facility and maintenance of the heliostats, although grading in the solar fields would match natural contours and promote sheet flow where possible. Estimated amount of total grading (both temporary and permanent) would be about 413 acres, as shown in **Soil & Water Resources Table 4**. After project completion, the temporary parking and construction laydown areas would be restored to pre-project grade and stabilized to prevent erosion and promote natural revegetation.[20]

While most of the permanently graded area would remain "dirt" surface, the addition of concrete foundations and asphalt paving would create approximately 25 acres of impervious surface. Because water is not able to infiltrate into impervious surfaces, storm water runoff quickly concentrates and flows downstream, increasing both the volume and velocity of accumulated water. In addition, the heliostat assemblies would essentially function as thousands of rooftops and create approximately 799 acres of impervious surfaces, covering about 21 percent of the project site (see **Soil & Water Resources Table 4**). However, because the heliostats would be installed such that surface runoff flows to the pervious dirt areas of the solar field, impacts are considerably less severe than a contiguous stretch of impervious area.

The project owner submitted Preconstruction Hydrology Calculations (Palen 2013e Attachment G) showing that a 100-year, 24-hour storm event[21] would likely result in flood flows approximately one-to two-feet deep, with spot locations of three to four feet deep (see **Soil & Water Resources Figure 12**). Staff acknowledges the project owner has completed a thorough hydrologic analysis, but notes that predicted flow depths and velocities on undeveloped alluvial fans have potential uncertainty. The consequences of flash flood damage or modified sedimentation and erosion rates may be significant. Staff proposes Condition of Certification **SOIL&WATER-20** (Storm Water Damage Monitoring and Response Plan) to reduce potential impacts caused by large storm event in four ways:

[20] As required by Condition of Certification **BIO-8**, Item 22 (see the **BIOLOGICAL RESOURCES** section of this FSA).

[21] A design storm event is a hypothetical storm event, of a given frequency interval and duration, used to estimate how often storms of a given magnitude will occur, based on historical rainfall information. A 100-year, 24-hour design storm event corresponds to a major storm (the probability of occurrence in any given year is one in 100, or a one percent chance) and is used to represent flows with the potential to cause property damage and other impacts.

1. Establish specifications for heliostat installation based on-site specific studies and reports (e.g. Pylon Insertion Depth and Heliostat Stability Report). This ensures that heliostats are designed to withstand storm water scour of a 100-year storm event;

2. Establish an ongoing maintenance plan to ensure all storm water management measures are functioning properly, though periodic inspection before the first seasonal storms and after each storm event throughout the year;

3. Establish and implement a response plan to clean up damage and prevent release of sediment or pollutants after every occurrence of damage from a storm event or other cause; and

4. Develop and implement a process to monitor incidents and propose modifications and/or improvements to address ongoing issues.

Furthermore, as the modified project plans evolve from the conceptual and preliminary phases, any changes affecting hydrology or hydraulics would require an updated comprehensive analysis for purposes of **SOIL&WATER-20**. For example: the use of certain commercial dust suppressants applied onto dirt roads that would increase the total impervious area of the site.

In addition, standing water onsite might have impacts to biological resources given the scarcity of water in the desert. For example, increasing the amount of standing water due to grading and construction has the potential to attract nuisance predators such as ravens to the site. (See the **BIOLOGICAL RESOURCES** section of this FSA for further discussion on the potential impacts of standing water to biological resources and possible mitigation required.)

Tropical storms in this region are mostly unpredictable, and flash floods can result in an enormous amount of water in a very short time. Because people tend to underestimate the dangers of a flash flood, they may attempt to drive or walk through the swift flows to cross it. However, as little as two feet of water is enough to carry away most passenger vehicles, and swiftly moving water six inches deep can cause a person to lose balance.[22] Although the administration building and both power blocks would be located outside of the large desert washes, the paved main access road connecting the power blocks and several other internal unpaved roads would be placed within washes that are expected to flood during heavy storms. To avoid injury or death during a large flood event, the project would require a Construction Flood Safety Plan and Operations Flood Safety Plan to protect personnel at the project site (see **WORKER SAFETY-1** and **-2** in the **WORKER SAFETY AND FIRE PROTECTION** section of this FSA). These Plans would provide safety procedures for onsite workers during a very large flood event (100-year flooding or larger).

[22] NOAA, March 2005, Publication# PA 200467

Diversion Channels

In three areas (Solar Plant 1, Solar Plant 2, and the administration building), permanent diversion channels would be constructed to redirect storm runoff around these structures and prevent damage from flooding that occurs naturally due to existing topography. Although the administration building and solar blocks would be generally located outside these flooded areas (see **Soil & Water Resources Figure 15**), desert washes can be transient and may vary in course from one storm event to another. The diversion channels around the administration building and each solar block would protect these structures from natural ephemeral flooding. Because of the general flow-through design of the solar fields, the diversion channels would not redirect runoff flows in a way that would adversely flood other areas either onsite or offsite. Also, **SOIL&WATER-20** (Storm Water Damage Monitoring and Response Plan) would require maintenance and monitoring of diversion channels during operations for added protection against storm damage.

In addition to the permanent diversion channels, the draft DESCP shows temporary diversion channels that would redirect flows around construction laydown and temporary parking areas during the construction activities of the modified project (Palen 2013g). Their general location outside the existing desert washes (see **Soil & Water Resources Figure 15**) reduces the potential for these temporary diversion features to cause significant onsite flooding. However, staff believes that the possibility of unplanned rerouting of natural drainage patterns could cause significant onsite flooding, particularly during construction activities when soil is most exposed and BMPs may not be fully functional. Also, some construction practices that typically occur at other construction sites can have unintended impacts in a desert setting with ephemeral washes. For example, a temporary dirt access road used to transport heavy equipment across the site can block the path of a large desert wash (braiding of shallow channels that could be a mile wide and very difficult to identify). Because tropical storms in this regional are mostly unpredictable and can have short bursts of very intense rainfall, a seemingly minor rerouting of storm water flows can result in significant flooding damage. Construction period flooding can result in damages to onsite facilities, interference with the construction schedule, and potential exposure of workers to flood conditions. Staff added language to Item C of Condition of Certification **SOIL&WATER-1** to minimize these impacts.

Offsite Area Flooding

Grading and Increase of Impervious Area

Numerous ephemeral drainages flow through the proposed PSEGS site, originating from the southwest and discharging to the northeast toward the Palen Dry Lake bed. Due to the episodic rainfall of the region and transient nature of the drainages, offsite flows can easily exceed these shallow channels and result in flooding. Modeling of the site in its present undeveloped state results in offsite flows to areas downstream as shown in **Soil & Water Resources Figure 15**. Proposed grading and construction of PSEGS would increase the amount of impervious area onsite. This would increase the amount of storm water peak discharge leaving the site and could exacerbate the naturally occurring floods downstream of the site.

The project owner submitted a Developed Conditions Drainage Assessment (Palen 2013a Appendix A) that modeled post-construction onsite peak flows, runoff volumes, maximum velocities, and maximum depths of potential floods. The analysis represented post-construction site conditions by incorporating the following proposed elements: impervious surfaces (heliostats, buildings, asphalt roadways and parking lots), and graded dirt roads. **Soil & Water Resources Table 20** presents the estimated peak flows leaving the site calculated from cross-sections located along the northeast border (as shown in **Soil & Water Resources Figure 15**). Because cross sections are different widths, the table calculates the average flow per foot across each cross section.

Soil & Water Resources Table 20
Estimated Peak Flows Discharging from PSEGS Site

Floodplain Cross Section		100-year Storm Event					
		Pre-construction		Post-construction		Flow Increase	
No.	Approx. Width	Peak Flow	Flow per foot	Peak Flow	Flow per foot	cfs	Flow per foot
CS-1	6200 ft	7053.8 cfs	1.14	7160.3 cfs	1.15	106.4	0.02
CS-2	1400 ft	299.0 cfs	0.21	520.8 cfs	1.74	221.8	0.16
CS-3	6400 ft	5132.1 cfs	0.80	5342.9 cfs	0.83	210.8	0.03
CS-4	9000 ft	1005.5 cfs	0.11	1059.8 cfs	0.12	54.3	0.01

Source: Palen 2013a Appendix A
cfs = cubic feet per second

Because the peak discharge of the 100-year, 24-hour storm event leaving the site during post construction conditions would be very close to discharge of preconstruction conditions, the impacts of offsite downstream would be reduced. Staff acknowledges the project owner has completed a thorough hydrologic analysis, but notes that predicted flow depths and velocities on undeveloped alluvial fans have potential uncertainty. The consequences of flash flood damage or modified sedimentation and erosion rates may be significant. Staff proposes Condition of Certification **SOIL&WATER-20** requiring a Storm Water Damage Monitoring and Response Plan to reduce these potential impacts.

Flood Hazards

Flood hazards include direct flooding due to overtopping of nearby rivers or streams resulting from severe rainstorms, or secondary flooding due to seismic activity creating tsunamis (tidal waves) or seiches (waves in inland bodies of water).

To identify the different types of flood risks for a given location, flood hazard maps were developed by the Federal Emergency Management Agency (FEMA) to identify areas prone to flooding. Comparing the PSEGS site location to these maps, staff found that:

- PSEGS is not located within the 100-year floodplain as defined by FEMA; and
- PSEGS site is located roughly 150 miles inland with no dams in the region. In addition, no levees or inland bodies of water are located in the area.

The proposed project would not impede or significantly redirect flood flows of the FEMA designated 100-year floodplain. In addition, the project would not be affected by dam failure, tsunami, or seiche. PSEGS would not have significant impacts pertaining to these identified flood hazard areas. (For discussion on additional potential hazards that could be caused by soil failure such as mudflow, landslide and liquefaction, see the **GEOLOGY AND PALEONTOLOGY** section of this FSA.)

Mitigation

The Implementation of Conditions of Certification **SOIL&WATER-1**and **SOIL&WATER-20** are anticipated to minimize impacts related to flood hazards and erosion associated with construction and operation of the modified project to below the level of significance. They also provide the basic information to assist the Energy Commission Compliance Project Manager (CPM) to adequately review and assess the appropriateness of the proposed design within the context of the site specific conditions.

SURFACE WATER QUALITY

Project storm water runoff may encounter soil or chemicals deleterious to aquatic and terrestrial plant and wildlife. The project owner proposes to implement BMPs for managing potentially harmful storm water and protecting water quality. Potentially significant water quality impacts could occur during operations if contaminated or hazardous materials used during operations were to contact storm water. Contact runoff[23] could concentrate various pollutants that would then discharge to an offsite water resource. The modified project would alter natural storm water drainages around the common area and around each solar power block. BMPs would be implemented to reduce potentially significant impacts related to concentrated drainage and ensuing soil erosion and sediment transport offsite. The following discusses the potential impacts and the proposed Conditions of Certification below.

Construction

Potential threats to surface water quality related to construction includes potential increases in sediment loads to adjacent streams and washes, and accidental spills of hydrocarbon fuels and greases associated with construction equipment. The SWRCB and CRBRWQCB have determined that standardized storm water and soil erosion BMPs are the most effective, practical means to protect surface waters by preventing or reducing pollution from nonpoint sources. Staff agrees that carefully chosen BMPs for both construction and operation activities would effectively prevent or reduce sediment discharge into water resources. Potential increased sediment loads would be mitigated through development and implementation of a Drainage Erosion and Sedimentation Control Plan (DESCP) which is required as part of Condition of Certification **SOIL&WATER-1.**

[23] Contact runoff refers to storm water in contact with exposed polluted or hazardous materials and/or surfaces can potentially result in contaminated runoff (containing trace oil, chemicals, metals, toxic substances, or other materials).

To prevent contact runoff from discharging offsite during construction activities, the project owner has identified a combination of standard BMPs within the DESCP for pollution control measures to be implemented during construction. The BMPs would limit or reduce potential pollutants at their source before they come into contact with storm water. These BMPs also involve daily activities of the construction site, are under the control of the construction contractor, and are additional “good housekeeping practices,” which involve maintaining a clean and orderly construction site.

Accidental spills of hydrocarbon fuels and greases associated with construction equipment would also be mitigated by the development and implementation of Condition of Certification **HAZ-3** in the **HAZARDOUS MATERIALS MANAGEMENT** section of this FSA, which includes development of a Safety Management Plan for the delivery and handling of liquid and gaseous hazardous materials. In summary, implementation of BMPs as defined in Condition of Certification **SOIL&WATER-1** and Condition of Certification **HAZ-3** would reduce potential water quality impacts to insignificant.

Operation

Potential threats to surface water quality related to operations includes: potential increases in sediment loads to adjacent washes; accidental spills of hydrocarbon fuels and greases associated with operations equipment; and accidental releases from the surface impoundments that include process wastewater.

To prevent the discharge of untreated industrial wastewater or untreated sanitary wastewater from entering nearby water resources, each PSEGS Solar Plant would keep the potentially polluted waste water (contact runoff, general facility drainage, process wastewater, and sanitary waste) completely separated from non-contact storm water runoff. Sanitary waste would remain contained within the septic system. Industrial wastewater would remain within the power block, processed through the thermal evaporator system, then disposed into the evaporation ponds. Hazardous liquids would be handled to prevent spills and accidental release. Non-contact storm water would be directed away from the power blocks and allowed to flow offsite toward the northeast. All BMPs and conditions of certification would strive to prevent any chemical or hazardous pollutants from mixing with the "clean" storm water. With the implementation of these measures, impacts from sanitary or industrial wastewater would be avoided or reduced to less than significant during operation of the proposed project.

A DESCP would be required (see Condition of Certification **SOIL&WATER-1**) prior to onsite operations and would reduce the potential for increased sediment loads to less than significant. Potential spills would be managed through hazardous materials management in Condition of Certification **HAZ-2** (see the **HAZARDOUS MATERIALS MANAGEMENT** section of this FSA), which includes development of a Spill Prevention, Control and Countermeasure (SPCC) Plan. The SPCC Plan sets forth spill prevention methods as well as actions to be taken in the event of an accidental spill or release of hazardous materials.

The operation of the surface impoundments would include one foot of freeboard to minimize the potential for overtopping during a 100-year precipitation event. In addition, the surface impoundments would operate under the waste discharge requirements that include operational and leak detection monitoring as stipulated in **SOIL&WATER-6** and would reduce the potential for impacts to surface water quality to less than significant. Also, **SOIL&WATER-20** would reduce the potential of pollutants caused by storm damage from leaving the site.

Mitigation

No significant impacts are anticipated related to surface water quality. Implementation of Conditions of Certification **SOIL&WATER-1**, **-6,**and **-20** and **HAZ-2** and **-3** is anticipated to reduce impacts to surface water quality to below the level of significance associated with construction and operation of the modified project. Additional requirements for mitigation of potential surface water quality impacts would also be included as a part of the waste discharge requirements for the surface impoundment that would be included in Condition of Certification **SOIL&WATER-6.**

CUMULATIVE IMPACTS

A project may result in a significant adverse cumulative impact where its effects are cumulatively considerable. "Cumulatively considerable" means that the incremental effects of an individual project are significant when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects (California Code Regulations, Title 14, section 15130).

There is the potential for future development in the Chuckwalla Valley area and throughout the southern California desert region. Cumulative impacts can occur if implementation of the proposed modified project could combine with those of other local or regional projects. The locations of existing and reasonably foreseeable developments in the Chuckwalla Valley area are presented in the following sections.

Geographic Extent

As identified in the **EXECUTIVE SUMMARY** of this FSA, a number of projects within the region of the PSEGS have been approved, are under review, or in operation (see **Executive Summary Attachment A – Figure 1**). The geographic extent used as part of the cumulative impact assessment for soil and water resources includes the CVGB. The extent of the basin is described in the “Setting and Existing Conditions” discussion above, and shown in **Soil & Water Resources Figure 2**. Foreseeable projects that may impact the soil and water resources of the area were deemed to include only those projects located in the CVGB. **Soil & Water Resources Table 21** lists the foreseeable projects analyzed by staff for this FSA, which was updated from estimates calculated in the Revised Staff Assessment for PSPP (CEC 2010c §C.9). Changes to the list of foreseeable projects are based on:

- Delays in project schedules and estimates of delayed construction start dates
- Projects removed that are no longer forseeable
- Projects added that have become reasonably foreseeable

- Updated estimates of water use from published environmental documents

Construction and Operation

The construction of the modified project is expected to result in short term adverse impacts related to construction activities. It is expected that some of the cumulative projects listed in **Soil & Water Resources Table 21** which are not yet built may be under construction the same time as the modified project. In addition, it is expected that some of the future and foreseeable projects may be operational at the same time as the modified project. As a result, there may be substantial long term cumulative impacts during construction and operation of these projects related to soils and water resources.

These impacts may include: soil erosion, geomorphology, changes in the groundwater basin balance, groundwater levels, and groundwater quality, and changes in surface water hydrology and surface water quality.

Soil Erosion

Construction of the PSEGS would result in temporary changes at the project site which could incrementally increase local soil erosion and storm water runoff during construction. The PSEGS would be expected to contribute only a small amount to the possible short term cumulative impacts related to soil erosion because the project owner would be required to implement the Conditions of Certification defined in this analysis, which are expected to bring short term impacts below the level of significance.

Operation of the PSEGS would result in permanent changes at the project site. These changes could incrementally increase local soil erosion and storm water runoff. The PSEGS would not be expected to cumulatively contribute to these possible long-term operational cumulative impacts because potential project-related soil erosion and increased sedimentation resulting from storm water runoff are expected to be reduced to a level of insignificance through implementation of the Conditions of Certification specified below.

Geomorphology

There is a concern that implementation of all of the foreseeable projects could have a cumulative impact on the regionally significant geomorphic processes that transport sand downwind along the Chuckwalla Valley and to the Colorado River. Blocking or disrupting the sand transport corridors would impact various sites that provide habitat for biological resources such as MFTL. See the **BIOLOGICAL RESOURCES** section for further analysis of potential cumulative impacts related to geomorphic processes.

Groundwater Basin Balance

Staff evaluated whether the amount of groundwater used for both construction and operations would place the groundwater basin into overdraft and deplete the CVGB. For purposes of impact analysis, it is assumed that any withdrawals that exceed the average natural recharge and exceed a significant percentage of the total amount of groundwater in storage would be a significant impact. Appendix G of the CEQA Guidelines refers to “[substantial interference] with groundwater recharge such that there would be a net deficit in aquifer volume". The following discussion presents an analysis of the potential impacts to the groundwater basin balance and the potential for overdraft to occur.

A comparison was made between the average annual basin budget with the anticipated foreseeable projects' cumulative construction and operation water production requirements. **Soil & Water Resources Table 22** presents the anticipated projects water requirements (Years 2014-2046) along with the average annual basin budget. In 2010, the CVGB balance was positive by approximately 2,608 afy whereby inflow (approximately 13,719 afy) to the basin is slightly greater than estimated outflows (approximately 11,111 afy) to the basin.

Soil & Water Resources Table 22
Estimated Change to Chuckwalla Valley Groundwater Basin Budget
(Average Year Conditions)

Years	Annual Basin Budget Balance[1]	Cumulative Project Requirements (afy)[2]	Net Budget Balance (afy)	Cumulative Budget Balance (af)	Cumulative Positive/Deficit as a Percent of Total Recoverable Storage[3]
2014	2,608	1,189	1,419	1,419	0.009 percent
2015	2,608	1,491	1,117	2,536	0.017 percent
2016	2,608	999	1,609	4,145	0.028 percent
2017	2,608	8,543	-5,935	-1,790	-0.012 percent
2018	2,608	8,532	-5,924	-7,714	-0.051 percent
2019	2,608	8,532	-5,924	-13,638	-0.091 percent
2020	2,608	8,532	-5,924	-19,562	-0.130 percent
2021	2,608	3,154	-546	-20,108	-0.134 percent
2022	2,608	2,229	379	-19,729	-0.131 percent
2046	2,608	2,229	379	-10,633	-0.071 percent

Notes:
1 - See Soil & Water Resources Table 10
2 - See Soil & Water Resources Table 21
3 - Based on a total recoverable storage of 15,000,000 af.

It is anticipated that groundwater extraction of foreseeable projects listed in **Soil & Water Resources Table 21** would peak from 2017 to 2020 mainly due to water needed to fill reservoirs of the Eagle Mountain Pumped Storage project. During this period, groundwater extraction would exceed the basin balance by almost 6000 afy and place the basin into overdraft for five years.

The storage capacity of the CVGB is approximately 15,000,000 af. The amount of cumulative groundwater extraction anticipated for construction of the approved project and the future/foreseeable projects would amount to 0.03 percent of the total stored groundwater, which is not considered a significant impact. The projects are expected to reduce the amount of total stored groundwater by 0.07 percent by the end of the modified project's operational life, which is also not considered a significant impact.

Lastly, the I-10 corridor within the CVGB has been targeted for renewable energy projects that have not been identified or quantified as to quantity of water required for development. Given that perennial surface water sources are non-existent and the only available water source is groundwater, it is likely that these as yet unidentified projects could further develop the groundwater resources and exacerbate the cumulative overdraft conditions identified above. However, given the amount of total recoverable groundwater in storage (approximately 15,000,000 af), the impact would be insignificant.

In addition, the cumulative impact analysis conducted by the Genesis Solar Power Project located to the east of the Project suggested that during the course of operations for all foreseeable projects, the subsurface outflow from the CVGB would decline from approximately 400 afy to approximately 71 afy in 2043 (see Genesis 2010 Table 5-2). This could have an indirect significant impact on the Palo Verde Mesa Groundwater Basin by inducing underflow from the Colorado River to the Palo Verde Mesa Groundwater Basin. Staff believes that inducing flow from the Colorado River into the Palo Verde Mesa Groundwater Basin is a significant impact.

Staff believes that the impact related to outflow could be mitigated such that the project would not contribute to cumulative impacts. **SOIL&WATER-14** and **SOIL&WATER-17** would minimize impacts to the Colorado River below a level of significance.

Groundwater Levels

Compared to the approved PSPP project, the modified PSEGS project would reduce water use both during construction (from 5,750 af to 1,130 af) and during operation (from 300 afy to 201 afy). As a result, the overall water use of PSEGS could be roughly half that of PSPP (7,160 af compared to 14,750 af). The project owner has not revised the groundwater modeling for the modified PSEGS project's water use, therefore staff included the following PSPP groundwater analysis as an overly conservative scenario of groundwater level impacts.

The regional model used by AECOM (2010a) for PSPP is a two-dimensional superposition model developed using MODFLOW code (Harbaugh et al. 2000) for the Parker-Palo Verde-Cibola area, which includes the CVGB and the project site. The model employed a simple vertical geometry and a large grid spacing to evaluate the impacts from groundwater pumping on the Colorado River.

The modeling results suggest (see **Soil & Water Resources Table 23**) that during the life of the foreseeable projects listed in the PSPP RSA (CEC 2010c), groundwater level declines between one and five feet or more could extend a distance of approximately 4 miles from the project ROW. The closest existing well is located within 2 miles of the ROW (see **Soil & Water Resources Figures 16** and **17**). Consequently, staff concluded it is appropriate to assume that the potential impact to water levels in existing wells appears to be cumulatively significant, and require monitoring and mitigation in the event that monitoring indicates significant impacts. PSPP was required to implement Condition of Certification **SOIL&WATER-4** to mitigate any such impacts to groundwater users (wells) due to lowering of the groundwater table. Although PSEGS would result in less water use compared to PSPP, CVGB pumping is still expected to contribute to changes in groundwater levels. The project owner agreed to the same PSPP monitoring, mitigation, and reporting requirements of Condition of Certification **SOIL&WATER-4** be applied to the modified project.

Soil & Water Resources Table 23
Results of Predictive Simulations Numerical Groundwater Model for PSPP and Foreseeable Projects(1)

Model Run 15(1)	T, ft2/d	S	Notes:
Zone 1(2)	1,000	0.2	1. Refer to Soil & Water Resources Table 21 (bottm row) for the water use schedule that was used to run this model. 2. Figure DR-S&W-207-3 shows the areal distribution of transmissivities used in the model
Zone 2(2)	6,300	0.2	
Zone 3(2)	26,000	0.2	

Year	Maximum drawdown (feet)				Change in Storage (af)
	Well 1	Well 2	Well 3	Well 4	
2013	46.59	25.93	46.67	25.96	8,420
2043	11.83	7.50	12.15	8.49	146,837

Groundwater Quality

There is a potential that significant cumulative groundwater quality impacts could occur during construction and operation if contaminated or hazardous materials used during construction and operations were to be released and migrate to the groundwater table.

The modified project would not be expected to cumulatively contribute to the possible long-term operational cumulative impacts, given the distance to the groundwater table (>100 feet bgs) over the CVGB and the proposed implementation of a hazardous material management plan as well as monitoring plans associated with operation of surface impoundments, septic systems and other various operations. With implementation of the Conditions of Certification specified below, cumulative impacts to groundwater quality are anticipated to be below the level of significance.

Surface Water Hydrology

The cumulative impacts of the foreseeable projects on the local surface water hydrology are directly related to proposed onsite grading and the construction and operation of a network of engineered collector/conveyance channels designed for the purpose of protecting the various projects from flooding. The foreseeable projects would change both the extent and physical characteristics of the existing floodplain within each project site as well as downstream of each project site. Sediment transport and depositional characteristics of each of the project sites would also change.

The PSEGS would not be expected to cumulatively contribute to the possible short-term cumulative impacts related to surface water hydrology because the implementation of the Conditions of Certification below would reduce the cumulative impacts below the level of significance.

Surface Water Quality

It is expected that storm water generated on the various project sites may encounter soil or chemicals deleterious to aquatic and terrestrial plant and wildlife. It is expected that all of the projects would be required to implement BMPs for managing potentially harmful storm water and protect water quality. Potentially significant water quality impacts could occur during operations if contaminated or hazardous materials used during operations were to contact storm water and drain offsite. It is expected that all of the projects would have requirements similar to Hazardous Material Management Plans to reduce this potential impact to insignificant.

All of the foreseeable projects would alter natural storm water drainages and the expected use of BMPs would reduce potentially significant impacts related to concentrated drainage and ensuing soil erosion and sediment transport offsite. The PSEGS would not be expected to cumulatively contribute to the possible short-term cumulative impacts related to surface water quality with implementation of the conditions of certification described below.

NON-OPERATION AND FACILITY CLOSURE

PSEGS is designed for an operating life of 25 to 30 years. Operations can cease as a result from two types circumstances: (1) the facility is closed suddenly and/or unexpectedly because of unplanned events, such as a natural disaster or economic forces or (2) the facility is closed in a planned, orderly manner, such as at the end of its useful economic or mechanical life or due to gradual obsolescence. As described in the **GENERAL CONDITONS** section of the FSA, “non-operation” is time-limited (planned or unplanned) that can encompass part or all of the facility, and “closure” is a facility shutdown with no intent to restart operation.

In the event of a temporary closure, PSEGS would be required to comply with all applicable conditions of certification, including a Site Contingency Plan (see Condition of Certification **COM-12**). Depending on the expected duration of the shutdown, appropriate measures would be taken such as removing chemicals from storage tanks or equipment.

Permanent closure requires compliance with a Facility Closure Plan (see Condition of Certification **COM-15**), which would be submitted to the Energy Commission for approval three years prior to actual closure. Future circumstances that could affect permanent closure are largely unknown at this time; however compliance with all applicable LORS, and any local and/or regional plans would be required. The plan must address all concerns in regard to potential erosion and impacts on water quality, as described in Condition of Certification **SOIL&WATER-13**. Refer to the **GENERAL CONDITIONS** section of this FSA for further discussion on temporary and permanent facility closure.

COMPLIANCE WITH LORS AND STATE POLICIES

FEDERAL

Clean Water Act (CWA) of 1977 (Including 1987 Amendments) Sections 401, 402 and 404

The primary objective of the CWA is to restore and maintain the chemical, physical, and biological integrity of the Nation's surface waters. Pollutants regulated under the CWA include "priority" pollutants, including various toxic pollutants; "conventional" pollutants, such as biochemical oxygen demand, total suspended solids, oil and grease, and pH; and "non-conventional" pollutants, including any pollutant not identified as either conventional or priority.

Clean Water Act Section 401

Section 401 of the CWA requires certification from the Colorado River Basin Regional Water Quality Control Board that the PSEGS project is in compliance with established water quality standards. Projects that have the potential to discharge pollutants are required to comply with established water quality objectives. These requirements include the implementation of BMPs during site grading activities and other activities associated with construction of the facility.

Section 401 provides the SWRCB and the CRBRWQCB with the regulatory authority to waive, certify, or deny any proposed federally permitted activity, which could result in a discharge to waters of the State. To waive or certify an activity, these agencies must find that the proposed discharge will comply with state water quality standards. According to the CWA, water quality standards include beneficial uses, water quality objectives/criteria, and compliance with the United States Environmental Protection Agency's (USEPA) anti-degradation policy.

No license or permit may be issued by a federal agency until certification required by Section 401 has been granted. Under the CWA, United States Army Corp of Engineers (USACE) Section 404 permits are subject to CRBRWQCB Section 401 Water Quality Certification (Title 23 CCR Sections 3830 through 3869). As such, a determination of "federal waters" under Section 404 is required by the USACE.

In August 2010, the USACE determined that "federal waters", also known as waters of the U.S., are not present on the approved PSPP project site. This jurisdictional delineation, which is valid for five years, is valid for the PSEGS because the project footprint is located within the area verified by USACE for PSPP. (For further discussion on waters of the U.S., see the **BIOLOGICAL RESOURCES** section of this FSA.)

The CRBRWQCB has authority under the Porter-Cologne Water Quality Control Act of 1967, Water Code Section 13000 et. seq. (Porter-Cologne) to regulate discharge of waste to waters of the state. The definition of the waters of the state is broader than that for waters of the U.S. in that all waters are considered to be a water of the state regardless of circumstances or condition. The term "discharge of waste" is also broadly defined in Porter-Cologne, such that discharges of waste include fill, any material resulting from human activity, or any other "discharge" that may directly or indirectly impact waters of the state relative to implementation of Section 401 of the CWA.

Porter-Cologne authorizes the CRBRWQCB to regulate discharges of waste and fill material to waters of the state, including "isolated" waters and wetlands, through the issuance of waste discharge requirements (WDRs). Under Porter-Cologne all parties proposing to discharge waste that could affect the quality of waters of the state, other than into a community sewer system, shall file with the appropriate CRBRWQCB a Report of Waste Discharge (ROWD) containing such information and data as may be required by the CRBRWQCB. Condition of Certification **SOIL&WATER-6** includes updated Waste Discharge Requirements for operation of the surface impoundments which reflects the project changes of the modified project.

Clean Water Act Section 402

Direct and indirect discharges and storm water discharges into waters of the U.S. must be made pursuant to a National Pollutant Discharge Elimination System (NPDES) permit (CWA Section 402). NPDES permits contain industry-specific, technology-based limits and may also include additional water quality-based limits, and establish pollutant-monitoring requirements. A NPDES permit may also include discharge limits based on Federal or State water quality criteria or standards.

In 1987, the CWA was amended to include a program to address storm water discharges for industrial and construction activities. Storm water discharge is covered by an NPDES permit, either as an individual or general permit. The CRBRWQCB administers the NPDES permit program under the CWA in the project area. The modified project would obtain to a Construction General Permit to meet the Section 402 NPDES requirements.

Clean Water Act Section 404

Activities resulting in the dredging or filling of jurisdictional waters of the U.S. require authorization under a Section 404 permit issued by the USACE. The USACE may grant authorization under either an individual permit or a nationwide permit (NWP) to address operations that may affect the ephemeral washes on the project site. Section 404 permits are also subject to CWA Section 401 water quality certification through the CRBRWQCB. As explained above under the Clean Water Act Section 401, the USACE made a determination that there were no waters of the U.S. present on the PSPP project site. This determination, which is valid for five years, is valid for the PSEGS because the project footprint is located within the area verified by USACE for PSPP.

STATE

The administering agencies for the State LORS are the Energy Commission, the SWRCB, and the CRBRWQCB.

State of California Constitution Article X, Section 2

Article X, Section 2 prohibits the waste or unreasonable use of water, regulates the method of use and method of diversion of water and requires all water users to conserve and reuse available water supplies to the maximum extent possible. The modified project's use of dry cooling would significantly reduce potential water use and prohibit waste and unreasonable use of groundwater.

California Storm Water Permitting Program

California Construction Storm Water Program. Construction activities that disturb one acre or more are required to be covered under SWRCB's NPDES General Permit for Storm Water Discharges Associated with Construction and Land Disturbance Activities, (Order No. 2009-0009-DWQ NPDES No. CAS 000002).

Activities subject to permitting include clearing, grading, stockpiling, and excavation. The General Construction Permit requires the development and implementation of a SWPPP that specifies BMPs that will reduce or prevent construction pollutants from leaving the site in storm water runoff and will also minimize erosion associated with the construction project. The SWPPP must contain site map(s) that show the construction site perimeter; existing and proposed structures and roadways; storm water collection and discharge points, general topography both before and after construction; and drainage patterns across the site.

The modified project would prepare a SWPPP as a requirement of the Construction General Permit. The project would also prepare a DESCP to meet Energy Commission requirements. The content of a DESCP is very similar to a SWPPP, but the DESCP covers both construction and operation in one document whereas separate SWPPPs are prepared for construction and operation.

California Industrial Storm Water Program. Industrial activities with the potential to impact storm water discharges are required to obtain a NPDES permit for those discharges. In California, SWRCB's NPDES General Permit for Discharges of Storm Water Associated with Industrial Activities (Order 97-03-DWQ,NPDES No. CAS 000001) may be issued to regulate discharges associated with ten broad categories of industrial activities, including electrical power generating facilities. The General Industrial Permit requires the implementation of management measures that will protect water quality. In addition, the discharger must develop and implement a SWPPP and a monitoring plan. Through the SWPPP, sources of pollutants are to be identified and the means to manage the sources to reduce storm water pollution described. The monitoring plan requires sampling of storm water discharges during the wet season and visual inspections during the dry season.

A report documenting the status of the program and monitoring results must be submitted to the CRBRWQCB annually by July 1. The General Industrial Permit, which requires the development and implementation of a SWPPP, is required for the project's operations phase. At the present time, the facility does not have a Standard Industrial Classification (SIC) code that would require compliance with the California's Industrial Storm Water Program.

California Water Code

Section 461. Stipulates that the primary interest of the people of the State of California is the conservation of all available water resources and requires the maximum reuse of reclaimed water as an offset to using potable resources. The modified project does not plan to use reclaimed water. However, dry cooling has been proposed and the project would minimize water usage and recycle water where appropriate.

Section 1200 "Water Rights." All water in California falls within one of three categories: surface water, percolating groundwater, or "subterranean streams that flow through known and definite channels." California's water rights law is a hybrid system in that the use of certain types of water requires a permit from the SWRCB, while other types of uses are governed by common law. Only surface water and subterranean stream water are within the permitting jurisdiction of the SWRCB. Since 1914, appropriation of those waters has required a SWRCB permit, and is subject to various permit conditions.

Interstate water courses (such as the Colorado River) have additional contract requirements that are the equivalent of permits. For example, use of Colorado River water requires a contract with the Secretary of the Interior (through the USBR).

Pre-1914 appropriative and riparian rights do not require a permit. Riparian rights are correlative rights of equal priority among all riparian right holders. The place of use of such water is limited to riparian property (property that is contiguous to a watercourse) that has not had its riparian rights severed. Riparian rights are senior to any appropriative rights, and may not be separated from the riparian parcel and used elsewhere.

Groundwater can be (a) the underground portion of a surface water course (subject to the same rights/permits as the affiliated water course); (b) a wholly underground water course which is treated like a water course; or (c) percolating groundwater. Water subject to appropriation is defined in Water Code Section 1201, as "all water flowing in any natural channel," except water that is or may be needed for use upon riparian land or water that is otherwise appropriated. The SWRCB's authority over groundwater extends only to the underground portion of a surface stream and to the water in un-appropriated subterranean streams that flow through known or defined channels, except as it is or may reasonably be needed for useful and beneficial purposes upon lands riparian to the channel through which it is flowing. The traditional test to establish SWRCB jurisdiction over groundwater was whether there is sufficient evidence of bed and banks and water flowing along a line of a surface stream (Sax 2002).

Recent case law has redefined the boundaries of an underground stream to mean the bedrock bottom and side boundaries that are materially less permeable than the alluvium holding groundwater found within an alluvial valley across which flows a surface stream. If there is insufficient evidence to support a finding that the groundwater fits this definition, the SWRCB has no jurisdiction and no permit is required to appropriate the water.

Percolating groundwater has no SWRCB permit requirement and supports two kinds of rights: (a) overlying rights, a correlative right of equal priority shared by all who own overlying property and use groundwater on the overlying property; and (b) groundwater appropriative rights for use of the overlying property or on overlying property for which the water rights have been severed. The right to use groundwater on property that is not as an overlying right is junior to all overlying rights, but has priority among other appropriators on a first in time use basis. Overlying users cannot take unlimited quantities of water without regard to the needs of other users. Surplus groundwater may be appropriated for use on non-overlying lands, provided such use will not create an overdraft condition.

Riparian water rights, groundwater rights and appropriative rights are all subject to modification to some degree if there is a basin-wide adjudication, which proceeding can be commenced before the SWRCB as an adjudicative body (not a permitting role) or before a Court. In adjudication, unused riparian rights and unused overlying rights can be subordinated to appropriative rights.

Water rights in California can be held by any legal entity. Thus the owner can be an individual, related individuals, non-related individuals, trusts, corporations and/or government agencies. Water rights are considered real property. Riparian rights and overlying groundwater rights are lost if severed from the land, while appropriative rights can be preserved and transferred to other properties. Transfers of water for use elsewhere are permissible without transfers of water rights, subject to many other conditions and approvals, including a "non-injury" to other water rights holders test, assessment of environmental impacts, and for post 1914 appropriative rights, SWRCB approval of any change in place of use, diversion point and/or purpose of use.

The California Water Code allows any local public agency that provides water service whose service area includes a groundwater basin or portion thereof that is not subject to groundwater management pursuant to a judgment or other order, to adopt and implement a groundwater management plan (California Water Code Sections 10750 et. seq.) Groundwater Management Plans often require reports of pumping and some restrictions on usage. There is no Groundwater Management Plan for the Chuckwalla Valley Ground Water Basin (CVGB) listed on the DWR website on Groundwater Management Plans.

The California Legislature has found that by reason of light rainfall, concentrated population, the conversion of land from agricultural to urban uses and heavy dependence on groundwater, the counties of Riverside, Ventura, San Bernardino and Los Angeles have certain reporting requirements for groundwater pumping. Any person or entity that pumps in excess of 25 af of water in any one year must file a "Notice of Extraction and Diversion of Water" with the SWRCB. (See Water Code Sections 4999 et. seq.) The project would be subject to this requirement since it is located in Riverside County and would require more than 25 afy. Condition of Certification **SOIL&WATER-15** would ensure the project owner complies with Section 1200 “Water Rights” requirement.

The project is in Riverside County and the Chuckwalla Valley has no perennial streams. The project site is located on BLM land that overlies the CVGB, which has a surface area of about 822,000 acres. A method was developed by the USGS, in cooperation with the USBR, to identify groundwater wells outside the flood plain of the lower Colorado River that yield water that will be replaced by water from the river. Wells placed into the groundwater beneath the project site that extract groundwater may be considered as drawing water from the Colorado River and require an entitlement to extract groundwater. The specific method to determine whether wells draw water from the Colorado River (referred to as the accounting surface) has not been promulgated by the USBR. Entitlements to extract and use the groundwater beneath the site are granted by the USBR through their designated representative in California, the Colorado River Board of California. After eligibility for groundwater extraction has been approved by the USBR, a contract must be established with the City of Needles to acquire the water. In California, the City of Needles monitors the use of water extracted from the river aquifer and is the designated contracting agent for the USBR.

Porter-Cologne Water Quality Control Act

The Porter-Cologne Water Quality Control Act of 1967, Water Code Section 13000 et. seq. requires the SWRCB and the nine RWQCBs to adopt water quality standards to protect State waters. Those standards include the identification of beneficial uses, narrative and numerical water quality criteria, and implementation procedures. Water quality standards for the proposed modified project area are contained in the Water Quality Control Plan for the Colorado River Basin Region (Basin Plan), which was adopted in 1994 and was amended in 2006. This plan sets numeric and/or narrative water quality criteria controlling the discharge of wastes to the State's waters and land.

Title 23 CCR Division 3, Chapters 9 and 15 regards the establishment of requirements for waste discharge and reporting along with requirements specifying conditions for the protection of water quality. Under Chapter 9, the CRBRWQCB is required to issue a ROWD for discharges of waste to land pursuant to the Water Code. The report requires the submittal of information regarding the proposed discharge and waste management unit design and monitoring program. WDRs issued by the CRBRWQCB provide construction and monitoring requirements for the proposed discharge. Chapter 15 outlines siting, construction, and monitoring requirements for waste discharges to land for landfills, surface impoundments, land treatment units, and waste piles. The Chapter provides closure and post-closure maintenance and monitoring requirements for Class II designated waste facilities that are applicable to this project.

Section 13050. Surface waters (including ephemeral washes) that are affected by the Project are waters of the State and are subject to State requirements and the CRBRWQCB's authority to issue WDRs for construction and industrial storm water activities.

Section 13260 et seq. This section requires filing with CRBRWQCB a ROWD for activities in which waste is discharged that could affect the water quality of the State. The report shall describe the physical and chemical characteristics of the waste and include the results of all tests required by regulations adopted by the board, any test adopted by the California Department of Toxic Substances Control (DTSC) pursuant to Section 25141 of the Health and Safety Code for extractable, persistent, and bioaccumulative toxic substances in a waste or other material, and any other tests that the SWRCB or CRBRWQCB may require. In accordance with Water Code Section 13263, the [State Water Board / Regional Water Board] hereby "prescribes" the waste discharge requirements as adopted by the Energy Commission for the Project. Because the Energy Commission has exclusive permitting authority over the project under Public Resources Code section 25500, the State Board "prescribes" the waste discharge requirements for the sole purpose of authorizing the Regional Board to enforce them and undertake associated monitoring, inspection, and annual fee collection as if the waste discharge requirements were adopted by the Board.

Section 13173 (Designated Wastes). Traditionally the State Water Resources Control Board along with the applicable California Regional Water Quality Control Board (hereafter "Water Boards") develop, adopt, and enforce waste discharge requirements for facilities that discharge waste. When such a facility is an electrical generating facility under the Energy Commission's jurisdiction, however, the Energy Commission permit takes the place of the Water Boards' permit and the WDRs are folded into the Energy Commission's conditions of certification. Nevertheless, Energy Commission staff believe it is important to have the Water Boards retain the authority to enforce these requirements, along with the authority to monitor, inspect, and collect an annual fee, because they are state and local agencies with expertise in this subject area. Therefore, staff recommends that the Energy Commission delegate this authority the Water Boards pursuant to title 20, California Code of Regulations, section 1770(b), and has provided language to that effect in Condition of Certification **SOIL&WATER-6.** The Water Boards may also take action in tandem with delegation by the Energy Commission to prescribe the requirements adopted by the Energy Commission to ensure that their agents are fully informed and authorized to enforce the WDRs in the Commission's decision.

This section defines designated waste as either: a) hazardous waste that has been granted a variance from hazardous waste management requirements pursuant to Section 14142 of the Health and Safety Code, or, b) Non-hazardous waste that consists of, or contains, pollutants that, under ambient environmental conditions at a waste management unit, could be released in concentrations exceeding applicable water quality objectives or could reasonably be expected to affect beneficial uses of the waters of the state contained in the appropriate state water quality control plan.

Section 13240 et seq. (Water Control Plan). The Basin Plan for the Colorado River Basin Region establishes water quality objectives, including narrative and numerical standards that protect the beneficial uses of surface and ground waters in the region. The Basin Plan describes implementation plans and other control measures designed to ensure compliance with statewide plans and policies and provide comprehensive water quality planning. The following chapters are applicable to determining appropriate control measures and cleanup levels to protect beneficial uses and to meet the water quality objectives: Chapter 2, Beneficial Uses; Chapter 3, Water Quality Objectives; and the sections of Chapter 4, Implementation, entitled “Point Source Controls” and “Non-Point Source Controls.”

- Beneficial Uses: Chapter 2 of the Basin Plan describes beneficial uses of surface and ground waters. Beneficial uses of surface waters for the Chuckwalla Valley are not listed in the Basin Plan. The beneficial uses of ground waters of the Chuckwalla Valley Hydrologic Unit (717.00) are: municipal and domestic supply, industrial service supply, and agricultural supply.
- Water Quality Objectives: Region-wide numeric and narrative objectives for general surface waters are described in Chapter 3 of the Basin Plan under the “General Surface Water Quality Objectives” and region-wide objectives for groundwater under the “Ground Water Objectives.”
- Waste Discharge Requirements: Chapter 4 of the Basin Plan describes “Point-Source Controls” for wastewater reclamation and reuse, storm water, and septic systems. The discussion of “Non-Point Source Controls” in the Basin Plan describes the authority given to the CRBRWQCB to certify projects for CWA Section 401 permits.

Section 13243. Under this section, the Regional Water Boards are granted authority to specify conditions or areas where the discharge of waste will not be permitted. The discharge of designated waste can only be discharged to an appropriately designed waste management unit.

Section 13263 (Waste Discharge Requirements). The CRBRWQCB regulates the discharges of fill material, including structural material and/or earthen wastes into wetlands and other waters of the State through WDRs. The CRBRWQCB considers WDRs necessary to adequately address potential and planned impacts to waters of the State and to require mitigation for these impacts to comply with the water quality standards specified in the Basin Plan. Condition of Certification **SOIL&WATER-6** would ensure the applicant complies with this requirement.

Section 13271 (Discharge Notification). CWC section 13271 requires any person who, without regard to intent or negligence, causes or permits any hazardous substance or sewage to be discharged in or on any waters of the state, or discharge or deposited where it is, or probably will be, discharged in or on any waters of the state to notify the Office of Emergency Services (OES) of the discharge as specified in that section. The OES then immediately notifies the appropriate regional board and the local health officer and administrator of environmental health of the discharge.

Section 13550. “The Legislature hereby finds and declares that the use of potable domestic water for non-potable uses, including, but not limited to, cemeteries, golf courses, parks, highway, landscaped areas, and industrial and irrigation uses, is a waste or an unreasonable use of the water within the meaning of Section 2 of Article X of the California Constitution if recycled water is available which meets all of the following conditions, as determined by the State Board.” This section requires the use of recycled water for industrial purposes subject to recycled water being available and upon a number of criteria including: provisions that the quality and quantity of the recycled water are suitable for the use, the cost is reasonable, the use is not detrimental to public health, and the use will not impact downstream users or biological resources.

The project would not be subject to this policy because it has no nearby sources of municipal recycled water. However, the project proposes to supplement its groundwater supply with recycled water produced from onsite wastewater treatment using a thermal evaporator system.

Section 13551. This section prohibits a person or public agency, including a State agency, city, county, city and county, district, or any other political subdivision of the State, from using water from any source of quality suitable for potable domestic use for non-potable uses if suitable recycled water is available as provided in Section 13550. The project would not be subject to this policy because it has no nearby sources of municipal recycled water.

Section 13552. This section specifically identifies the use of potable domestic water for cooling towers as an unreasonable use of water within the meaning of Article X Section 2 of the California Constitution, if suitable recycled water is available and the water meets the requirements set forth in Section 13550. The project would not be subject to this policy because it has no nearby sources of municipal recycled water.

Section 13571. Requires that anyone who constructs, alters, or destroys a water well, cathodic protection well, groundwater monitoring well, or geothermal heat exchange well, file a well completion report with the California Department of Water Resources (CDWR). With no nearby sources of water available and no existing water supply wells on the project site, a water supply well and groundwater monitoring wells would be constructed at the site. These wells are required as part of the evaluation of water resources for the project. A well completion report would be filed with DWR for each well that is constructed. Measures would be undertaken to protect the groundwater wells (whether for water supply or for monitoring purposes) on the project site through the use of physical barriers (e.g., fencing, traffic bollards, etc.). In the event that an existing well is altered or destroyed, a well completion report would be filed with the DWR.

California Code of Regulations

Title 22, Article 3, Sections 64400.80 through 64445. This section requires monitoring for potable water wells, defined as non-transient, non-community water systems (serving 25 people or more for more than six months). The project would be subject to this requirement, because it would employ approximately 100 workers during operations. Regulated wells must be sampled for bacteriological quality once a month and the results submitted to the California Department of Public Health (CDPH). The wells must also be monitored for inorganic chemicals once and organic chemicals quarterly during the year designated by the CDPH. CDPH will designate the year based on historical monitoring frequency and laboratory capacity. Condition of Certification **SOIL&WATER-15** would ensure the project owner complies with requirements of non-transient, non-community water systems.

Title 23, Division 3, Chapter 9. This chapter requires the CRBRWQCB to issue a report of waste discharge for discharges of waste to land pursuant to the Water Code. The report requires submittal of information regarding the proposed discharge and waste management unit design and monitoring program. WDRs issued by the CRBRWQCB provide construction and monitoring requirements for the proposed discharge. The SWRCB has adopted general waste discharge requirements (97-10-DWQ) for discharge to land by small domestic wastewater treatment systems. Condition of Certification **SOIL&WATER-6** would meet the requirements of a report of waste discharge for discharges of waste to land and obtain waste discharge requirements.

With respect to onsite wastewater discharge, the CRBRWQCB adopted in 1984 “Guidelines for Sewage Disposal from Land Developments” that provides exclusion of on-site sanitary wastewater flows less than 5,000 gallons per day. Based on the estimate of approximately 3,010 gallons per day of sanitary wastewater spread out among three or more locations, the exclusion applies. Condition of Certification **SOIL&WATER-7** would ensure the sanitary wastewater disposal systems meet County of Riverside requirements.

Title 23, Division 3, Chapter 15. Regulates all discharges of hazardous waste to land that may affect water quality. Chapter 15 broadly defines a waste management area as “an area of land, or a portion of a waste management facility, at which waste is discharged.” Therefore, unless exempted, all discharges of hazardous waste to land that may affect water quality are regulated by Chapter 15. This chapter outlines siting, construction and monitoring requirements for waste discharges to land for landfills, surface impoundments, land treatment units, and waste piles. The chapter provides closure and post-closure maintenance and monitoring requirements for surface impoundments that are applicable to the project.

State Water Resources Control Board Policies

Anti-Degradation Policy (Resolution No. 68-16). Requires the CRBRWQCB, in regulating the discharge of waste, to: (a) maintain existing high quality waters of the State until it is demonstrated that any change in quality will be consistent with maximum benefit to the people of the State, will not unreasonably affect present and anticipated beneficial uses, and will not result in water quality less than that described in State or Regional Water Boards policies; and (b) require that any activity which produces or may produce a waste or increased volume or concentration of waste and which discharges or proposes to discharge to existing high quality waters, must meet waste discharge requirements which will result in the best practicable treatment or control of the discharge necessary to assure that: a) a pollution or nuisance will not occur and b) the highest water quality consistent with maximum benefit to the people of the State will be maintained. Conditions of Certification **SOIL&WATER-1**, **-6**, **-7**, **-18**, and **-20** would protect the quality of groundwater and surface water.

Power Plant Cooling Water Policy (Resolution No. 75-58). On June 19, 1975, the SWRCB adopted the Water Quality Control Policy on the Use and Disposal of Inland Waters used for Power Plant Cooling. The purpose of the policy is to provide consistent statewide water quality principles and guidance for adoption of discharge requirements, and implementation actions for power plants that depend on inland waters for cooling. State policy encourages the use of wastewater for power plant cooling and sets the following order of preference for cooling purposes: 1) wastewater being discharged to the ocean; 2) ocean water; 3) brackish water or irrigation return flows; 4) inland waste waters of low total dissolved solids (TDS); and 5) other inland waters. The criteria for the selection of water delivery options involves economic feasibility; engineering constraints, such as cooling water composition and temperature; and environmental considerations such as impacts on riparian habitat, groundwater levels, and surface and subsurface water quality.

The project would use dry-cooling methods and does not propose to use groundwater for power plant cooling. The project would use groundwater for mirror washing, auxiliary equipment cooling, process makeup, dust suppression, and potable supply.

Water Reclamation Policy (Resolution No. 77-01). Under this policy, the SWRCB and CRBRWQCBs shall encourage reclamation and reuse of water in water-short areas. Reclaimed water will replace or supplement the use of fresh water or better quality water. The project would not be subject to this policy because it has no nearby sources of municipal recycled water. However, the project proposes to supplement its groundwater supply with recycled water produced from onsite wastewater treatment using a thermal evaporator system.

Policies and Procedures for Investigations and Clean-up and Abatement of Discharges Under CWC Section 13304 (Resolution No. 92-49). This policy establishes requirements for investigation and cleanup and abatement of discharges. Under this policy, clean-up and abatement actions are to implement applicable provisions of Title 23 CCR Chapter 15, to the extent feasible. The policy also requires the application of Section 2550.4 of Chapter 15 when approving any alternative cleanup levels less stringent than background. It requires remediation of the groundwater to the lowest concentration levels of constituents technically and economically feasible, which must at least protect the beneficial uses of groundwater, but need not be more stringent than is necessary to achieve background levels of the constituents in groundwater. The project is not likely to be subject to this requirement because a Phase 1 Environmental Site Assessment conducted in 2009 concluded that no recognized environmental conditions (such as contaminated soil) were associated with the project site.

Water Quality Control Policy for Recycled Water (Resolution No. 209-0011). The Recycled Water Policy is intended to promote sustainable local water supplies. The purpose of this Policy is to increase the use of recycled water from municipal wastewater sources that meets the definition in CWC Section 13050(n), in a manner that implements state and Federal water quality laws. The project would not be subject to this policy because it has no nearby sources of municipal recycled water. However, the project proposes to supplement its groundwater supply with recycled water produced from onsite wastewater treatment using a thermal evaporator system.

Public Resources Code

Section 25300 et seq. In the 2003 "Integrated Energy Policy Report", consistent with SWRCB Policy No. 75-58 and the Warren-Alquist Act, the Energy Commission adopted a policy stating they would approve the use of "fresh inland" water for cooling purposes by power plants only where alternative water supply sources and alternative cooling technologies are shown to be "environmentally undesirable" or "economically unsound." The project does not propose to use groundwater for power plant cooling. The project would use dry-cooling methods and does not propose to use groundwater for power plant cooling. The Project would use groundwater for mirror washing, auxiliary equipment cooling, process makeup, dust suppression, and potable supply.

Project Compliance with State Water Policy

The Energy Commission has five authoritative sources for statements of policy relating to water use in California applicable to power plants. They are the California Constitution, the Warren-Alquist Act, the Commission's restatement of the state's water policy in the 2003 Integrated Energy Policy Report ("IEPR"), the State Water Resources Control Board ("SWRCB" or "Board") resolutions (in particular Resolutions 75-58 and 88-63), and a letter from the Board to the Energy Commission interpreting Resolutions 75-58 and 88-63 [collectively referred to as the state's water policies - see Genesis Solar Project (09-AFC-08)].

California Constitution

California's interest in conserving water is so important to our thirsty state that in 1928, the common law doctrine of reasonable use became part of the state Constitution. Article X, section 2 calls for water to be put to beneficial use, and that "waste or unreasonable use or unreasonable *method of use* be prevented." (Cal. Const., art. X, § 2; emphasis added.) The article also limits water rights to reasonable use, including reasonable methods of use. (*Ibid*.) Even earlier in the 20th Century, a state Supreme Court case firmly established that groundwater is subject to reasonable use. (*Katz v. Walkinshaw* (1903) 141 Cal. 116.) Thus, as modern technology has made dry-cooling of power plants feasible, the Commission may regard wet-cooling as an unreasonable method of use of surface or groundwater, and even as a wasteful use of the state's most precious resource.

Warren-Alquist Act

Section 25008 of the Commission's enabling statutes echoes the Constitutional concern, by promoting "all feasible means" of water conservation and "all feasible uses" of alternative water supply sources. (Pub. Resources Code § 25008.)

Integrated Energy Policy Report

In the 2003 Integrated Energy Policy Report ("IEPR" or "Report"), the Commission reiterated certain principles from SWRCB's Resolution 75-58, discussed below, and clarified how they would be used to discourage use of fresh water for cooling power plants under the Commission's jurisdiction. The Report states that the Commission will approve the use of fresh water for cooling purposes only where alternative water supply sources or alternative cooling technologies are shown to be "'environmentally undesirable'" or "'economically unsound.'" (IEPR (2003), p. 41.) In the Report, the

Commission interpreted “environmentally undesirable” as equivalent to a “significant adverse environmental impact” under CEQA, and “economically unsound” as meaning “economically or otherwise infeasible,” also under CEQA. (IEPR, p. 41.) CEQA and the Commission’s siting regulations define feasible as “capable of being accomplished in a successful manner within a reasonable amount of time,” taking into account economic and other factors. (Cal. Code Regs., tit. 14, §15364; tit. 20, §1702, subd. (f).) At the time of publication in 2003, dry cooling was already feasible for three projects—two in operation and one just permitted. (IEPR, p. 39.)

The Report also notes California’s exploding population, estimated to reach more than 47 million by 2020, a population that will continue to use “increasing quantities of fresh water at rates that cannot be sustained.” (IEPR, p. 39.)

State Water Resources Control Board Resolutions

The SWRCB not only considers quantity of water in its resolutions, but also the quality of water. In 1975, the Board determined that water with total dissolved solids (“TDS”) of 1,000 mg/l or less should be considered fresh water. (Resolution 75-58.) One express purpose of that Resolution was to “keep the consumptive use of fresh water for powerplant cooling to that *minimally essential*” for the welfare of the state. (*Ibid*; emphasis added.) In 1988, the Board determined that water with TDS of 3,000 mg/l or less should be protected for and considered as water for municipal or domestic use. (Resolution 88-63.)

Discussion

The project proposes a dry-cooled facility that would use 201 afy of groundwater from onsite wells. Groundwater is the only available source of water. Pumped water would be used for various purposes, including domestic use by workers, dust suppression, and mirror washing. Water is the only feasible means of cleaning the mirrors, which must be clean to maintain efficiency of output by solar plants. Process makeup water would be recycled to supplement groundwater supplies. Overall use of the water is efficient for this technology, requiring about 40 afy per 100 MW of capacity.

Quality of the groundwater varies significantly throughout the Chuckwalla Valley groundwater basin, and varies with depth. In general, groundwater below the project site would not meet water quality standards for domestic supply without treatment, because of high concentrations of fluoride and sulfate. Staff concludes that the modified PSEGS project complies with the state’s water policies to feasibly use the least amount of the lowest-quality water available.

REGIONAL AND LOCAL

Riverside County Ordinance Codes, Title 13, Chapter 13.20 – Water Wells

Section 13-.20.160 Well Logs. This section requires that a report of well excavation for all wells dug or bored for which a permit has been issued be submitted to the Riverside County Department of Environmental Health within 60 days after completion of drilling.

Section 13.20.190 Water Quality Standards. This section requires that water from wells that provide water for beneficial use shall be tested radiologically, bacteriologically and chemically as indicated by the Riverside County Department of Environmental Health. Laboratory testing must be performed by a State of California-certified laboratory. The results of the testing shall be provided to the County Department of Environmental Health within 90 days of pump installation.

Section 13.20.220 Well Abandonment. This section provides that all abandoned wells shall be destroyed in such a way that they will not produce water or act as a channel for the interchange of water, and will not present a hazard to the safety and well-being of people or animals. Destruction of any well shall follow requirements stipulated in DWR Bulletin No.74-81, provided that at a minimum the top 50 feet shall be sealed with concrete, or other approved sealing material. Applications for well destruction must be submitted 90 days following abandonment of the well and in accordance with Section 14.08.170.

Section 13.20.240 Declaration of Proposed Reuse. Requires that any well that has not been used for a period of one year shall be properly destroyed unless the owner has filled a “Notice of Intent” with the health officer declaring the well out of service and declaring his intention to use the well again.

Condition of Certification **SOIL&WATER-15** would ensure the project owner complies with requirements to construct and operate groundwater wells.

Riverside County Ordinance Code, Title 8, Chapter 8.124 – Sewage Discharge

Section 8.124.030, General Requirements for an Approval and Construction Permit. The type, capacity, location, and layout of each private system shall comply with the rules and regulations of the health officer, and the WDRs of the CRBRWQCB. A private system shall be constructed and maintained on the lot which is the site of the building it serves, unless the health officer in his discretion authorizes a different location.

Section 8.124.050 Operation Permits. Each private system shall be managed, cleaned, regulated, repaired, modified and replaced from time to time by the owner or owner’s representatives, in accordance with the rules, regulations and other reasonable requirements of the health officer in conformity with the WDR issued by the regional board and in a manner which will safeguard against and prevent pollution, contamination or nuisance.

Condition of Certification **SOIL&WATER-7** would ensure the sanitary wastewater disposal systems meet County of Riverside requirements.

Riverside County Title 15 Chapter 15.24 Uniform Plumbing Code

Section 15.24.010. Adopted by Reference, Appendix K, Section K1 amended – Private Sewage Disposal – General. In certain areas of the County which have poor soils or other problems relative to sewage disposal, the sewage disposal system shall be installed and inspected before the building foundation inspection is made.

Section 15.24.010. Adopted by Reference, Appendix K, Section K6(i) amended – Disposal fields. Disposal fields, trenches, and leaching beds shall not be paved over or covered by concrete or any material that can reduce or inhibit any possible evaporation of the sewer effluent unless the area of the disposal fields, trenches, and leaching beds is increased by a minimum of 25%.

Condition of Certification **SOIL&WATER-7** would ensure the sanitary wastewater disposal systems meet County of Riverside requirements.

Riverside County Title 15 Chapter 15.80 Regulating Flood Hazard Areas and Implementing the National Flood Insurance Program

This ordinance was developed to comply with Title 44 CFR Part 65 regarding requirements for the identification and mapping of areas identified as Federal Emergency Management Agency (FEMA) Special Flood Hazard Areas. The ordinance is applicable to development within unincorporated areas of Riverside County and is integrated into the process of application for development permits under other county ordinances including, but not limited to, Ordinance Nos. 348, 369, 457, 460, and 555. When the information required, or procedures involved, in the processing of such applications is not sufficient to assure compliance with the requirements of Chapter 15.80, a separate application must be filed.

Flood insurance rate maps for the project site or surrounding areas have not been prepared by FEMA. According to the Riverside County General Plan (Riverside County 2000) the project site and surrounding lands do not lie within a 100-year or 500-year flood plain. Therefore, the project would not be subject to these requirements.

NOTEWORTHY PUBLIC BENEFITS

No noteworthy public benefits of the proposed modified project were identified associated with soil and water resources.

RESPONSE TO COMMENTS

STATE OF CALIFORNIA, ENERGY RESOURCES CONSERVATION AND DEVELOPMENT COMMISSION/BASIN AND RANGE WATCH, LAURA CUNNINGHAM AND KEVIN EMMERICH, STATUS REPORT NO. 1, TN # 70178, MARCH 29, 2013

Comment #1: The commenter states that project groundwater pumping could impact groundwater-dependent vegetation and asks if staff and project owner would agree to a “stop pumping trigger” of groundwater if negative impacts are detected.

Response: Because the PSEGS project would use a reduced amount of water during both construction and operation activities with the same proposed groundwater supply system as the approved PSPP project, staff believes the current Conditions of Certification for mitigation of groundwater level impacts are appropriate. Therefore this does not constitute a need for a project change from the approved project. Condition of Certification **SOIL&WATER-4** does not include a “stop pumping trigger”, but does require groundwater level monitoring, mitigation, and reporting. To mitigate potential impacts to groundwater-dependent vegetation, PSEGS would be required to comply with Conditions of Certification **BIO-23** (Groundwater Dependent Vegetation Monitoring) and **BIO-24** (Remedial Action and Compensation for Adverse Effects to Groundwater-Dependent Biological Resources).

Comment #2: The commenter states that a regional groundwater study should be completed to evaluate the cumulative impacts to both groundwater and the Colorado River Basin relating to large industrial scale energy projects being built in the region.

Response: Because the PSEGS project would use a reduced amount of water during both construction and operation activities with the same proposed groundwater supply system as the approved PSPP project, staff believes the current Conditions of Certification for mitigation of groundwater level impacts are appropriate. Therefore, this does not constitute a need for a project change from the approved project. To mitigate the project's contribution to impacts to the Colorado River, Condition of Certification **SOIL&WATER-14** and **-17** would require entitlements or offsets to Lower Colorado River water.

VEENA DOIJODE, PUBLIC COMMENT RE: IMPACT TO APN 810311009, TN # 70449, APRIL 22, 2013:

Comment: The commenter requests an impact assessment to a parcel (APN 810311009) located close to the project site. The commenter intends to grow palm dates on this land.

Response: The private parcel referenced in the comment is located 5.3 miles southeast of the PSEGS project site, midway between the PSEGS and the Genesis Solar Electric Generating Project. Because the PSEGS project is being processed as an amendment, staff analyzed baseline conditions from the time the original PSPP project was filed, in 2009. At that time, PSPP groundwater pumping was estimated to lower groundwater levels approximately 0.1 ft in the general area of the parcel in question at the end of 30 years of operation (see **Soil & Water Resources Figure 14**). Because future groundwater levels could not be accurately quantified until actual long-term groundwater production occurs, Conditions of Certification **SOIL&WATER-2** through **SOIL&WATER-5** were required to minimize potential impacts. The modified PSEGS project would use less water during both construction and operation activities with the same proposed groundwater supply system as the approved PSPP project. As a result, staff believes that PSEGS would have less impact to groundwater levels for the parcel in question. Conditions of Certification **SOIL&WATER-2** through **SOIL&WATER-5** as approved in the Commission Decision would also mitigate impacts caused by the modified PSEGS project.

GALATI BLEK LLP MARIE FLEMING/PALEN SOLAR HOLDINGS, LLC'S INITIAL COMMENTS ON THE PRELIMINARY STAFF ASSESSMENT, TN # 71551, JULY 11, 2013:

Comment #1: The commenter states that staff did not include Waste Discharge Requirements (WDRs) in the Preliminary Staff Assessment [PSA (CEC 2013r)].

Response: Proposed WDRs, as a required in **SOIL&WATER-6**, have been included in this FSA as Appendices B, C, and D. Staff continues to coordinate with CRBRWQCB to ensure these WDRs would be appropriate for PSEGS.

Comment #2: The commenter proposes a modification to the verification of **SOIL&WATER-17**.

Response: Staff agrees to the modification.

Comment #3: The commenter states that the requirement in **SOIL&WATER-17**, that all fencing be designed to withstand a 100-year storm event, is not feasible. PSH proposes modifications to implement a fence inspection and repair program instead.

Response: Staff agrees to the modifications.

Note: The commenter resubmitted the same comments on July 29, 2013 (TN# 200077).

STATE OF CALIFORNIA, ENERGY RESOURCES CONSERVATION AND DEVELOPMENT COMMISSION/CENTER FOR BIOLOGICAL DIVERSITY, LISA T. BELENKY, COMMENTS ON THE PRELIMINARY STAFF ASSESSMENT, TN # 200055, JULY 29, 2013:

Comment #1: The commenter states that project groundwater pumping would impact groundwater-dependent vegetation and believes the proposed mitigation measures are "too weak because they would require nearly impossible to obtain proof that specific water drawdown was unequivocally caused by the proposed project".

Response: Because the PSEGS project would use a reduced amount of water during both construction and operation activities with the same proposed groundwater supply system as the approved PSPP project, staff believes the current Conditions of Certification for mitigation of groundwater level impacts are appropriate. Therefore this does not constitute a need for a project change from the approved project. To mitigate potential impacts to groundwater-dependent vegetation, PSEGS would be required to comply with Conditions of Certification **BIO-23** (Groundwater Dependent Vegetation Monitoring) and **BIO-24** (Remedial Action and Compensation for Adverse Effects to Groundwater-Dependent Biological Resources).

Comment #2: The commenter states that cumulative impacts to groundwater-dependent vegetation should be updated to include the Eagle Mountain Pumped Storage Project which received SWQCB approval in July 2013.

Response: The cumulative analysis in the PSA (CEC 2013r) included the Eagle Mountain Pumped Storage Project as a reasonable foreseeable project. Its expected water use was based on information in the project's application to the Federal Energy Regulatory Commission. The cumulative analysis was updated for this FSA, and includes the Eagle Mountain Pumped Storage Project with expected water use based on information in the project's Final Environmental Impact Report (EIR).

Comment #3: The commenter states that additional information is needed on the effects of groundwater pumping on nearby seeps and springs in the adjacent Wilderness and Joshua Tree National Park. Also, because of the substantial evaporation rate at the project site, the environmental review should provide data on how much pumped groundwater will actually be returned to the groundwater basin versus that lost to evaporation.

Response: Because the PSEGS project would use a reduced amount of water during both construction and operation activities with the same proposed groundwater supply system as the approved PSPP project, staff believes the current Conditions of Certification for mitigation of groundwater level impacts are appropriate. Therefore this does not constitute a need for a project change from the approved project.

Comment #4: Comments related to Waters of the State and Cryptobiotic Soils were included under the heading "L. Soils and Water Resources".

Response: These topics are covered in the **BIOLOGICAL RESOURCES** section of this FSA.

COLORADO RIVER BOARD OF CALIFORNIA, TANYA M. TRUJILLO, COMMENT LETTER ON THE PRELIMINARY STAFF ASSESSMENT, TN # 200058, JULY 29, 2013:

Comment: The commenter supports the inclusion of Condition of Certification **SOIL&WATER-14** and suggests that the most efficient process for obtaining a legal and reliable water supply would be for the PSEGS owners to enter into an agreement with an entity that currently holds an existing contract for the use of Colorado River Water.

Response: Staff appreciates the support of CRB for the inclusion of Condition of Certification **SOIL&WATER-14**. Staff acknowledges CRB's request that staff prioritize mitigation that would offset water use from a Colorado River water rights contract holder. Staff believes this may be appropriate but the basis for the recommended condition of certification was for mitigation of potential environmental impacts. Therefore staff must also provide for mitigation options in the condition of certification such as the tamarisk removal or other water conservation programs that could achieve the same or similar benefits as the purchase of actively used Colorado River water rights. Staff will consult with CRB to provide review and comment when the Water Offset Plan required in Condition of Certification **SOIL&WATER-14**.

CONCLUSIONS

Staff's conclusions based on analysis of the information are as follows:

1. The project would be located on an alluvial fan where flash flooding and mass erosion could impact the project. A Draft Drainage, Erosion, and Sedimentation Control Plan (DESCP), as required of Condition of Certification **SOIL&WATER-1**, would mitigate the potential storm water and sediment project-related impacts by implementing Best Management Practices (BMPs) during construction and operations. Condition of Certification **SOIL&WATER-20** would reduce damage caused by potential flash flooding.

2. The PSEGS would have an impact on levels of groundwater in the Chuckwalla Valley Groundwater Basin (CVGB). However, the calculations and assumptions used to evaluate potential groundwater level impacts are imprecise and have limitations and uncertainties associated with them such that the magnitude of potential impacts that could occur cannot be determined precisely. To ensure that the project's proposed use of groundwater does not significantly impact the groundwater levels in the CVGB, staff believes the project owner should be required to develop a monitoring program and identify what changes are occurring in basin water levels. Substantial changes to groundwater levels caused by the project and other pumping in the basin would be documented by this monitoring and reporting program and mitigation would be required in accordance with Conditions of Certification **SOIL&WATER-2, -3**, **-4**, and **-5**.These measures will be sufficient to ensure that significant impacts to groundwater levels do not occur.

3. A cumulative impact analysis indicates that groundwater extraction during construction and operation of this and other foreseeable projects would place the basin into an overdraft condition. This impact may be exacerbated by other unidentified renewable energy projects in the I-10 corridor, which has been targeted as a potential area for further renewable energy development. However, the amount of water that is in storage in the basin greatly exceeds the amount of cumulative overdraft, even taking into account the potential for dramatically increased water demand, rendering the project's relatively small contribution to this cumulative impact less than cumulatively considerable.

4. The cumulative effects may indirectly impact the adjacent Palo Verde Mesa Groundwater Basin by inducing underflow from the Colorado River. To mitigate the project's contribution to impacts to the Colorado River, staff recommends adoption of **SOIL&WATER-14** that would require the project owner to acquire entitlements or offsets to Lower Colorado River water. Staff has also proposed Condition of Certification **SOIL&WATER-17** which allows the project owner to refine estimates of the amount of induced Colorado River underflow through computer modeling analysis and adjust the required acquisition of entitlements or offsets to Lower Colorado River water accordingly.

5. The project owner proposes a dry-cooled facility that when fully operational would use 201 acre-feet a year (afy) of groundwater from onsite wells. Groundwater is the only available source of water. Pumped water would be used for various purposes, including domestic use by workers, dust suppression, and mirror washing. Water is the only feasible means of cleaning the mirrors, which must be clean to maintain efficiency. Process makeup water would be recycled to supplement groundwater supplies. Overall use of the water is efficient for this technology, requiring about 40 afy per 100 MW of capacity.

   The quality of the groundwater varies significantly throughout the CVGB, and varies with depth. In general, groundwater below the project site would not meet water quality standards for domestic supply without treatment, because of elevated levels of total dissolved solids (TDS) and high concentrations of fluoride, chloride, boron, and sulfate. Staff concludes that the Project complies with the state's water policy to feasibly use the least amount of the lowest-quality water available.

6. The PSEGS would generate wastewater that would include: reverse osmosis (RO) reject water, auxiliary equipment blowdown water and sanitary wastewater. The project proposes to use evaporation ponds to treat the RO reject water and auxiliary equipment blowdown water; and sanitary leachfields to treat the sanitary wastewater. Conditions of Certification **SOIL&WATER-6** and **SOIL&WATER-7** would ensure that the operation of the wastewater treatment systems are in accordance with regulatory requirements and minimize potential impacts to surface and groundwater quality. In addition, Condition of Certification **SOIL&WATER-18** would monitor existing groundwater quality to monitor compliance with the requirements set forth in **SOIL&WATER-6** and **SOIL&WATER-7.**

7. The project owner proposes to operate a non-transient, non-community water system during operation of the project. The project owner would be required to submit all requirements, specifications, certifications to permit and operate of a non-transient, non-community water system as per Condition of Certification **SOIL&WATER-19.** In addition, the project owner would be required to comply with groundwater production reporting requirements following Condition of Certification **SOIL&WATER-15.** Lastly, the project owner would be required to monitor and mitigate potential ground subsidence associated with groundwater production following Condition of Certification **SOIL&WATER-16.**

8. The project owner would be required to submit a project closure and non-operation plan prior to site operations to ensure that at the time of project closure, the site is restored to pre-project conditions as required by Condition of Certification **SOIL&WATER-13**.

PROPOSED CONDITIONS OF CERTIFICATION

Staff has proposed modifications to the **Soil & Water Resources** Conditions of Certification as shown below. (**Note:** Deleted text is in ~~strikethrough~~, new text is **<u>bold and underlined</u>**)

DRAINAGE EROSION AND SEDIMENTATION CONTROL PLAN (DESCP)

SOIL&WATER-1 Prior to site mobilization, the project owner shall obtain the Compliance Project Manager (CPM) approval of the Drainage Erosion and Sedimentation Control Plan (DESCP) for managing storm water during Project construction and operations as normally administered by the County of Riverside. The DESCP must ensure proper protection of water quality and soil resources, demonstrate no increase in off-site flooding potential, include provisions for sediment and storm water retention from both the power block, solar fields and transmission right of way to meet any Riverside County requirements, address exposed soil treatments in the solar fields for both road and non-road surfaces, and identify all monitoring and maintenance activities. The plan must also cover all linear project features such as offsite transmission mains. The DESCP shall contain, at minimum, the elements presented below that outline site management activities and erosion and sediment-control Best Management Practices (BMP) to be implemented during site mobilization, excavation, construction, and post construction (operating) activities.

A. Vicinity Map – A map(s), at a minimum scale 1 inch to 500 feet, shall be provided indicating the location of all Project elements (construction sites, laydown area, pipelines) with depictions of all significant geographic features including swales, storm drains, and sensitive areas.

B. Site Delineation – All areas subject to soil disturbance for the proposed Project (Project phases, laydown area, all linear facilities, landscaping areas, and any other Project elements) shall be delineated showing boundary lines of all construction areas and the location of all existing and proposed structures, pipelines, roads, and drainage facilities.

C. Watercourses and Critical Areas – The DESCP shall show the location of all nearby watercourses including swales, storm drains, and ~~drainage ditches~~ **desert washes**. It shall indicate the proximity of those features to the proposed Project construction, laydown, and landscape areas and all transmission and pipeline construction corridors.

1~~a.~~ The DESCP shall describe how the project will avoid or minimize impacts to Palen-McCoy Valley sand corridor,

2~~b.~~ All proposed linear features (with the exception of Power Pylons) shall be constructed flush with the surrounding ground surface and without ground level obstructions.

3~~c~~. Earthwork and temporary construction related activities shall be conducted such that off-site resources are protected from impacts due to redirection of flood flows around and through the site. Construction activities shall proceed in a manner so as to minimize exposure of facilities to construction period flooding. Temporary diversion channels shall be adequately designed for flood conveyance capable of protecting the construction site while not contributing to onsite or offsite erosion.

D. **Drainage Map** – The DESCP shall provide a topographic site map(s), at a minimum scale of 1 inch to 200 feet, showing existing, interim, and proposed drainage swales and drainage systems and drainage-area boundaries. On the map, spot elevations are required where relatively flat conditions exist. The spot elevations and contours shall be extended off-site for a minimum distance of 100 feet.

E. **Drainage of Project Site Narrative** – The DESCP shall include a narrative of the drainage measures necessary to protect the site and potentially affected soil and water resources within the drainage downstream of the site. The narrative shall include the summary pages from the hydraulic analysis prepared by a professional engineer and erosion control specialist. The narrative shall state the watershed size(s) in acres that was used in the calculation of drainage features.

F. **Clearing and Grading Plans** – The DESCP shall provide a delineation of all areas to be cleared of vegetation and areas to be preserved. The plan shall provide elevations, slopes, locations, and extent of all proposed grading as shown by contours, cross sections, or other means. The locations of any disposal areas, fills, or other special features shall also be shown. Existing and proposed topography shall be illustrated by tying in proposed contours with existing topography.

G. **Clearing and Grading Narrative** – The DESCP shall include a table with the estimated quantities of material excavated or filled for the site and all Project elements (Project site, laydown area, transmission and pipeline corridors, roadways, and bridges) whether such excavation or fill is temporary or permanent, and the amount of such material to be imported or exported.

H. **Soil Wind and Water Erosion Control –** The plan shall address exposed soil treatments to be used during construction and operation of the proposed Project for both road and non-road surfaces including specifically identifying all chemical based dust palliatives, soil bonding, and weighting agents appropriate for use at the proposed Project site that would not cause adverse effects to vegetation. BMPs shall include measures designed to prevent wind and water erosion including application of chemical dust palliatives after rough grading to limit water use. All dust palliatives, soil binders, and weighting agents shall be approved by the CPM prior to use.

I. **Best Management Practices Plan –** The DESCP shall identify on the topographic site map(s) the location of the site specific BMPs to be employed during each phase of construction (initial grading, Project element excavation and construction, and final grading/stabilization). BMPs shall include measures designed to control dust, stabilize construction access roads and entrances, and control storm water runoff and sediment transport.

J. **Best Management Practices Narrative –** The DESCP shall show the location (as identified in (I) above), timing, and maintenance schedule of all erosion- and sediment-control BMPs to be used prior to initial grading, during all Project element (site, pipelines) excavations and construction, final grading/stabilization, and operation. Separate BMP implementation schedules shall be provided for each Project element for each phase of construction. The maintenance schedule shall include post-construction maintenance of structural-control BMPs, or a statement provided about when such information would be available.

K. **Project Schedule –** The DESCP shall identify on the topographic site map the location of the site-specific BMPs to be employed during each phase of construction (initial grading, Project element construction, and final grading/stabilization). Separate BMP implementation schedules shall be provided for each Project element for each phase of construction.

L. **Erosion Control Drawings –** The erosion-control drawings and narrative shall be designed, stamped and sealed by a professional engineer or erosion control specialist.

M. **Agency Comments –** The DESCP shall include copies of recommendations, conditions, and provisions from the County of Riverside, California Department of Fish and Game (CDFG), and Colorado River Basin Regional Water Quality Control Board (CRBRWQCB).

N. **Monitoring Plan:** Monitoring activities shall include routine measurement of the volume of accumulated sediment in the onsite drainage ditches, and storm water diversions. ~~The monitoring plan shall be part of the Channel Monitoring and Maintenance Plan, **SOIL&WATER-12.**~~

Verification: No later than 30 days prior to start of site mobilization, the project owner shall submit a copy of the final DESCP to the County of Riverside, the CRBRWQCB, and the CPM for review and comment and to the County of Riverside and the CRBRWQCB if required. The CPM shall consider comments if received by the county and CRBRWQCB before approval of the DESCP.

The DESCP shall be consistent with the grading and drainage plan and relevant portions of the DESCP shall clearly show approval by the chief building official. The DESCP shall be a separate plan from the SWPPP developed in conjunction with any National Pollutant Discharge Elimination System (NPDES) permit for Construction Activity. The project owner shall provide in the monthly compliance report with a narrative on the effectiveness of the drainage, erosion, and sediment-control measures and the results of monitoring and maintenance activities. Once operational, the project owner shall update and maintain the DESCP for the life of the Project and shall provide in the annual compliance report information on the results of monitoring and maintenance activities.

PROJECT GROUNDWATER WELLS, PRE-WELL INSTALLATION

SOIL&WATER-2 The project owner proposes to construct and operate up to ten (10) onsite groundwater water supply wells that produce water from the CVGB. The project owner shall ensure that the wells are completed in accordance with all applicable state and local water well construction permits and requirements. Prior to initiation of well construction activities, the project owner shall submit for review and comment a well construction packet to the County of Riverside and fees normally required for the county's well permit, with copies to the CPM. The Project shall not construct a well or extract and use groundwater until approval has been issued by the County and the CPM to construct and operate the well. Wells permitted and installed as part of pre-construction field investigations that subsequently are planned for use as project water supply wells require CPM approval prior to their use to supply water to the project.

Post-Well Installation. The project owner shall provide documentation as required under County permit conditions to the CPM that the well has been properly completed. In accordance with California's Water Code section 13754, the driller of the well shall submit to the DWR a Well Completion Report for each well installed. The project owner shall ensure the Well Completion reports are submitted. The project owner shall ensure compliance with all county water well standards and the County requirements for the life of the wells, and shall provide the CPM with two (2) copies each of all monitoring or other reports required for compliance with the County of Riverside water well standards and operation requirements, as well as any changes made to the operation of the well.

<u>Verification:</u> The project owner shall do all of the following:

a. No later than 60 days prior to the construction of the onsite groundwater production wells, the project owner shall submit to the CPM a copy of the water well construction packet submitted to the County of Riverside.

b. No later than 30 days prior to the construction of the onsite groundwater production wells, the project owner shall submit a copy of written concurrence received from the County of Riverside that the proposed well construction activities comply with all county well requirements and meet the requirements established by the county's water well permit program. The CPM will provide approval to the project owner of the well location and operation within 10 days of receipt of the County of Riverside's concurrence with the proposed well construction activities.

c. No later than 60 days after installation of each well at the Project site, the project owner shall ensure that the well driller submits a Well Completion Report to the DWR with a copy provided to the CPM. The project owner shall submit to the CPM together with the Well Completion Report a copy of well drilling logs, water quality analyses, and any inspection reports. Additionally no later than 60 days after installation of each well (including closure of any associated mud pits) the project owner shall submit documentation to the CPM and the CRBWQCB that well drilling activities were conducted in compliance with Title 23, California Code of Regulations, Chapter 15, Discharges of Hazardous Wastes to Land, (23 CCR, sections 2510 et seq.) and that any onsite drilling sumps used for Project drilling activities were removed in compliance with 23 CCR section 2511(c).

d. During well construction and for the operational life of the well, the project owner shall submit two copies each to the CPM of any proposed well construction or operation changes.

CONSTRUCTION AND OPERATION WATER USE

SOIL&WATER-3 The proposed Project's use of groundwater during construction shall not exceed ~~1,917~~ <u>**400**</u> afy (total of ~~5,750~~ <u>**1,130**</u> af during the ~~39~~ **34** months) during construction and ~~300~~ <u>**201**</u> afy during operation. Water quality used for project construction and operation shall be reported in accordance with Condition of Certification **SOIL&WATER-18** to ensure compliance with this condition.

Prior to the use of groundwater for construction, the project owner shall install and maintain metering devices as part of the water supply and distribution system to document Project water use and to monitor and record in gallons per day the total volume(s) of water supplied to the Project from this water source. The metering devices shall be operational for the life of the Project.

<u>**Verification:**</u> At least 60 days prior to the start of construction of the proposed Project, the project owner shall submit to the CPM a copy of evidence that metering devices have been installed and are operational.

Beginning six months after the start of construction, the project owner shall prepare a semi-annual summary of amount of water used for construction purposes. The summary shall include the monthly range and monthly average of daily water usage in gallons per day.

The project owner shall prepare an annual summary, which shall include daily usage, monthly range and monthly average of daily water usage in gallons per day, and total water used on a monthly and annual basis in acre-feet. For years subsequent to the initial year of operation, the annual summary shall also include the yearly range and yearly average water use by source. For calculating the total water use, the term "year" shall correspond to the date established for the annual compliance report submittal.

GROUNDWATER LEVEL MONITORING, MITIGATION, AND REPORTING

SOIL&WATER-4 The project owner shall submit a Groundwater Level Monitoring, Mitigation, and Reporting Plan to the CPM for review and approval in advance of construction activities and prior to the operation of onsite groundwater supply wells. The Groundwater Level Monitoring, Mitigation, and Reporting Plan shall provide detailed methodology for monitoring background and site groundwater levels. Monitoring shall include pre-construction, construction, and Project operation water use. The plan shall establish pre-construction and Project related groundwater level and water quality trends that can be quantitatively compared against observed and simulated trends near the Project pumping wells and near potentially impacted existing wells.

A. Prior to Project Construction

1. A well reconnaissance shall be conducted to investigate and document the condition of existing water supply wells located within 3 miles of the project site, provided that access is granted by the well owners. The reconnaissance shall include sending notices by registered mail to all property owners within a 3 mile radius of the project area.

2. Monitor to establish preconstruction conditions. The monitoring plan and network of monitoring wells shall make use of existing wells in the basin that would satisfy the requirements for the monitoring program. The monitoring network shall be defined by the groundwater model developed for the AFC as the area predicted to show a water level change of 1 feet or more at the end of construction and at the end of operation and any monitoring wells that are installed to comply with Waste Discharge Requirements issued by the Energy Commission for the evaporation ponds and land treatment unit associated with the Project. The projected area of groundwater drawdown shall be refined on an annual basis during project construction and every three (3) years during project operations using the data acquired as part of Condition of Certification **SOIL&WATER-4** as well as the numerical groundwater model developed as part of the AFC and subsequent Data Responses by the applicant. If the area predicted to show a water level change of 1 feet increases, the project owner will be required to submit a revised monitoring plan with additional monitoring wells (if required).

3. Identified additional wells shall be located outside of this area to serve as background monitoring wells. Abandoned wells, or wells no longer in use, that are accessible and provide reliable water level data within the potentially impacted area shall also be included as part of the monitoring network. A site reconnaissance shall be performed to identify wells that could be accessible for monitoring. As access to these wells is available, historic water level, water quality, well construction and well performance information shall be obtained for both pumping and non-pumping conditions.

4. As access allows, measure groundwater levels from the off-site and on-site wells within the network and background wells to provide initial groundwater levels for pre-project trend analysis.

5. Construct water level maps within the CVGB within 5 miles of the site from the groundwater data collected prior to construction. Update trend plots and statistical analyses, as data is available.

B. During Construction:

1. Collect water levels from wells within the monitoring network and flows from seeps and or springs on a quarterly basis throughout the construction period and at the end of the construction period. Perform statistical trend analysis for water levels. Assess the significance of an apparent trend and estimate the magnitude of that trend.

C. During Operation:

1. On a quarterly basis for the first year of operation and semi-annually thereafter for the following four years, collect water level measurements from any wells identified in the groundwater monitoring program to evaluate operational influence from the Project. Quarterly operational parameters (i.e., pumping rate) of the water supply wells shall be monitored. Additionally, quarterly groundwater-use in the CVGB shall be estimated based on available data.

2. On an annual basis, perform statistical trend analysis for water levels data and comparison to predicted water level declines due to project pumping. Analysis of the significance of an apparent trend shall be determined and the magnitude of that trend estimated. Based on the results of the statistical trend analyses and comparison to predicted water level declines due to Project pumping, the project owner shall determine the area where the Project pumping has induced a drawdown in the water supply at a level of 5 feet or more below the baseline trend.

3. If water levels have been lowered more than 5 feet below pre-site operational trends, and monitoring data provided by the project owner show these water level changes are different from background trends and are caused by Project pumping, then the project owner shall provide mitigation to the impacted well owner(s). Mitigation shall be provided to the impacted well owners that experience 5 feet or more of Project-induced drawdown if the CPM's inspection of the well monitoring data confirms changes to water levels and water level trends relative to measured pre-project water levels, and the well (private owners well in question) yield or performance has been significantly affected by Project pumping. The type and extent of mitigation shall be determined by the amount of water level decline induced by the Project, the type of impact, and site specific well construction and water use characteristics. If an impact is determined

to be caused by drawdown from more than one source, the level of mitigation provided shall be proportional to the amount of drawdown induced by the Project relative to other sources. In order to be eligible, a well owner must provide documentation of the well location and construction, including pump intake depth, and that the well was constructed and usable before Project pumping was initiated. The mitigation of impacts shall be determined as follows:

a. If Project pumping has lowered water levels by 5 feet or more and increased pumping lifts, increased energy costs shall be calculated. Payment or reimbursement for the increased costs shall be provided at the option of the affected well owner on an annual basis. In the absence of specific electrical use data supplied by the well owner, the project owner shall use **SOIL&WATER-5** to calculate increased energy costs.

b. If groundwater monitoring data indicate Project pumping has lowered water levels below the top of the well screen, and the well yield is shown to have decreased by 10% or more of the pre-Project average seasonal yield, compensation shall be provided for the diagnosis and maintenance to treat and remove encrustation from the well screen. Reimbursement shall be provided at an amount equal to the customary local cost of performing the necessary diagnosis and maintenance for well screen encrustation. Should the well yield reductions be recurring, the project owner shall provide payment or reimbursement for periodic maintenance throughout the life of the Project. If with treatment the well yield is incapable of meeting 110% of the well owner’s maximum daily demand, dry season demand, or annual demand the well owner should be compensated by reimbursement or well replacement as described under Condition 3.c.

c. If Project pumping has lowered water levels to significantly impact well yield so that it can no longer meet its intended purpose, causes the well to go dry, or cause casing collapse, payment or reimbursement of an amount equal to the cost of deepening or replacing the well shall be provided to accommodate these effects. Payment or reimbursement shall be at an amount equal to the customary local cost of deepening the existing well or constructing a new well of comparable design and yield (only deeper).. The demand for water, which determines the required well yield, shall be determined on a per well basis using well owner interviews and field verification of property conditions and water requirements compiled as part of the pre-project well reconnaissance. Well yield shall be considered significantly impacted if it is incapable of meeting 110% of the well owner’s maximum daily demand, dry-season demand, or annual demand – assuming the pre-project well yield documented by the initial well reconnaissance met or exceeded these yield levels.

d. The project owner shall notify any owners of the impacted wells within one month of the CPM approval of the compensation analysis for increased energy costs.

e. Pump lowering – In the event that groundwater is lowered as a result of Project pumping to an extent where pumps are exposed but well screens remain submerged the pumps shall be lowered to maintain production in the well. The Project shall reimburse the impacted well owner for the costs associated with lowering pumps.

f. Deepening of wells – If the groundwater is lowered enough as a result of Project pumping that well screens and/or pump intakes are exposed, and pump lowering is not an option, such affected wells shall be deepened or new wells constructed. The project owner shall reimburse the impacted well owner for all costs associated with deepening existing wells or constructing new wells shall be borne by the project owner.

4. After the first five-year operational and monitoring period the CPM shall evaluate the data and determine if the monitoring program for water level measurements should be revised or eliminated. Revision or elimination of any monitoring program elements shall be based on the consistency of the data collected. The determination of whether the monitoring program should be revised or eliminated shall be made by the CPM.

5. If mitigation includes monetary compensation, the project owner shall provide documentation to the CPM that compensation payments have been made by March 31 of each year of Project operation or, if lump-sum payments are made, payment is made by March 31 following the first year of operation only. Within 30 days after compensation is paid, the project owner shall submit to the CPM a compliance report describing compensation for increased energy costs necessary to comply with the provisions of this condition.

6. At the end of every subsequent five-year monitoring period, the collected data shall be evaluated by the CPM and they shall determine if the sampling frequency should be revised or eliminated.

7. During the life of the Project, the project owner shall provide to the CPM all monitoring reports, complaints, studies and other relevant data within 10 days of being received by the project owner.

Verification: The project owner shall do all of the following:

At least 60 days prior to operation of the site groundwater supply wells, the project owner shall submit to the CPM, a comprehensive report presenting all the data and information required in item A above. The CPM will provide comments to the plan 15 days following submittal, and the final plan shall be approved 15 days prior to operation of the site groundwater supply wells. The project owner shall submit to the CPM all calculations and assumptions made in development of the report data and interpretations.

During Project construction, the project owner shall submit to the CPM quarterly reports presenting all the data and information required in item B above. The quarterly reports shall be provided 30 days following the end of the quarter. The project owner shall also submit to the CPM all calculations and assumptions made in development of the report data and interpretations.

No later than March 31 of each year of construction or 60 days prior to Project operation, the project owner shall provide to the CPM for review and approval, documentation showing that any mitigation to private well owners during Project construction was satisfied, based on the requirements of the property owner as determined by the CPM.

During Project operation, the project owner shall submit to the CPM, applicable quarterly, semi-annual and annual reports presenting all the data and information required in item C above. Quarterly reports shall be submitted to the CPM 30 days following the end of the quarter. The fourth quarter report shall serve as the annual report and shall be provided on January 31 in the following year.

The project owner shall submit to the CPM all calculations and assumptions made in development of report data and interpretations, calculations, and assumptions used in development of any reports.

After the first five year operational and monitoring period, the project owner shall submit a 5 year monitoring report to the CPM that includes all monitoring data collected and a summary of the findings. The CPM will determine if the water level measurements and water quality sampling frequencies should be revised or eliminated.

COMPENSATION FOR WELL IMPACTS

SOIL&WATER-5 Where it is determined that the project owner shall reimburse a private well owner for increased energy costs identified as a result of analysis performed in Condition of Certification **SOIL&WATER-4,** the project owner shall calculate the compensation owed to any owner of an impacted well as described below.

<u>Increased cost for energy</u>	=	change in lift/total system head x total energy consumption x costs/unit of energy

Where:

change in lift (ft)	=	calculated change in water level in the well resulting from project
total system head (ft)	=	elevation head + discharge pressure head

elevation head (ft)	=	difference in elevation between wellhead discharge pressure gauge and water level in well during pumping.
discharge pressure head (ft)	=	pressure at wellhead discharge gauge (psi) X 2.31

The project owner shall submit to the CPM for review and approval the documentation showing which well owners must be compensated for increased energy costs and that the proposed amount is sufficient compensation to comply with the provisions of this condition.

- Any reimbursements (either lump sum or annual) to impacted well owners shall be only to those well owners whose wells were in service within six months of the Commission decision and within a 5-mile radius of the project site.
- The project owner shall notify all owners of the impacted wells within one month of the CPM approval of the compensation analysis for increase energy costs.
- Compensation shall be provided on either a one-time lump-sum basis, or on an annual basis, as described below.

Annual Compensation: Compensation provided on an annual basis shall be calculated prospectively for each year by estimating energy costs that will be incurred to provide the additional lift required as a result of the project. With the permission of the impacted well owner, the project owner shall provide energy meters for each well or well field affected by the project. The impacted well owner to receive compensation must provide documentation of energy consumption in the form of meter readings or other verification of fuel consumption. For each year after the first year of operation, the project owner shall include an adjustment for any deviations between projected and actual energy costs for the previous calendar year.

One-Time Lump-Sum Compensation: Compensation provided on a one-time lump-sum basis shall be based on a well-interference analysis, assuming the maximum project-pumping rate of 300 afy. Compensation associated with increased pumping lift for the life of the project shall be estimated as a lump sum payment as follows:

- The current cost of energy to the affected party considering time of use or tiers of energy cost applicable to the party's billing of electricity from the utility providing electric service, or a reasonable equivalent if the party independently generates their electricity;
- An annual inflation factor for energy cost of 3%; and
- A net present value determination assuming a term of 30 years and a discount rate of 9%;

The project owner shall do all of the following:

1. No later than 30 days after CPM approval of the well drawdown analysis, the project owner shall submit to the CPM for review and approval all documentation and calculations describing necessary compensation for energy costs associated with additional lift requirements.

2. The project owner shall submit to the CPM all calculations, along with any letters signed by the well owners indicating agreement with the calculations, and the name and phone numbers of those well owners that do not agree with the calculations.

Compensation payments shall be made by March 31 of each year of project operation or, if lump-sum payment is selected, payment shall be made by March 31 of the first year of operation only. Within 30 days after compensation is paid, the project owner shall submit to the CPM a compliance report describing compensation for increased energy costs necessary to comply with the provisions of this condition.

WASTE DISCHARGE REQUIREMENTS

SOIL&WATER-6 The project owner shall comply with the requirements specified in Appendix B, C, and D. These requirements relate to discharges, or potential discharges, of waste that could affect the quality of waters of the state, and were developed in consultation with staff of the State Water Resources Control Board and/or the applicable California Regional Water Quality Control Board (hereafter "Water Boards"). It is the Commission's intent that these requirements be enforceable by both the Commission and the Water Boards. In furtherance of that objective, the Commission hereby delegates the enforcement of these requirements, and associated monitoring, inspection and annual fee collection authority, to the Water Boards. Accordingly, the Commission and the Water Board shall confer with each other and coordinate, as needed, in the enforcement of the requirements. The project owner shall pay the annual waste discharge permit fee associated with this facility to the Water Boards. In addition, the Water Boards may "prescribe" these requirements as waste discharge requirements pursuant to Water Code Section 13263 solely for the purposes of enforcement, monitoring, inspection, and the assessment of annual fees, consistent with Public Resources Code Section 25531, subdivision (c).

<u>**Verification:**</u> The Project owner shall follow the groundwater quality monitoring requirements as provided in **SOIL&WATER-18** by providing Groundwater Quality Monitoring and Reporting Plan 90 days prior to operation of water supply wells for construction activities. The plan shall provide methods and procedures for monitoring background water quality, and site groundwater quality related to operation of the waste management units. Well locations, groundwater sampling procedures and analytical methods shall be provided consistent with requirements stipulated in the Waste Discharge Requirements provided in Appendix B, C and D.

No later than 60 days prior to any wastewater discharge or use of land treatment units, the project owner shall provide documentation to the CPM, with copies to the CRBRWQCB, demonstrating compliance with the WDRs established in Appendices B, C, and D. Any changes to the design, construction, or operation of the evaporation basins, treatment units, or storm water system shall be requested in writing to the CPM, with copies to the CRBRWQCB, and approved by the CPM, in consultation with the CRBRWQCB, prior to initiation of any ~~PSPP Soil and Water Opening Testimony Page 5~~ changes. The project owner shall provide to the CPM, with copies to the CRBRWQCB, all monitoring reports required by the WDRs, and fully explain any violations, exceedances, enforcement actions, or corrective actions related to construction or operation of the evaporation basins or treatment units.

SEPTIC SYSTEM AND LEACH FIELD REQUIREMENTS

SOIL&WATER-7 The project owner shall comply with the requirements of the County of Riverside Ordinance Code Title 8, Chapter 8.124 and the California Plumbing Code (California Code of Regulations Title 24, Part 5) regarding sanitary waste disposal facilities such as septic systems and leach fields. The septic system and leach fields shall be designed, operated, and maintained in a manner that ensures no deleterious impact to groundwater or surface water. Compliance shall include an engineering report on the septic system and leach field design, operation, maintenance, and loading impact to groundwater.

Verification: The project owner shall submit all necessary information and the appropriate fee to the County of Riverside and the CRBRWQCB to ensure that the project has complied with county and state sanitary waste disposal facilities requirements. Written assessments prepared by the County of Riverside and the CRBRWQCB regarding the project's compliance with these requirements must be submitted to the CPM for review and approval 30 days prior to the start of power plant operation.

~~REVISED PROJECT DRAINAGE REPORT AND PLANS~~

SOIL&WATER-8: **DELETED** ~~The project owner shall provide a revised Drainage Report which includes the following additional information:~~

~~A. Sizing of the Center Channel which considers the potential failure of the earthen berm located along the Corn Spring Wash crossing under I-10.~~

~~B. Revised onsite hydrology calculations using CN values consistent with the Riverside County Hydrology Manual for graded areas.~~

~~C. Detailed analysis and documentation of onsite swales and drainage channels demonstrating adequate capacity to ensure overtopping will not occur. This is of special concern for collector channels which are located at the top of terraces where there is a large drop (20 feet ±) from the outside of the channel to the lower terrace. It shall be demonstrated that seepage from these channels will not compromise the adjacent slope to the lower terrace.~~

~~D. Detailed scour calculations to justify toe-down depths for all soil cement segments, drop structures, slope protection, and any other features where scour is an issue.~~

~~E. Revised onsite hydrology map showing peak discharge values at locations where the onsite drainage system discharges into the West, Center, or East channels, or directly offsite.~~

~~F. Hydraulic and scour analysis for proposed drainage modifications associated with the construction of linear features including culvert crossings, at-grade crossings, bank protection and other potential features.~~

~~G. Digital copies of all HEC-HMS and HEC-RAS analysis.~~

~~H. A specific discussion of how the proposed onsite drainage design will protect the facility from erosion and the possible failure of the facilities resulting in a release of HTF.~~

~~The project owner shall also provide the 30% Grading and Drainage Plans which include the design based on information provided in the revised Drainage Report outlined above.~~

~~**Verification:** The project owner shall submit a Revised Project Drainage Report with the 30% Grading and Drainage Plans to the CPM for their review and comments 30 days prior to construction activities. The project owner shall address comments provided by the CPM until approval of the report is issued. All comments and concepts presented in the approved Revised Project Drainage Report with the 30%Grading and Drainage Plans shall be included in the final Grading and Drainage Plans. The Revised Project Drainage Report and 30% Grading and Drainage Plans shall be approved by the CPM.~~

~~DETAILED FLO-2D ANALYSIS~~

SOIL&WATER-9: **DELETED** ~~The project owner shall provide a detailed hydraulic analysis utilizing FLO-2D which models pre- and post-development flood conditions for the 10-, 25- and 100-year storm events. The post-development model must include all proposed collector channels, end diffuser structures and berms. The methods and results of the analysis must be fully documented in a Technical Memorandum or in the revised Project Drainage Report required in **SOIL&WATER-8**. Graphical output must include depth and velocity mapping as well as mapping which graphically shows the changes in both of these parameters between the pre- and post development conditions. Color shading schemes used for the mapping must be consistent between all maps as well as clear and easily differentiated between designated intervals for hydraulic parameters. Intervals to be used in the mapping are as follows:~~

- ~~Flow Depth: at 0.20 ft intervals up to 1 ft, and 0.40 ft intervals thereafter.~~
- ~~Velocity: 0.5 ft/s intervals~~

~~A set of figures shall be provided at a scale of no less than 1 inch 200 feet which show the extent and depths of flows entering the North, South and West channels for the 100-year event. A figure at the same scale shall also be provided for depth, velocity and the relative change in these parameters at and downstream of the four end diffuser structures for the 10-, 25- and 100-year events. Digital input and output files associated with the FLO-2D analysis must be included with all submittals. The results of this analysis shall be used for design of the 30% project grading and drainage plans.~~

~~**Verification:** The project owner shall submit a detailed FLO-2D analysis to the CPM for review and comment in addition to the 30% Grading and Drainage Plans and revised Project Drainage Report required in **SOIL&WATER-8**. The project owner shall address comments provided by the CPM until approval of the analysis is issued.~~

~~DRAINAGE CHANNEL DESIGN~~

SOIL&WATER-10: **DELETED**~~All collector and conveyance channels shall be constructed consistent with Riverside County Flood Control and Water Conservation District (RCFCWCD) guidelines where applicable. Grade control structures shall be utilized where needed to meet channel velocity and Froude number requirements. Channels shall be sized along discreet sections based on the results of the detailed FLO-2D analysis described in **SOIL&WATER-9**. All grade control and drop structures shall have adequate toe-down to account for the design drop plus two additional feet to account for potential downcutting of the channel over time. Channel confluence design must be given special consideration, especially as the preliminary Grading and Drainage Plans show 90 degree angles of confluence at nearly all locations. The issues of confluence hydraulics and potential scour shall be specifically addressed in the revised Drainage Report.~~

~~Offsite flows shall discharge directly into collector channels following the natural drainage patterns.~~

~~The proposed collector channel design must be fully documented in the Grading and Drainage plans and must include the following information:~~

~~A. Detailed and accurate cut/fill lines demonstrating in plan view how the channel would tie into existing grade and the solar facility.~~

~~B. Channel cross-sections at 100-foot intervals showing the channel geometry, existing grade, proposed grade at the facility and how the channel would tie in at on both sides.~~

~~C. Detailed channel profiles showing existing and finished grades at channel flow line and left and right banks. All drop structures as well as the toe of soil cement profile must also be shown and fully annotated. The 100-year water surface elevation shall be provided on all profiles.~~

~~D. Typical sections and design details for all discreet channel sections, drop structures, channel confluences, flow dispersion structures and other relevant drainage features.~~

~~E. Details of all drainage modifications associated with the construction of linear features such as culverts, at-grade crossings, bank protection and other potential features.~~

~~F. Consistent nomenclature and stationing on all plans, sections, profiles and details.~~

~~**Verification:** The project owner shall prepare preliminary, 30% channel design drawings and submit two copies for the CPM review and comment. The preliminary design drawings shall be submitted at the same time as the **Revised Project Drainage Report** in **SOIL&WATER-8** and FLO 2D Analysis in **SOIL&WATER-9**. The project owner shall update and modify the design as necessary to obtain the CPM approval.~~

~~CHANNEL EROSION PROTECTION~~

SOIL&WATER-11: **DELETED**~~The project owner shall provide revised preliminary Grading and Drainage Plans which incorporate the items and information as listed below for the channels designated as North, West, South, Southeast and Central on the existing plans (AECOM 2010a).~~

A. ~~Soil cement bank protection must be provided such that the channels are protected from bank erosion and lateral headcutting. The extents of the proposed bank protection must be shown on the revised Grading and Drainage Plans. Typical sections for these channels must show the layout of the bank protection including thickness, width and toe-down location and depth consistent with the scour calculation provided in the revised Drainage Report.~~

B. ~~Soil cement bank protection shall be provided on both channel banks wherever 10-year channel flow velocity exceeds 5 ft/s. It shall be provided on the outer channel bank wherever offsite topography and a detailed FLO-2D analysis indicate surface flow would enter the collector channels.~~

C. ~~Soil cement bank protection shall be provided at all channel confluences of otherwise unlined channels where the result of the detailed hydraulic analysis presented in the revised Drainage Report indicate the increased potential for erosion due to adverse angles of confluence. Detailed plans for each confluence showing the extents of the soil cement based on specific hydraulic conditions shall be provided in the formal Grading and Drainage Plans.~~

D. ~~Other methods of channel stabilization, such as dumped riprap or gabions, will not be permitted. Bio-stabilization measures are not permitted.~~

E. ~~Earthen berms used on the outside of collector channels to guide flow to discreet points of discharge into a channel shall not be utilized in lieu of soil cement on the outside bank of collector channels. Offsite flows shall discharge directly into collector channels.~~

F. ~~Design and construction criteria for the use of soil cement on the site shall be prepared by the Owner/Developer's engineer in conjunction with the design methodology established by the Geotechnical Engineer of Record. The design and construction criteria shall be based on local and/or regional requirements and specifications. The design and construction criteria, the geotechnical design for the soil cement, the site specific specifications for the soil cement, the method of installation for the soil cement, and the local or regional standards being used for the design criteria shall be provided to the CPM for review and comment consistent with the verification requirements for this Condition of Certification. The slope requirements that are proposed for use (3:1 or 4:1), and the associated method of installation (i.e., 8 inch lift versus slope application) shall be fully documented for review and approval by the CPM prior to any field installation of soil cement.~~

G. ~~A soils report indicating the suitability of the Project soils for use in the production of soil cement to the Project specifications shall be submitted with the revised Grading and Drainage Plans.~~

H. ~~The bottom of engineered collector channels may be left earthen or fully lined at the discretion of the engineer. Fully lined channels will have higher allowable velocities and Froude numbers assuming hydraulic jumps are modeled and considered in the channel design.~~

I. ~~Modifications to the existing drainages to allow construction of and future access to linear facilities shall require stabilization of the channels in the vicinity of those modifications. Locations of disturbance to the existing drainages shall be stabilized consistent with sound engineering practice to eliminate future negative impacts upstream and downstream of the linear facility in the form of downcutting, erosion and headcutting. The use of "non-engineered" culvert crossings shall not be allowed. All structures to be utilized in existing drainages along linear facilities shall be documented in the project drainage report and reflected in the project improvement plans. Channel erosion mitigation measures along linear facilities shall be subject to all the requirements of this Condition of Certification where applicable.~~

~~**Verification:** The required information and criteria shall be incorporated into the Grading and Drainage Plans and with all subsequent submittals as required in **SOIL&WATER-8** and **SOIL&WATER-9**. The project owner shall address all comments by the CPM related to the channel erosion protection design through final plan approval.~~

~~CHANNEL MAINTENANCE PROGRAM~~

SOIL&WATER-12: **DELETED**~~The project owner shall develop and implement a Channel Maintenance Program that provides long-term guidance to implement routine channel maintenance projects and comply with conditions of certification in a feasible and environmentally sensitive manner. The Channel Maintenance Program will be a process and policy document prepared by the project owner, reviewed and approved by the CPM. The Channel Maintenance Program shall include the following:~~

~~A.~~ ~~**Purpose and Objectives** – Establishes the main goals of the Program, of indefinite length, to maintain the diversion channel to meet its original design to provide flood protection, support Project mitigation, protect wildlife habitat and movement/ migration, and maintain groundwater recharge.~~

~~B.~~ ~~**Application and Use** - The channel maintenance work area is defined as the Project engineered channel, typically extending to the top of bank, include access roads, and any adjacent property that the Project owns or holds an easement for access and maintenance. The Program shall include all channel maintenance as needed to protect the Project facilities and downstream property owners.~~

~~C.~~ ~~**Channel Maintenance Activities**~~

~~1.~~ ~~**Sediment Removal** - sediment is removed when it: (1) reduces the diversion channel effective flood capacity, to less than the design discharge, (2) prevents appurtenant hydraulic structures from functioning as intended, and (3) becomes a permanent, non-erodible barrier to instream flows.~~

~~2.~~ ~~**Vegetation Management** - manage vegetation in and adjacent to the diversion channel to maintain the biological functions and values proposed in the mitigation. Vegetation management shall include control of invasive or nonnative vegetation as prescribed in Condition of Certification **BIO-14**.~~

~~3.~~ ~~**Bank Protection and Grade Control Repairs** – Bank protection and grade control structure repairs involve any action by the project owner to repair eroding banks, incising toes, scoured channel beds, as well as preventative erosion protection. The project owner shall implement instream repairs when the problem: (1) causes or could cause significant damage to the Project; adjacent property, or the structural elements of the diversion channel; (2) is a public safety concern; (3) negatively affects groundwater recharge; or (4) negatively affects the mitigation vegetation, habitat, or species of concern.~~

~~4.~~ ~~**Routine Channel Maintenance** - trash removal and associated debris to maintain channel design capacity; repair and installation of fences, gates and signs; grading and other repairs to restore the original contour of access roads and levees (if applicable); and removal of flow obstructions at Project storm drain outfalls.~~

5. ~~**Channel Maintenance Program – Exclusions** including: emergency repair and CIP.~~

D. ~~**Related Programmatic Documentation** – the CPM will review and approve the Channel Maintenance Program programmatic documentation. Maintenance activities shall comply with the streambed alteration agreement provisions and requirements for channel maintenance activities consistent with California's endangered species protection regulations and other applicable regulations.~~

E. ~~**Channel Maintenance Process Overview**~~

1. ~~**Program Development and Documentation** – This documentation provides the permitting requirements for channel maintenance work in accordance with the conditions of certification for individual routine maintenance of the engineered channel without having to perform separate CEQA/NEPA review or obtain permits.~~

2. ~~**Maintenance Guidelines** - based on two concepts: (1) the maintenance standard and (2) the acceptable maintenance condition, and applies to sediment removal, vegetation management, trash and debris collection, blockage removal, fence repairs, and access road maintenance.~~

3. ~~**Implementation** – Sets Maintenance Guidelines for vegetation and sediment management. The Project's vegetation management activities are established in Condition of Certification **BIO-14**. Maintenance Guidelines for sediment removal provide information on the allowable depth of sediment for the engineered channel that would continue to provide design discharge protection.~~

4. ~~**Reporting** – the CPM requires the following reports to be submitted each year as part of the Annual Compliance Report:~~

   a. ~~Channel Maintenance Work Plan – Describes the planned "major" maintenance activities and extent of work to be accomplished; and~~

   b. ~~Channel Maintenance Program Annual Report – Specifies which maintenance activities were completed during the year including type of work, location, and measure of the activity (e.g. cubic yards of sediment removed).~~

   c. ~~A report describing "Lessons Learned" to evaluate the effectiveness of both resource protection and maintenance methods used throughout the year.~~

F. ~~**Resource Protection Policies** - establishes policies to ensure that resources would be protected to the fullest extent feasible during routine channel maintenance activities. Policies shall be developed to guide decision-making for channel maintenance activities. BMPs shall be developed to implement these policies.~~

~~**Verification:** At least 60 days prior to the start of any project-related site disturbance activities (excluding linear construction), the project owner shall coordinate with the CPM to develop the Channel Maintenance Program. The project owner shall submit two copies of the programmatic documentation, describing the proposed Channel Maintenance Program, to the CPM (for review and approval). The project owner shall provide written notification that they plan to adopt and implement the measures identified in the approved Channel Maintenance Program. The project owner shall:~~

- ~~Supervise the implementation of a Channel Maintenance Program in accordance with conditions of certification;~~
- ~~Ensure the Project Construction and Operation Managers receive training on the Channel Maintenance Program;~~
- ~~As part of the Project Annual Compliance Report to the CPM, submit a Channel Maintenance Program Annual Report specifying which maintenance activities were completed during the year including type of work, location, and measure of the activity (e.g. cubic yards of sediment removed).~~

CLOSURE ~~AND DECOMMISSIONING~~ PLAN

SOIL&WATER-13 The project owner shall prepare **both a Provisional Closure Plan and a Final Closure Plan** ~~a decommissioning plan~~ that will meet the requirements of the BLM. The project owner shall identify likely **closure** ~~decommissioning~~ scenarios and develop **facility closure** ~~specific decommissioning~~ plans **in accordance with COM-15 "Facility Closure Plans" of the General Conditions.** ~~for each scenario that will identify a~~ **A**ctions to be taken to avoid or mitigate long-term impacts related to water and wind erosion after **the facility's closure need to be identified.** ~~decommissioning.~~ Actions may include such measures as a **facility closure** ~~decommissioning~~ SWPPP, revegetation and restoration of disturbed areas, post-**closure** ~~decommissioning~~ maintenance, collection and disposal of project materials and chemicals, and access restrictions.

Verification: ~~At least 60 days prior to the start of site mobilization or alternate date as agreed to with the CPM, the project owner shall submit decommissioning plans~~ **One (1) year after initiating commercial operation, the project owner must submit a Provisional Closure Plan and cost estimate for permanent closure to the CPM for review and approval. Three (3) years prior to closing, the owner must submit a Final Closure Plan** to the CPM for review and approval. The project owner shall amend these documents as necessary, with approval from the CPM, should the **facility closure** ~~decommissioning~~ scenario change in the future.

MITIGATION OF IMPACTS TO THE PALO VERDE MESA GROUNDWATER BASIN

SOIL&WATER-14 To mitigate the impact from Project pumping, the Project owner shall identify and implement offset measures to mitigate the increase in discharge from surface water to groundwater that affects recharge in the Palo Verde Valley Groundwater Basin (USGS). The project owner shall implement **SOIL&WATER-17** to evaluate the change in recharge over the life of the project including any latency effects from Project pumping. The activities shall include the following water conservation projects: payment for irrigation improvements in Palo Verde Irrigation District, payment for irrigation improvements in Imperial Irrigation District, purchase of water rights within the Colorado River Basin that will be held in reserve, and/or BLM's Tamarisk Removal Program or other proposed mitigation activities acceptable to the CPM.

The activities proposed for mitigation shall be outlined in a Water Offset Plan that will be provided to the CPM for review and approval and which shall include the following at a minimum:

A. Identification of the water offsets as determined in **SOIL&WATER-17**;

B. Demonstration of the Project owner's ability to conduct the activity;

C. Whether any governmental approval of the identified offset will be needed, and if so, whether additional approval will require compliance with CEQA or NEPA;

D. Demonstration of how much water is provided by each of the offset measures;

E. An estimated schedule for completion of the activities;

F. Performance measures that would be used to evaluate the amount of water replaced by the proposed offset measure; and,

G. A Monitoring and Reporting Plan outlining the steps necessary and proposed frequency of reporting to show the activities are achieving the intended benefits of the water supply offsets;

Verification: The project Owner shall submit a Water Offset Plan to the CPM for review and approval thirty (30) days before the start of extraction of groundwater for construction or operation.

The Project owner shall implement the activities reviewed and approved in the Water Offset Plan in accordance with the agreed upon schedule in the Water Offset Plan. If agreement with the CPM on identification or implementation of offset activities cannot be achieved the Project owner shall immediately halt construction or operation until the agreed upon activities can be identified and implemented.

GROUNDWATER PRODUCTION REPORTING

SOIL&WATER-15 The Project is subject to the requirement of Water Code Sections 4999 et. seq. for reporting of groundwater production in excess of 25 acre-feet per year.

<u>Verification</u>: The project owner shall file an annual "Notice of Extraction and Diversion of Water" with the SWRCB in accordance with Water Code Sections 4999 et. seq. The project owner shall include a copy of the filing in the annual compliance report.

GROUND SUBSIDENCE MONITORING AND ACTION PLAN

SOIL&WATER-16 One monument monitoring station per production well or a minimum of three stations shall be constructed to measure potential inelastic subsidence that may alter surface characteristics of the Chuckwalla Valley near the proposed production wells. The project owner shall:

A. Prepare and submit a Subsidence Monitoring Plan (SMP). The plan shall include the following elements:

   1. Construction diagrams of the proposed monument monitoring station including size and description, planned depth, measuring points, and protection measures;

   2. Map depicting locations (minimum of three) of the planned monument monitoring stations;

   3. Monitoring program that includes monitoring frequency, thresholds of significance, reporting format.

B. Prepare quarterly reports commencing three (3) months following commencement of groundwater production during construction and operations.

   1. The reports shall include presentation and interpretation of the data collected including comparison to the thresholds developed in Item C.

C. Prepare a Mitigation Action Plan that details the following:

   1. Thresholds of significance for implementation of proposed action plan;

      a. Any subsidence that may occur will not be allowed to damage existing structures either on or off the site or alter the appearance or use of the structure;

      b. Any subsidence that may occur will not be allowed to alter the natural drainage patterns or permit the formation of playas or lakes;

      c. Any subsidence that violates (a) or (b) will result in the project owner investigating the need to immediately reduce/cease pumping until the cause is identified or subsidence caused by project pumping abates and the structures and/or drainage patterns are stabilized and corrected.

2. Action Plan that details proposed actions by the ~~applicant~~**project owner** in the event thresholds are achieved during the monitoring program.

   The ~~applicant~~**project owner** shall submit the Ground Subsidence Monitoring and Action Plan that is prepared by an Engineering Geologist registered in the State of California 30 days prior to the start of extraction of groundwater for construction or operation.

Verification: The project owner shall do all of the following:

1. At least 30 days prior to project construction, the project owner shall submit to the CPM, a comprehensive report presenting all the data and information required in item A above.

2. The project owner shall submit to the CPM all calculations and assumptions made in development of the SMP.

3. During Project construction and operations, the project owner shall submit to the CPM quarterly reports presenting all the data and information required in item B above.

4. The project owner shall submit to the CPM all calculations and assumptions made in development of the report data and interpretations.

5. After the first five years of the monitoring period, the project owner shall submit a 5-year monitoring report to the CPM that submits all monitoring data collected and provides a summary of the findings. The CPM will determine if the Ground Subsidence Monitoring and Action Plan frequencies should be revised or eliminated.

ESTIMATION OF SURFACE WATER IMPACTS

SOIL&WATER-17 To further assess the impacts from Project pumping, the Project owner shall estimate the increase in discharge from surface water to groundwater that affects recharge in the Palo Verde Valley Groundwater Basin (PVVGB)(USGS). This estimate may be used for determining the appropriate offset volume in accordance with **SOIL&WATER-14**. The Project owner shall do the following to provide an estimate for review and approval by the CPM:

1. The Project owner shall conduct a detailed analysis of the affect from Project pumping on at the end of the 30 year operational period the change in groundwater outflow from the Chuckwalla Valley Groundwater Basin to the Palo Verde Valley and how the change in outflow may affect recharge of surface water to the PVVGB from the Project's groundwater extraction activities. The detailed analysis shall include:

   a. The conceptual model developed in the AFC and the Staff Assessment, for the Chuckwalla Valley Groundwater Basin and the Palo Verde Valley, and any changes resultant from further analysis in support of numerical modeling;

b. The use of an appropriately constructed groundwater model 1.) for the eastern portion of the Chuckwalla Valley Groundwater Basin that describes the effect from Project pumping on the outflow of groundwater to the Palo Verde Valley, and 2.) an appropriately constructed groundwater model of the Palo Verde Valley, inclusive of the mesa and floodplain. The models shall be coupled as appropriate to determine the effect from Project pumping on the surface water recharge in the Palo Verde Valley. Each model shall be constructed in consideration of the following:

    i. Horizontal and vertical geometry information gained through on- and offsite investigations conducted as part of the hydrogeological field investigations for the AFC, and any subsequently documented investigation performed as part of the model development ;

    ii. Aquifer properties developed as part of the AFC and any subsequently documented investigations performed as part of the model development, and an assessment of aquifer properties available from other published sources. The properties used shall be representative of the available data; and

    iii. The modeling effort shall include a sensitivity analysis where in the most sensitive variables will be identified and varied within a reasonable range outside of the calibration value to provide an assessment of the range of potential impacts from the Project pumping on the recharge from the Palo Verde Valley Groundwater Basin.

c. Reporting of the results of the modeling effort

d. Estimation of the increased contribution of surface water discharge to groundwater and the change in recharge to the Palo Verde Valley Groundwater Basin attributable to Project groundwater pumping.

2. The analysis shall include the following elements:

    a. The change in groundwater flux to the regional aquifer from surface water sources attributable to Project pumping in afy for the life of the Project (30 years) until pre-project (within 95%) conditions are achieved;

    b. A sensitivity analysis that would provide a range in the potential changes in flux relative to variation in the key model variables within each model as a result of Project pumping for life of the Project until pre-project (within 95%) conditions are achieved;

3. The project owner shall present the results of the conceptual model, numerical model, transient runs and sensitivity analysis in a report for review and approval by the CPM. The report shall include all pertinent information regarding the development of the numerical models. The report shall include as discussion of the following as appropriate to each model:
    a. Introduction
    b. Previous Investigations
    c. Conceptual Model
    d. Numerical Model and Input Parameters
    e. Sensitivity Analysis
    f. Transient Modeling Runs
    g. Conclusions

Verification: ~~Within thirty (30)~~ **At least ninety (90)** days ~~following certification~~ **prior to initiation of groundwater pumping for grading operations** of the proposed Project, the project owner shall submit to the CPM for their review and approval a report detailing the results of the modeling effort. The report shall include the estimated amount of change in discharge from surface water to groundwater within the Palo Verde Valley due to Project pumping. This estimate shall be used for determining the appropriate volume of water for offset in accordance with **SOIL&WATER-14.**

GROUNDWATER QUALITY MONITORING AND REPORTING PLAN

SOIL&WATER-18 The project owner shall submit a Groundwater Quality Monitoring and Reporting Plan to the CPM for review and approval. The Groundwater Quality Monitoring and Reporting Plan shall provide a description of the methodology for monitoring background and site groundwater quality following the Waste Discharge Requirements of **SOIL&WATER-6**, to assess the effects from pumping on changes in the aquifer water chemistry, and to monitor potential impacts from operation of proposed septic leach fields, if required. The initial background water quality sampling shall be implemented during the background groundwater level monitoring events in accordance with **SOIL&WATER-4**. Prior to project construction, access to offsite wells shall be obtained and samples collected and monitoring wells shall be installed to evaluate background water quality in the shallow and deep regional aquifer in areas that will be affected by Project pumping. These data will be used to establish pre-construction water quality that can be quantitatively compared against data gathered during construction and operation to assess if project pumping or a release from the waste management units (See **SOIL&WATER-6**), or septic systems (if required) has adversely affected the water supply or sensitive receptors.

1. A Groundwater Quality Monitoring and Reporting Plan shall be submitted to the CPM 90 days prior to operation of the water supply wells for construction. The Plan shall include a scaled map showing the site and vicinity, existing well locations, and proposed monitoring locations (both existing wells and new monitoring wells proposed for construction). Additional monitoring wells that shall be installed include wells required in accordance with Condition of Certification **SOIL&WATER-6**, for the evaporation ponds and land treatment unit proposed for the project, and if required for the sanitary leachfield system. The map shall also include relevant natural and man-made features (existing and proposed as part of this project). The plan also shall provide: (1) well construction information and borehole lithology for each existing well proposed for use as a monitoring well; (2) description of proposed drilling and well installation methods; (3) proposed monitoring well design; and, (4) schedule for completion of the work.

2. A Well Monitoring Installation and Groundwater Quality Network Report shall be submitted to the CPM for review and approval in conjunction with Condition of Certification **SOIL&WATER-4** and 60 days prior to operation of the water supply wells.. The report shall include a scaled map showing the final monitoring well network. It shall document the drilling methods employed, provide individual well construction as-builds, borehole lithology recorded from the drill cuttings, well development, and well survey results. The well survey shall measure the location and elevation of the top of the well casing and reference point for all water level measurements, and shall include the coordinate system and datum for the survey measurements. Additionally, the report shall describe the water level monitoring equipment employed in the wells and document their deployment and use.

3. As part of the monitoring well network development, all newly constructed monitoring wells shall be constructed consistent with State and Riverside County specifications.

4. Prior to use of any groundwater for construction, all groundwater quality and groundwater level monitoring data shall be reported to the CPM in the Well Monitoring Installation and Groundwater Quality Network Report that is due in conjunction with the background water level monitoring report under **SOIL&WATER-4** and 60 days prior to construction. The report shall include the following:

    a. An assessment of pre-project groundwater levels, a summary of available climatic information (monthly average temperature and rainfall records from the nearest weather station), and a comparison and assessment of water level data relative to the assumptions and spatial trends simulated by the ~~applicant~~**project owner's** groundwater model.

b. An assessment of pre-project groundwater quality with groundwater samples analyzed for those constituents required under the Waste Discharge Requirements (Appendix B, C and D) and if not included total dissolved solids (TDS), chloride, nitrates, major cations and anions, oxygen-18 and deuterium isotopes, and soluble metals.

c. The data shall be tabulated and include the estimated range (minimum and maximum values), average, and median for each constituent analyzed. If a sufficient number of data points are available from the background sampling, the data shall also be analyzed using the Mann-Kendall test for trend at 90% confidence to assess whether pre-project water quality trends, if any, are statistically significant.

5. During project construction and during the first five years of project operations, the project owner shall semi-annually monitor the quality of groundwater and changes in groundwater elevation and submit data semiannually to the CPM one month following the end of the 1st and 3rd quarter and following the operation reporting requirement under **SOIL&WATER-4**. After five years of project operations, the frequency and scope of the monitoring program shall be reassessed by the CPM. The semi-annual report shall document water level monitoring methods, the water level data, water level plots, and a comparison between pre- and post-project start-up water level trends as itemized below. The report shall also include a summary of actual water use conditions, monthly climatic information (temperature and rainfall) from the nearest meteorological monitoring station, and a comparison and assessment of water level data relative to the assumptions and simulated spatial trends predicted by the ~~applicant~~**project owner's** groundwater model.

   a. Groundwater samples from all wells in the monitoring well network shall be analyzed and reported semi-annually for those constituents required in the Waste Discharge Requirements (Appendix B, C and D) and if not included TDS, chloride, nitrates, cations and anions, oxygen-18 and deuterium isotopes.

   b. For analysis purposes, pre-project water quality shall be defined by samples collected prior to project construction as specified above, and compliance data shall be defined by samples collected after the construction start date to determine the effects from Project pumping and after the installation and operation of the waste management units in compliance with the Waste Discharge Requirements (Appendix B, C and D) and the sanitary leachfields, if required.

   c. Trends in water quality data shall be analyzed using the Mann-Kendall test for trend at the 90% confidence. Trends in the compliance data shall be compared and contrasted to pre-project trends, if any.

d. The contrast between pre-project and compliance mean or median concentrations shall be compared using an Analysis of Variance (ANOVA) or other appropriate statistical method approved by the CRBRWQCB for evaluation of water quality impacts. A parametric ANOVA (for example, an F-test) can be conducted on the two data sets if the residuals between observed and expected values are normally distributed and have equal variance, or the data can be transformed to an approximately normal distribution. If the data cannot be represented by a normal distribution, then a nonparametric ANOVA shall be conducted (for example, the Kruskal-Wallis test). If a statistically significant difference is identified at 90% confidence between the two data sets, the monitoring data are inconsistent with random differences between the pre-project and baseline data indicating a significant water quality impact from project pumping may be occurring.

e. If compliance data to evaluate the effects from Project pumping or potential impacts from operation of sanitary leachfield indicate that the water supply quality has deteriorated in (exceeds pre-project constituent concentrations in TDS, sodium, chloride, or other constituents identified as part of the monitoring plan and applicable Water Quality Objectives are exceeded for the applicable beneficial uses of the water supply) adjacent water supply wells that can be shown to be adversely influenced by Project Pumping for three consecutive years, the Project owner shall provide well-head treatment or a new water supply to either meet or exceed pre-project water quality conditions to any impacted water supply wells.

Verification: The project owner shall complete the following:

At least 90 days prior to construction, a Groundwater Level and Quality Monitoring and Reporting Plan shall be submitted to the CPM for review and approval.

At least 60 days prior to construction, a Well Monitoring Installation and Groundwater Level Network Report shall be submitted to the CPM for review and approval.

At least 60 days prior to use of any groundwater for construction, all groundwater quality and groundwater level monitoring data shall be reported to the CPM.

On a semiannual basis water quality data shall be collected during construction and 5 years following initial operation. The results of the monitoring will be reported on a semiannual basis, one month following the end of the 1st and 3rd quarters.

NON-TRANSIENT, NON-COMMUNITY WATER SYSTEM

SOIL&WATER-19 The Project is subject to the requirement of Title 22, Article 3, Sections 64400.80 through 64445 for a non-transient, non-community water system (serving 25 people or more for more than six months). In addition, the system shall require periodic monitoring for various bacteriological, inorganic and organic constituents.

Verification: The project owner shall submit the equivalent County of Riverside requirements to operate a non-transient, non-community water system with the County of Riverside at least 60 days prior to commencement of operations at the site. In addition, the project owner shall submit to the CPM a monitoring and reporting plan for production wells operated as part of the domestic water supply system prior to plant operations. The plan shall include reporting requirements including monthly, quarterly and annual submissions.

The project owner shall designate a California Certified Water Treatment Plant Operator as well as the technical, managerial and financial requirements as prescribed by State law. The project owner shall supply updates on an annual basis of monitoring requirements, any required submittals equivalent to the County of Riverside requirements including annual renewal requirements.

STORM WATER DAMAGE MONITORING AND RESPONSE PLAN

SOIL&WATER-20 The project owner shall reduce impacts caused by large storms by ensuring heliostats and diversion channels withstand the 100-year storm event, establishing ongoing maintenance and inspection of storm water controls, and implementing a response plan to clean up damage and address ongoing issues.

The project owner shall ensure that the heliostats and diversion channels are designed and installed to withstand storm water scour that may occur as a result of a 100-year, 24-hour storm event. The project owner shall implement a fence inspection and repair program to repair fencing after major storm events. The analysis of the storm event and resulting heliostat stability will be provided within a Pylon Insertion Depth and Heliostat Stability Report to be completed by the project owner. This analysis will incorporate results from site-specific geotechnical stability testing, as well as hydrologic and hydraulic storm water modeling performed by the project owner. The modeling will be completed using methodology and assumptions approved by the CPM.

The project owner shall also develop a Storm Water Damage Monitoring and Response Plan to evaluate potential impacts from storm water, including damage to diversion channels, perimeter fencing, and heliostats that fail due to storm water flow or otherwise break and scatter mirror debris or other potential pollutants on to the ground surface.

The basis for determination of pylon embedment depths shall employ a step-by-step process as identified below and approved by the CPM:

A. **Determination of peak storm water flow within each sub-watershed from a 100-year event:**

- **Use of *Riverside County Flood Control and Water Conservation District Hydrology Manual (Riverside County Manual)* to specify hydrologic parameters to use in calculations; and**

- HEC -1 and Flo-2D models (or other approved models) will be developed to calculate storm flows from the mountain watersheds upstream of the project site, and flood flows at the project site, based upon hydrologic parameters from Riverside County.

B. Determination of potential total pylon scour depth:

- Potential channel erosion depths will be determined using the calculated design flows, as determined in A above, combined with Flo-2D to model onsite sediment transport.
- Potential local scour will be determined using the calculated design flows, as determined in A above, combined with the Federal Highway Administration (FHWA) equation for local bridge pier scour from the FHWA 2001 report, "Evaluating Scour at Bridges."

C. The results of the scour depth calculations and pylon stability testing will be used to determine the minimum necessary pylon embedment depth within the active channels. In the inactive portions of the alluvial fans that are not subject to channel erosion and local scour, the minimum pylon embedment depths will be based on the results of the pylon stability testing.

D. The results of the calculated peak storm water flows and channel erosion and heliostat scour analysis together with the recommended heliostat installation depths shall be submitted to the CPM for review and approval sixty (60) days before the start of heliostat installation.

The Storm Water Damage Monitoring and Response Plan shall be submitted to the CPM for review and approval and shall include the following:

- Detailed maps showing the installed location of all heliostats within each project phase;
- Description of the method of removing all soil spoils should any be generated;
- Each heliostat should be identified by a unique ID number marked to show initial ground surface at its base, and the depth of the pylon below ground;
- Minimum Depth Stability Threshold to be maintained of pylons to meet long-term stability for applicable wind, water (flowing and static), and debris loading effects;
- Above and below ground construction details of a typical installed heliostat;
- BMPs to be employed to minimize the potential impact of broken mirrors to soil resources;

- **Methods and response time of mirror cleanup and measures that may be used to mitigate further impact to soil resources from broken mirror fragments; and**
- **Monitoring, documenting, and restoring the adjacent offsite downstream property when impacted by sedimentation or broken mirror shards.**

A plan to monitor and inspect periodically, before first seasonal and after every storm event:

- **Security and Tortoise Exclusion Fence: Inspect for damage and buildup of sediment or debris**
- **Heliostats within drainages or subject to drainage overflow or flooding: Inspect for tilting, mirror damage, depth of scour compared to pylon depth below ground and the Minimum Depth Stability Threshold, collapse, and downstream transport.**
- **Drainage channels: Inspect for substantial migration or changes in depth, and transport of broken glass.**
- **Constructed diversion channels: Inspect for scour and structural integrity issues caused by erosion, and for sediment and debris buildup.**
- **Adjacent offsite downstream property: Inspect for changes in the surface texture and quality from sediment buildup, erosion, or broken glass.**

Short-Term Incident-Based Response:

- **Security and Tortoise Exclusion Fence: repair damage, and remove built-up sediment and debris.**
- **Heliostats: Remove broken glass, damaged structure, and damaged wiring from the ground, and for pylons no longer meeting the Minimum Depth Stability Threshold, either replace/reinforce or remove the mirrors to avoid exposure for broken glass.**
- **Drainage channels: no short-term response necessary unless changes indicate risk to facility structures.**
- **Constructed diversion channels: repair damage, maintain erosion control measures and remove built-up sediment and debris.**

Long-Term Design-Based Response:

- **Propose operation/BMP modifications to address ongoing issues. Include proposed changes to monitoring and response procedures, frequency, or standards.**
- **Replace/reinforce pylons no longer meeting the Minimum Depth Stability Threshold or remove the mirrors to avoid exposure for broken glass.**

- Propose design modifications to address ongoing issues. This may include construction of active storm water management diversion channels and/or detention ponds.

Inspection, short-term incident response, and long-term design based response may include activities both inside and outside of the project boundaries. For activities outside of the project boundaries the owner shall ensure all appropriate environmental review and approval has been completed before field activities begin.

Verification: At least sixty (60) days prior to installation of the first pylon, the project owner shall submit to the CPM a copy of the Pylon Insertion Depth and Heliostat Stability Report for review and approval prior to construction. At least sixty (60) days prior to commercial operation, the project owner shall submit to the CPM a copy of the Storm Water Damage Monitoring and Response Plan for review and approval prior to commercial operation. The project owner shall retain a copy of this plan onsite at the power plant at all times. The project owner shall prepare an annual summary of the number of heliostats failed due to damage, cause and extent of the damage, and cleanup and mitigation performed for each damaged heliostat. The annual summary shall also report on the effectiveness of the diversion channels against storms, including information on the damage and repair work or associated erosion control elements. The project owner shall submit proposed changes or revisions to the Storm Water Damage Monitoring and Response Plan to the CPM for review and approval.

SOIL AND WATER RESOURCES – APPENDIX B

Staff has proposed modifications to the **Soil & Water Resources – Appendix B** as shown below. (**Note:** Deleted text is in ~~strikethrough~~, new text is **<u>bold and underlined</u>**)

FACTS FOR WASTE DISCHARGE — Palen Solar ~~I~~<u>Holdings</u>, LLC, Owner/Operator, Palen Solar ~~Power Project~~ <u>Electric Generating System</u>, Riverside County

1. ~~Solar Millennium~~**<u>Palen Solar Holdings</u>**, LLC, (the Discharger) is proposing to construct, own and operate a concentrated solar power **<u>tower</u>** (CSP) electric generating facility **<u>and</u>** evaporation ponds ~~and a land treatment unit (LTU)~~ on land owned by the Bureau of Land Management (BLM). The solar power **<u>tower</u>** project is proposed by Palen Solar ~~I~~**<u>Holdings</u>**, LLC (~~PSI~~**PSH**) a ~~wholly~~ **<u>company jointly</u>** owned ~~subsidiary of Solar Millennium, LLC~~ **<u>by BrightSource Energy and Abengoa Solar, LLC</u>**. The project is located in the Chuckwalla Valley along the Interstate 10 corridor (I- 10), east of Desert Center and west of the City of Blythe. The facility is referred to as the Palen Solar ~~Power Project (PSPP)~~ **<u>Electric Generating System (PSEGS or Project)</u>**. A site map (**Soil and Water Resources Appendix B Figure 1**), as incorporated herein and made a part of these requirements for waste discharge (Waste Discharge Requirements, or WDRs). The address for~~, Solar Millennium, LLC 1625 Shattuck Ave. Ste 270, Berkeley, Ca 94709-1161~~ **<u>PSH is 1999 Harrison Street, Suite 2150, Oakland, CA 94612.</u>**

2. These WDRs regulate the Facility's ~~four~~ **<u>two</u>** evaporation ponds~~ and two LTUs~~. The evaporation ponds are designated as Class II Surface Impoundments Waste Management Units (WMU) and must meet the requirements of the California Code of Regulations (CCRs), Title 27, CCR §20200 et seq. The boundaries of the ~~Palen Solar Project~~ **<u>PSEGS</u>** are shown on (**Soil and Water Resources Appendix B Figure 2**), as incorporated herein and made a part of these WDRs.

3. The Discharger submitted ~~two~~ **<u>one</u>** Report~~s~~ of Waste Discharge (ROWD), ~~January 6, 2010 for the LTU and~~ **<u>on</u>** May 25, 2010 for the evaporation ponds **<u>for the PSEGS</u>**. ~~for the Palen Solar Project.~~

4. Definition of terms used in these WDRs:

   a. **Facility** – The entire parcel of property where the proposed ~~Palen Solar Project~~**<u>PSEGS</u>** industrial operation or related solar industrial activities are conducted.

   b. **Waste Management Units (WMUs)** – The area of land, or the portions of the Facility where wastes are discharged. The ~~LTU and the~~ evaporation ponds are WMUs.

c. **Discharger** – The term Discharger means any person who discharges waste that could affect the quality of the waters of the State, and includes any person who owns the land, WMU or who is responsible for the operation of a WMU. Specifically, the terms “discharger” or “dischargers” in these WDRs means ~~Palen Solar I, LLC~~**PSH**.

Facility Location

5. The ~~Project~~ **Facility** site is located approximately 0.5 mile north of I-10 and approximately 10 miles east of Desert Center, in an unincorporated area of eastern Riverside County, California (**Soil and Water Resources Appendix B Figure 1**). Desert Center (population 125) is located along I-10 approximately halfway between the cities of Indio and Blythe, California, and is approximately three miles east of the southeast end of Joshua Tree National Park. The area inside the Project’s security fence, the footprint within which all Project facilities will be located, will occupy approximately 2,970 acres of Federal land managed by the BLM.

Surrounding Land Use

6. The Project site lies on 2,970 acres of vacant undeveloped desert located approximately 0.5 mile north of I-10 and 12 miles east of the small rural community of Desert Center. The Project site is not located in a designated wilderness area; however, it is located near lands that are designated as wilderness lands or Areas of Critical Environmental Concern (ACEC) (NECO Maps 2-38 and 2-4). The nearest Federal wilderness areas are located in mountainous land to the northeast and south of the Project site and referred to as the Palen/McCoy and Chuckwalla Mountains, respectively. The Chuckwalla Mountains are also designated by BLM as a Desert Wildlife Management Areas (DWMA); the Chuckwalla DWMA is located less than one mile south of the site and south of I-10. The Palen Dry Lake and dunes, located to the northeast of the Project site, are designated as ACEC. The edge of designated desert tortoise critical habitat extends into approximately 180 acres of the southwestern portion of the Facility.

7. South of I-10 is undeveloped public and private desert land. Undeveloped and irrigated desert is located west of the site where several large parcels are actively farmed. The nearest residence is located approximately 25 feet north of the Project’s ROW boundary and approximately 1,000 feet from Unit #2. One other residence is located approximately 3,500 feet north of the Project boundary. No other residences are known to exist within the one-mile radius of the Project site.

8. The Project site is vegetated with desert scrub throughout and includes some sand dunes in the northeast. Several dirt roads and transmission lines cross the Project site, as well as four desert northeast-southwest trending washes. Based on information in Northern and Eastern Colorado Desert (NECO) Plan, the Project site has not been leased for grazing by BLM. The nearest grazing lands are the Ford Dry Lake grazing allotment approximately 10 miles east of the site and north of I-10.

9. The site is currently undeveloped and few off-highway vehicle tracks were observed. The site does not appear to be frequented as a recreational area. No portion of the Facility is known to be an active recreational area.

10. The NECO Plan does not identify any scenic resources in the Project Study Area. The County of Riverside has identified the I-10 corridor as eligible for county designation as a scenic corridor. The I-10 corridor between Palm Springs and Blythe is not designated by the State of California as a scenic corridor.

Facility Description

11. The ~~PSPP~~ **PSEGS** is comprised of two, nominally rated 250 MW power blocks. The performance of each power block will vary with solar radiation and ambient temperature levels. At optimal solar radiation and low air cooled condenser back pressure (low ambient temperatures), the steam turbine-generator can produce 272 MW gross. As ambient temperature increases, the cooling effectiveness of the air cooled condenser decreases, causing the back pressure on the steam turbine to rise and, correspondingly, lowering steam turbine output. Parasitic loads also vary in relation to ambient temperature, due to the increasing power requirement for the large air cooled condenser and cooling plant auxiliary equipment. At an ambient temperature of 96°F, the steam turbine generator will produce 264 MW and plant parasitic load will be approximately 29 MW providing a net-to-grid power block rating of approximately 235 MW. Conversely, on a cool winter day with optimal solar radiation, the steam turbine generator will produce 272 MW, plant parasitic load will be approximately 28 MW and the net-to-grid power block rating will be approximately 244 MW.

12. The Project proposes to use dry cooling condenser for power plant cooling. Water for cooling tower makeup, process water makeup, and other industrial uses such as mirror washing will be supplied ~~U~~**u**p to ten onsite wells. This source will also be used to supply water for employee use (e.g., drinking, showers, sinks, and toilets). Water received from the on-site wells will be pumped directly to a reverse osmosis (RO) treatment unit to meet the requirements of the California Department of Health Services for potable water supplies. Power cycle makeup, mirror washing water, and cooling of ancillary equipment will require on-site treatment for reduction of dissolved solids, and this treatment varies according to the quality required for each of these uses.

13. The power generation cycle will not produce cooling tower blow down because the plant will be dry cooled. A small auxiliary cooling tower will generate a small amount of blow down, which will be reused on-site. No off-site backup cooling water supply is planned at this time.

14. The main waste stream at the site consists of industrial wastewater generated in the various processes associated with power generation. Industrial wastewater is treated via a high pH reverse osmosis at each of the two Power Units. At each Unit, the treated water is recycled to the ~~1,~~0**8**00,000-gallon Service/Fire Water tank for reuse in the process. The concentrate from the RO system is discharged to lined evaporation ponds (~~two~~ **one** per Unit). The ~~PSPP~~**PSEGS** Facility therefore includes ~~four~~ **two** proposed evaporation ponds for waste storage and disposal. Sanitary wastewater generated at each Unit is disposed of via septic systems.

15. The project will include evaporation ponds for the evaporation of brine waste from the RO plant and other industrial wastes. There will be ~~four~~ **two** ponds, ~~four~~ **two** acres in size and, ~~two within each power block~~ **both located next to the common area** (**Soil and Water Resources Appendix B Figure 2**). The evaporation ponds will be designed in accordance with Colorado River Basin Regional Water Quality Control Board (Regional Board) requirements.

~~16. The Project will include two LTUs to treat soil contaminated with HTF. Based on the release history from the NextEra LLC Kramer Junction Facility, which is a parabolic trough solar power plant that employs HTF in the same fashion as proposed for the PSPP and which also has LTUs, the PSPP LTUs have been designed in accordance with CCR Title 27 requirements and to receive about 1,666 cubic yards of impacted soil on an annual basis. There are two LTUs proposed for the Project. Each will cover an area of approximately 800 feet by 220 feet (4 acres) in the southern portion of the Project site (**Figure 2**). The LTUs will use indigenous bacteria and amendments to the soil to bioremediate HTFaffected soils to levels acceptable for reuse on-site. Characterization of the hazardous characteristics of HTF-affected soil will be established by the Department of Toxic Substances Control (DTSC) prior to operation and remediation. Soils in excess of the criterion established by the DTSC will be removed from the site and transported to an appropriate treatment storage and disposal facility. Soil with HTF at concentrations below this criterion will be managed in the LTUs and remediated to acceptable levels for reuse as fill on-site.~~

~~17~~**16**. The estimated project life for the Project is 30 years. Personnel will staff the Project 24 hours per day/seven days per week. Even when the solar power plant is not operating, personnel will be present as necessary for maintenance, to prepare the Project for startup, and/or for site security.

~~18~~**17**. A sanitary septic system and on-site leach field will be used to dispose of sanitary wastewater within each power block.

Climate

~~19~~**18**. The Project is located in an arid desert climate; therefore, there are extreme daily temperature changes, low annual precipitation, strong seasonal winds and mostly clear skies. Evaporation rates are higher than precipitation rates. Based on 60 years of data from Blythe Airport, the mean maximum temperatures in June to September exceed 100°F. Winter months are more moderate with mean maximum temperatures of high 60's to low 70's °F and minimum temperatures in the low to mid 40's °F. Although there are no average minimal temperatures below freezing point (32°F), the temperature has historically dropped below freezing point between November and March.

~~20~~**19**. Average annual evaporation in the Facility area, based on published data at the Indio Fire Station 70 miles west of the Project site, is 105 inches, of which 87 percent of that evaporation occurs between March and October. Average annual precipitation in the Project area, based on the gauging station at Blythe Airport, is 3.55 inches, with August recording the highest monthly average of 0.63 inches and June recording the lowest monthly average of 0.02 inches. Per the National Oceanic and Atmospheric Administration (NOAA) Atlas 14 for the Southern California area, 3.51 inches of rainfall shall fall in the 100 year, 24 hour storm event.

~~21~~**20**. Winds in the Project area are generally south to southwest with a less frequent component of northerly winds (north through northwest). Calm conditions occur approximately 16.43% of the time, with the annual average wind speed being approximately 7.62 miles per hour (mph) (3.41 m/s).

Regional Topography and Drainage

~~22~~**21**. The Project ~~S~~**s**ite is located on the alluvial sediments of the Chuckwalla Valley, and is 2 to 3 miles northeast of the Chuckwalla Mountains and approximately two miles southwest of the Palen Mountains. Surface water in the Chuckwalla Valley drains from the surrounding mountains toward Palen or Ford Dry Lakes (playas), the topographic low points within the valley.

~~23~~**22**. Site topography slopes gently to the northeast at grades of 1.4 percent or less. The general storm water flow pattern is from the higher elevations in the Chuckwalla Mountains, located approximately 6 miles southwest of the site, to the lower elevations in Chuckwalla Valley to the northeast. The site is mostly flat, with elevation ranging on United States Geological Survey (USGS) topographical maps from a high of about 625 feet above sea level at the southwestern limits of the site to a low of about 425 feet above sea level along the eastern site boundary. Storm water from the Project site flows to the northeast across the site and then southeast to a dry lake bed (Ford Dry Lake), which also receives overland flow from the Palen Mountains and the area toward I-10.

~~24~~**23**. The major watercourse in the Project area is Corn Springs Wash, which drains approximately 31 square miles of the Chuckwalla Mountains and flows northeast toward the Project site. Storm water flows and discharge from springs in the Chuckwalla Mountains travel through Corn Springs Wash and adjacent unnamed washes northeastward before being cut off by I-10. Storm water flows are intercepted by dikes located south of I-10 and conveyed to three box culverts that cut beneath the roadway of I-10, south (upgradient) of the Project site. These structures were constructed during construction of I-10 and are dikes and culverts that re-concentrate the flows back to three discrete discharge points on the north side of I-10. From these discharge points, storm water flows continue across the Project site flowing northeast towards Palen Mountains.

~~25~~**24**. Impacts to the ephemeral washes within the Project site will be mitigated by rerouting the washes in two new channels around the east and west sides of the facility and one through the center of the site (between Units #1 and #2). The new channels will be designed to be wildlife friendly, and drainage downstream of the site maintained as close as practicable to the pre-existing conditions. Storm Water Pollution Prevention Plans (SWPPP) and a CEC mandated Drainage, Erosion, and Sediment Control Plan (DESCP) were provided in the August 2009 PSPP Application for Certification and contain Best Management Practices (BMPs), which will be implemented to avoid significant drainage/stormwater runoff and water quality impacts.

Flood Hazard

~~26~~**25**. According to FEMA, no flood insurance rate maps have been created for the Project site and adjacent areas. Reviews of flood zone maps generated by the Riverside County Flood Control District also did not identify any flood zone maps for this area of Riverside County.

Regional Geology

~~27~~**26**. The Facility is located in the northwestern Colorado Desert, in the alluvial-filled basin of the Palo Verde Mesa, which is part of the greater Colorado Desert Geomorphic Province. The basin is bound by the McCoy Mountains to the west, the Little Maria Mountains to the northwest, and the Big Maria Mountains to the northeast. This area has a generally low relief until near the surrounding mountains. In the region, the Palo Verde Valley is roughly equivalent to the recent historic floodplain of the Colorado River. Surficial deposits of late Miocene to Holocene age form most of the land surface in the area. Most of these deposits are composed of Quaternary Alluvium, underlain by the Pliocene Bouse Formation, which is in turn unconformably underlain by the Miocene Fanglomerate. These deposits are all underlain by bedrock consisting of metamorphic and igneous intrusive rocks of pre-Tertiary age, including Proterozoic schist and gneiss, Paleozoic sedimentary rocks, and Mesozoic sedimentary and metavolcanic rock sequences.

Site Specific Geology

~~28~~**27**. The Project is located in the alluvial-filled basin of the Chuckwalla Valley. Regionally, this valley formed as a structural depression or a pull-apart basin and is composed of two broad geologic units: consolidated rocks and unconsolidated alluvium (DWR 1963, 1979). The consolidated rocks consist of pre-Tertiary age igneous and metamorphic rocks, which form the basement complex, and in some locations, Tertiary-age volcanic rocks that overlie the basement complex. The consolidated rocks are nearly impermeable except for areas where fracturing or weathering has occurred. It is uncertain the extent that these rocks yield water to the alluvium. Some literature indicates that the fractured bedrock is in communication with the alluvium and there are wells that are completed in the bedrock that yield sufficient quantities of water. The flux of groundwater into and out of the bedrock is unknown.

Seismicity

~~29~~**28**. The Project site is located in seismically active Southern California, a region that has experienced numerous earthquakes in the past. A review of the Alquist Priolo (AP) Earthquake Fault Maps and the Riverside County AP Earthquake Hazard Zone Map indicate that there are no AP fault zones present within the Project boundaries (California Division of Mines and Geology 2000, California Geological Survey 2003, 2007). In addition, no active fault zones are present within one mile of the Project site; however, the site is approximately 2.5 miles southwest of an unnamed fault located at the southern end of the Palen Mountains. This fault has not been mapped by the USGS as a Quaternary (sufficiently active) fault, and is not listed by the EQFAULT program as a fault potentially affecting the site (Blake 2000).

~~30~~**29**. Regardless of whether there are faults across the site, because the Project is located in a seismically active area, all Project structures must be designed to comply with the California Building Code (CBC) and Universal Building Code (UBC) Zone 4 requirements. The CBC and UBC are considered to be standard safeguards against major structural failures and loss of life. The goals of the codes are to provide structures that will:

a. Resist minor earthquakes without damage;

b. Resist moderate earthquakes without structural damage but with some nonstructural damage; and

c. Resist major earthquakes without collapse but with some structural and nonstructural damage.

~~31~~**30**. The CBC and UBC base seismic design on minimum lateral seismic forces ("ground shaking"). The CBC and UBC requirements operate on the principle that providing appropriate foundations, among other aspects, helps to protect buildings from failure during earthquakes.

~~32~~**31**. The Project site is located in seismically active Southern California, a region that has experienced numerous earthquakes in the past. A review of the Alquist Priolo (AP) Earthquake Fault Maps and the Riverside County AP Earthquake Hazard Zone Map indicate that there are no AP fault zones present within the Project boundaries (California Division of Mines and Geology 2000, California Geological Survey 2003, 2007).

Ground Rupture

~~33~~**32**. The Project site is not located within a State of California Earthquake Fault Zone designated by the Alquist-Priolo Special Studies Zone Act of 1972 (formerly known as a Special Studies Zone), an area where the potential for fault rupture is considered probable (Riverside County, 2008). In addition, no Quaternary, Sufficiently Active, or Well Defined Faults are located under or near the Site. Based on this information and engineering judgment, earthquake induced ground rupture is not considered to be a significant hazard at the Site.

Slope Stability

~~34~~**33**. The **Project** ~~S~~**s**ite is not considered to be an area with the potential for permanent ground displacement due to earthquake-induced landslides because surface topography at and near the site is relatively flat (Riverside County, 2008). A review of the Riverside County General Plan, Safety Element, did indicate areas considered susceptible to earthquake induced landslides and rock falls in the McCoy Mountains; however, these areas are several miles from the Site and are not expected to impact the Project. Based on this information and engineering judgment, slope instability is not considered to be a significant hazard at the Site.

Erosion

~~35~~**34**. Erosion is the displacement of solids (soil, mud, rock, and other particles) by wind, water, or ice and by downward or down-slope movement in response to gravity. Due to generally flat terrain, the Project site is not prone to significant mass wasting (gravity-driven erosion and non-fluvial sediment transport) at present. The Riverside County General Plan, Safety Element (Riverside County, 2008), indicates the Site is in an area with moderate potential for wind erosion, the off-site linears are in areas with moderate to high potential for wind erosion. Soil characteristics at the Project site allow for the potential for wind and water erosion, and significant sediment transport currently occurs across the valley axial drainage that crosses the majority of the proposed plant site. As indicated above, these valley axial deposits are characterized by subdued bar and swale topography and ongoing deposition from sheet floods. Limited sand and aeolian erosion also occurs between depositional episodes.

~~36~~**35**. To address the management of sediment transport, erosion and sedimentation during operation, the project design will incorporate diversion berms, channels, and dispersion structures. The final design for these features will be developed during detailed design, and will include industry-standard calculations and modeling to reduce the potential for erosion or sedimentation, and to reduce the need for ongoing maintenance. Dirt roads and exposed surfaces will be periodically treated with dust palliatives as needed to reduce wind erosion. Construction and maintenance of the proposed drainage and sediment management system at the Site is expected to reduce water and wind erosion at and downstream of the Site to less than significant levels.

Liquefaction

~~37~~**36**. Liquefaction is a soil condition in which seismically induced ground motion causes an increase in soil water pressure in saturated, loose, uniformly-graded sands, resulting in loss of soil shear strength. As a result, the effects of liquefaction can include loss of bearing strength, differential settlement, ground oscillations, lateral spreading, and flow failures or slumping. Liquefaction occurs primarily in areas where the groundwater table is within approximately 50 feet of the surface (Riverside County, 2008). The depth to water beneath the Site is estimated to be approximately 195 feet bgs. In addition, the sandy soils encountered in the upper 100 feet beneath the Project site during geotechnical drilling are generally dense and well graded. Dense, well-graded sands are not generally considered susceptible to liquefaction. Based on this information and engineering judgment, the potential for liquefaction hazard at the Project site is considered to be low. The potential for liquefaction will be further evaluated as part of the Final Geotechnical Investigation for the Project, and if necessary, design parameters to address identified conditions will be incorporated into the detailed project design.

Differential Settlement

~~38~~**37**. Seismically induced settlement can occur during moderate and large earthquakes in soft or loose, natural or fill soils that are located above the ground water table, resulting in differential settlement. The settlement can cause damage to surface and near-surface structures. The most susceptible soils are clean loose granular soils. Due to the expected dense to very dense nature of the near surface soils, the potential for damage due to seismically induced settlement is considered to be low at the Project site. The potential for seismically-induced settlement will be further evaluated as part of the Final Geotechnical Investigation for the Project, and if necessary, design parameters to address identified conditions will be incorporated into the detailed project design.

Collapsible Soil Conditions

~~39~~**38**. Alluvial soils in arid and semi-arid environments can have characteristics that make them prone to collapse with increase in moisture content and without increase in external loads. Soils that are especially susceptible to collapse or hydrocompaction in a desert environment are loose dry sands and silts, and soils that contain a significant fraction of water soluble salts. Overall soil gradation observed at the Facility site trended from coarser- to finer-grained alluvial deposits as distance from the McCoy Mountains increased. The ground surface in the western portion of the Project site is dominated by areas of desert pavement with layers of flat-lying gravel overlying finer-grained sandy materials. East toward Black Creek road, the surface becomes less dominated by desert pavement and becomes sandier. Soils observed at the Facility site have a low permeability and high runoff potential. Based on this data and engineering judgment, the site soils do not have a significant potential for hydrocompaction or collapse. The potential for hydrocompaction and soil collapse will be further evaluated as part of the Final Geotechnical Investigation for the Project, and if necessary, design parameters to address identified conditions will be incorporated into the detailed project design.

Expansive Soil

~~40~~**39**. Expansive soil is predominantly fine grained and contains clay minerals capable of absorbing water in their crystal structure. It is often found in areas that were historically a flood plain or lake area, but can also be associated with some types of shale, volcanic ash or other deposits, and can occur in hillside areas also. Expansive soil is subject to swelling and shrinkage, varying in proportion to the amount of moisture present in the soil. As water is initially introduced into the soil (by rainfall or watering) expansion takes place. If dried out, the soil will contract, often leaving small fissures or cracks. Excessive drying and wetting of the soil can progressively deteriorate structures that are not designed to resist this effect, and can lead to differential settlement under buildings and other improvements. The surficial soils at the site generally consist of predominantly granular soils that do not contain much clay and are not subject to significant expansion hazards. The potential for expansive soils will be further evaluated as part of the Final Geotechnical Investigation for the Project, and if necessary, design parameters to address identified conditions will be incorporated into the detailed project design.

~~41~~**40**. Based on the above information, the cut and fill slope dimensions and earthwork requirements will be adequate to address the stability of the evaporation ponds ~~and LTU~~ for the life of the ~~p~~**P**roject and no further analysis is warranted.

Regional Hydrogeology

~~42~~**41**. The Recent-age (~11,000 years) younger alluvium consists of poorly-sorted gravel, sand, silt, and clay. The younger alluvium overlies the older geologic units as a thin veneer and is believed to be mostly above the water table. The Recent-age playa deposits consist mainly of clay, silt, and sand and occur in Ford and Palen Lakes and Hayfield Reservoir. During recent history, groundwater levels were shallower and groundwater likely discharged to Palen Dry Lake. Regional water level data suggests that water is possibly shallower than 25 feet below Palen Dry Lake, a depth which would suggest water may be lost or discharged through evapotranspiration. Recent groundwater levels below Ford Dry Lake show the water to be about 50 feet below the surface of the lake. At this depth, it is unlikely that water is lost through evapotranspiration. The dune sand deposits occur on the lower elevations of the valley from the northwest end of Chuckwalla Valley to the eastern end of the valley, and just northeast of the Project site.

~~43~~**42**. The older alluvium generally consists of fine to coarse sand inter-bedded with gravel, silt, and clay. The color ranges from dark brown to red, with abundant small white caliche nodules. This unit is assumed to be extensive, readily yields water to wells, and is considered the most important aquifer in the Chuckwalla Valley Groundwater Basin. It is believed that saturated sediments below the side to a depth of about 500 feet are older alluvial deposits.

Hydrostratigraphy

~~44~~**43**. The Pinto Formation consists of coarse fanglomerate and lacustrine clay with interbedded basalt. The DWR suggests (2004) that this unit yields limited quantities of water. Below the Pinto Formation, the PlioPleistocene Bouse Formation is comprised predominantly of coarse-grained fanglomerate deposits.

~~45~~**44**. Well logs were located through reports published by the DWR and through information provided in various reports. There are two wells on the Project site and one has a boring log with lithologic information available in a reported prepared by the DWR. The log for well 5S/17E-33N001 indicated surficial sands were encountered from the ground surface to 102 feet bgs; 18 feet of clay, sand and gravel were encountered from 102 feet to 120 feet bgs; clay was encountered between 120 and 208 feet bgs, sand and gravel were encountered from 208 to 216 feet bgs; clay streaks and sand were encountered from 216 feet to 556 feet bgs; and sand streaks and “sandstone cappings” were encountered within predominantly fine-grained materials between 556 feet and 758 feet bgs. It is possible that sediments encountered to a depth of 556feet bgs area older alluvial deposits. The log of well 5S/17E-33N001 does not have sufficient detail to readily discern the contact between the units reported for the Chuckwalla Valley Groundwater Basin.

~~46~~**45**. Boring logs could be found for only approximately 10 percent of the wells that were identified from an online database and literature within the basin. Available information provided in these logs was used to provide an understanding of subsurface conditions and develop a generalized geologic cross section for the Chuckwalla Valley Groundwater Basin. The limited geologic data revealed general variations in the sediments from the west to the east. In general, very few wells were drilled to the top of the basement or base of the fresh water in the Chuckwalla Valley Groundwater Basin. One well located on the eastern edge of the basin, due west of the gap to the Palo Verde Groundwater Basin, was drilled to a depth of about 1,200 feet bgs, where it encountered bedrock.

~~47~~**46**. In general, sediments on the western and eastern portions of the valley, and along the fringes of the basin are comprised of a higher percentage of coarsegrained sediments. These deposits are the proximal facies of coalescing alluvial fans. In the central portion of the valley and below the Project, sediments are generally composed of a much higher percentage of clay with subordinate amount of sand that occurs as layered inter-beds. These deposits have been interpreted as lacustrine deposits in the central portion of the basin. The wells located along the central portion of the valley and shown on the axial cross section through the valley appear to be completed within an inter-bedded sequence of alluvial fan and lacustrine deposits. Shallow sediment encountered below the Project consisted of very fine-grained silty sand and sand, suggesting distal fan facies. Interbedded clay with these sediments is probably lacustrine deposits. While the data is not conclusive these deposits to a depth of 538 feet are probably in the older alluvium.

~~48~~**47**. The basal portion of may be upper portions of the Bouse Formation. The deeper Fanglomerate was not encountered and it is likely that the Pinto Formation was also not found below the Project site based on the absence of interbedded basalt deposits.

On-site Drainage

~~49~~**48**. On-site storm water management for the completed facility will be provided through the use of source control techniques, site design and treatment control. The storm flows from the solar collector arrays will be treated through the use of swales, and ditches.

~~50~~**49**. Locations within the power block for the potential of chemical or oil releases will be fully contained. Rainfall within the containment areas will be allowed to evaporate or will be drained through an oil water separator. Locations within the power block where “contact” storm water may occur will be contained within a system of curbs or trenches. Drains from these curbed areas or containment trenches will be directed to an oil water separator. The oil separated and captured within the oil water separator will be trucked off-site to a licensed disposal/recycling facility. Clean water discharged from the oil water separator will be used on Project site by discharging it to the cooling tower or to the raw water storage tank. The water discharge from the oil water separator will not be discharged to the storm water system.

Facility Operational Water

~~51~~**50**. The Project will be dry cooled. The Project's various water uses include water for solar collector mirror washing, makeup for the SSG feed water, dust control, water for cooling plant auxiliary equipment, potable water and fire protection. Water needs for the Project will be met by use of groundwater pumped from wells on the Project site. The estimated water supply need for the Project operation is approximately 300 acre-feet per year.

Evaporation Ponds (Design and Installation Sequence)

~~52~~**51**. The containment strategy for the evaporation ponds is summarized as follows:

a. Meet or exceed regulatory requirements for containment of waste fluids;

b. Select materials that are compatible with the physical, chemical and thermal characteristics of the water and contaminated soils being contained;

c. Protect against physical damage to the containment layers by including protective layers into the designs of each containment facility;

d. Allow for occasional removal of contained media without otherwise damaging the integrity of the containment systems; and

e. Include the ability to monitor the integrity of the containment system, to transfer fluids out of permeable layers on a continuous basis, and to transfer fluids from one evaporation pond to another.

~~53~~**52**. Each ~~4~~**2**.0 acre evaporation pond has a proposed design depth of seven feet which incorporates:

a. Drying each pond at alternating four year intervals;

b. 3 feet of operational depth;

c. 2 foot of sludge build up over 4 years; and

d. 2 feet of freeboard.

~~54~~**53**. The containment design for the evaporation ponds, from the surface of the evaporation ponds downwards, consists of the following:

a. A hard surface / protective layer;

b. A primary 60 mil high density polyethylene (HDPE) liner;

c. An interstitial leak detection system (LDS) comprising a drainage layer and piping;

d. A secondary 40 mil HDPE liner; ~~and~~

e. A 2 foot thick compacted silty-sand base**; and**

f. A moisture detection system.

~~55~~**54**. The hard surface / protective layer provides protection against accidental damage to the HDPE liners which could be caused by burrowing animals, falling objects, varying climatic conditions and worker activities. Second, the hard surface / protective layer will allow for occasional removal of the precipitated solids within the evaporation ponds. Various hard surface media such as reinforced concrete, roller compacted concrete, revetments, or combinations of these media will be assessed prior to the selection of the preferred option.

~~56~~**55**. High density polyethylene (HDPE) was selected as the preferred fabric for the primary and secondary liners for the following reasons:

a. It is chemically resistant to potentially high concentrations of dissolved salts;

b. It is very durable during installation;

c. It is strong and possesses desirable stress-strain characteristics; and

d. It is the most common synthetic liner material and as such there is a broad base of practical experience associated with the installation of HDPE amongst construction contractors.

~~57~~**56**. A 60 mil upper liner was selected to provide appropriate balance between strength and ductility characteristics, which is very important during liner installation. A non-woven geotextile will be installed on top of the 60 mil liner to act primarily as a protective layer. A 40 mil lower liner was selected for the lower and secondary liner to provide slightly better ductility and handling characteristics during installation, as strength is of lesser importance for the secondary liner. HDPE possesses large thermal expansion and contraction characteristics, and exhibits stress when liner temperature exceeds 122 ºF. The temperature of the blowdown water is not expected to exceed 122ºF.

~~58~~**57**. A 2 foot thick basal layer of compacted silty sand is included in the design profile to protect the underlying groundwater in the unlikely event that both synthetic liner materials are punctured during construction or operation of the evaporation ponds. This base layer also serves to provide a smooth, competent surface to support the overlying synthetic liners and leak detection system layers.

Leak Detection System

~~59~~**58**. A drainage layer is included in the design profile for the evaporation ponds which consists of a granular drainage layer with perforated piping to collect and convey fluids to an extraction riser in a leak detection sump (LDS). Geocomposite drainage materials, consisting of HDPE geonet and nonwoven geotextiles heat bonded to one or both sides, may be used in conjunction with or as a substitute for the granular drainage layer on slopes.

~~60~~**59**. The water collected in the LDS will drain by gravity to a unique monitoring well that is constructed for each of the leak collection layer. Automated pneumatic, solar-powered pumping systems are included in the design of each of these monitoring wells to automatically return water to that pond, which in turn minimizes the hydraulic pressures across the secondary liners and therefore the risk of impact to groundwater quality.

~~61~~**60**. The base of the evaporation pond leak detection and collection layer will slope at a minimum inclination of 1 percent to a leak collection trench. The trench will contain screened sand (with no fines) and a perforated pipe that will slope at a minimum inclination of 3/4 percent towards a leak detection and collection sump, located at the lowest point in the pond. The water in the collection sump will drain by gravity to a monitoring well that is constructed for each evaporation pond (one well per pond). Automated pneumatic pumping systems in the monitoring wells will automatically return water collected in the sump to that evaporation pond, which in turn minimizes the hydraulic pressures across the secondary liners and, therefore, minimizes the risk of leakage through the secondary liner. Leakage rates will be measured using a flow totalizer.

~~62~~**61**. The collection sump, pipe, and monitoring well, will include prefabricated and field-fabricated HDPE components with water tight, extrusion welded and wedge-welded seams and penetrations. The liner system will be installed in accordance with current practices. Destructive and non-destructive testing procedures will be used to verify sump and penetration tightness and continuity.

~~63~~**62**. This design is consistent with CCR Title 27, Section 20340, which requires an LDRS between the liners for the evaporation ponds.

~~64~~**63**. The side slopes around the evaporation ponds will contain the same liner system as the base of the ponds, except that leak collection pipes will not be located on the pond side slopes.

~~65~~**64**. The berms shall be covered with a minimum 6-inch thick road base or approved equivalent. The top of the berms will be a minimum of 2 feet above the surrounding grade to prevent potential inflow of stormwater.

~~66~~**65**. The wastewater will come into contact with the hard surface/protective layer. The media for this layer will either be roller-compacted concrete or an approved equivalent alternate. All final media selection will be compatible with the wastewater by using quality concrete with maximum chemical resistance (specifications will be provided to the concrete manufacturer to ensure proper mix selection).

~~67~~**66**. If there is leakage in the evaporation pond, the wastewater will come into contact with the primary/secondary liner. HDPE is chemically resistant to saline solutions and long-term contact between the wastewater in the evaporation ponds and the HDPE liner system will not compromise liner integrity.

~~68~~**67**. The hard surface/protective layers, liner system, and base layer will have the ability to withstand the dissolved solids content of the water without degradation. These systems will not fail due to pressure gradients from physical contact with the wastewater and residue or undergo chemical reactions or degradation.

~~69~~**68**. The containment construction process will follow these general steps:

a. Prior to construction, the topsoil and subsoil covering the area will be stripped and stockpiled.

b. Placement and compaction of the silty sand base material;

c. Installation of the carrier pipe for the moisture detection (neutron probe) system beneath the base of the ponds;

d. Construction of finish grading to sub grade, as needed, and excavation of the leak collection trench and detection/collection sumps.

e. Scarification, moisture conditioning, compaction, proof rolling and testing of subgrade materials;

f. Installation of secondary HDPE liner;

g. Installation of leak detection layer, sump, and leak extraction risers;

h. Installation of primary HDPE liner;

i. Installation of the non-woven geomembrane liner;

j. Installation of granular fill;

k. Installation of liner protection layers; and

l. Hard surface placement.

Waste Classification

~~70~~**69**. Wastewater from several processes within the Facility will be piped to ~~two~~ one ~~4~~**2**.0- acre evaporation ponds per Unit ~~(total combined area of 8 acres per Unit)~~ for disposal. The pond area provides sufficient evaporative capacity to dispose of the anticipated wastewater stream, and allows for one pond to be taken out of service for up to approximately eight months for cleaning, potential future maintenance, and repair without impacting the operation of the plant. Raw water for the Facility is supplied from groundwater wells. Discharge into the evaporation ponds is from ~~two~~ **one** sources~~s~~:

a. High pH RO (Reverse Osmosis Concentrate**)**~~; and~~**.**

Wastewater Discharge

~~71~~**<u>70</u>**. The estimated concentrations of chemical constituents in the wastewater discharge to the evaporation ponds are provided in the **Table 1**, Raw Water Quality and Estimated Chemistry of Wastewater Flows. The total concentrations of chemical constituents estimated in the evaporation pond residue that will accumulate in the ponds during operation are provided in **Table 2**.

~~72~~**<u>71</u>**. Classification of wastewater and evaporation pond residue is summarized in the Classification of Wastewater and Evaporation Pond Residue **Table 3** below.

~~73~~**<u>72</u>**. Testing of this material will be conducted as part of the facility monitoring program to verify this characterization. The evaporation pond residue accumulated in the ponds is non hazardous; however, it does contain pollutants which could exceed water quality objectives if released, or that could be expected to affect the beneficial uses of waters of the state. Therefore, the evaporation pond residue is classified as a "designated waste."

Evaporation Residue

~~74~~**<u>73</u>**. During the 30-year operating life of the Project, about 6,400 tons of evaporites will accumulate in the ponds. However, because it is anticipated that windblown silt will accumulate in the ponds at a rate of perhaps 6 inches per year, it will be necessary to clean out the ponds on approximately four-year intervals. Assuming 2 feet of silt accumulation, the sludge removed from the ponds will be approximately nine percent evaporate and 91 percent silt. The predicted chemical makeup of the evaporite, based on information about the raw water chemistry and knowledge of the water use and treatment processes at the Project, is summarized in **Soil and Water Resources Appendix B Table 3**.

~~**Land Treatment Unit**~~

~~75. In compliance with Table 2.1 in CCR Title 27, Chapter 3, Subchapter 2, Article 2, Section 20210, solid designated wastes will be managed in full containment in a Class II LTU with a single liner system. The LTUs will be constructed to be above the level of a 100-year storm event and designed to meet seismic hazard criteria. In addition, the base of the LTUs will have a greater than 5-foot separation to the underlying groundwater. The location of the east and west LTUs are shown on **Figure 2**.~~

~~76. The LTU will not incorporate a liner containment system or leak detection and removal system, but will be constructed with a prepared base consisting of 2 feet of compacted, low permeability, lime-treated material. This base will serve as a competent platform for land treatment activities, and will serve to slow the rate of surface water infiltration in the treatment area. The compacted lime-treated and native soil beneath the LTU is designated as a "treatment zone" to a depth of 5 feet. Although the LTU will be taking vehicle traffic, no hard surface will be required, as there is no liner system to protect. A staging area is allocated in the LTU for storage of HTF-impacted soils while they are being characterized. Soil characterized as hazardous will be removed from the site; therefore, no additional liner system is required in the LTU to cater for the hazardous waste.~~

77. ~~The LTU will be surrounded on all sides by a 2-foot high compacted earthen berm with side slopes of approximately 3:1 (horizontal: vertical). These berms will control and prevent potential inflow (run on) of surface storm water into the LTU or runoff of storm water from the unit.~~

78. ~~The LTUs are sized based on data from an existing solar farm that uses an LTU to bioremediate HTF-impacted soil and the following basis:~~

    a. ~~HTF-impacted soil is generated at a rate consistent with existing solar farm experience. Kramer Junction is a 150 MW facility that generates an average of 500 cubic yards (cyd) of HTF-impacted soil per year (DTSC correspondence, 1995). This rate is approximately 3.3 cyd/year/MW.~~

    b. ~~Applying the Kramer Junction experience to the 500 MW Palen facility, the Palen facility is estimated to generate ~1,666 cyd/year of HTFimpacted soil.~~

    c. ~~HTF-impacted soil is treated in 6-inches thicknesses, so, on average, 90,000 square feet or 2.1 acres is needed for HTF-impacted generated per year.~~

    d. ~~The LTU will be used for either placement of HTF-impacted soil or treatment of HTF-impacted soil. That is at any one time the LTU is used to place material to be treated as it is generated or being used for soil treatment. HTF-impacted soil treatment is estimate to take 1 to 4 months to complete bio remediation; however the design of the LTU will allow soil placed at the beginning of the year to have up to twelve months to complete bioremediation and removal.~~

    e. ~~To address above average spill events, Kramer Junction has additional capacity in the LTU or a factor of safety for HTF-impacted soil treatment. Kramer Junction has a capacity to treat 1,944 cyd/year and generates an average of 500 cyd/year of HTF-impacted soil, so the facility has ~ a 3.9 factor of safety. Applying this factor of safety to Palen, the total area estimated for LTU is approximately 350,000 square feet or 8 acres~~

79. ~~Treatment of HTF-impacted soil in the LTU will involve moisture conditioning and may involve addition of nitrogen and phosphorous nutrients (i.e., fertilizers) as needed to stimulate consumption of HTF by the indigenous bacteria. The HTF-impacted soil will be moisture conditioned and turned periodically as needed to enhance aeration, promote breakdown of HTF by the indigenous bacteria and/or to control dust emissions. Permanent or portable irrigation sprinklers will supply water to the area for dust control and to assist in treatment.~~

80. ~~Treatment piles may be covered by plastic sheeting as needed to enhance temperature and moisture retention characteristics, and as needed to control storm water contact, odors and dust emissions.~~

81. ~~The base layer construction process will follow these general steps:~~

a. ~~Prior to construction, the LTU will be stripped, grubbed and cleared of topsoil;~~

b. ~~General excavation and grading to sub grade will take place as needed;~~

c. ~~Scarification and moisture conditioning of sub grade materials will take place; and~~

d. ~~Placement, moisture conditioning, lime treatment, and compaction of native clayey silt material to form the base and perimeter berms will be completed before proof rolling after finish grading.~~

82. ~~The LTU pad and berm construction will use standard cut and fill techniques. Native clayey silt material will be used to construct the pad and berms. The clayey silt material will be moisture conditioned and treated with at least 2 percent quicklime to achieve an R-Value of at least 40 to 50. Treatment and compaction of the material will be conducted using standard commercial lime treatment methods and equipment and compacted in lifts using a sheeps foot roller. The lime treated layer will be compacted to a minimum of 95 percent of the maximum dry density as determined by American Standard for Testing and Materials (ASTM) D1557. Field testing of the density of the soil will be performed at regular intervals. Compaction results will be recorded. After finish grading, the surface of the LTU pad and berms will be proof rolled.~~

~~Waste Classification~~

83. ~~The HTF-affected soils will be characterized as hazardous or non hazardous waste prior to determination of whether the material can be treated at the LTU or must be removed for off-site disposal. Therefore, HTF affected soils will be relocated to a temporary staging area in the LTU and characterized consistent with U.S. Environmental Protection Agency (EPA) protocols. Soil sample of excavated HTF-affected soil will be collected in accordance with the EPA's current version of the manual "Test Methods for Evaluating Solid Waste" (SW- 846) and the waste material will be characterized in accordance with State and Federal requirements. Soil samples will be analyzed for HTF constituents (Biphenyl and Diphenyl Ether) using modified EPA Method Modified 8015.~~

84. ~~Prior to operation of the LTU and initiation of any on-site remediation of HTF, the waste stream will be characterized and a waste classification determination rendered by the DTSC. Initially, in addition to sampling for HTF, soil samples will also be analyzed for ignitability and toxicity using appropriate State and Federal methods to characterize the waste as hazardous or non-hazardous. Once a sufficient data set has been accumulated to allow characterization of the material as hazardous or non-hazardous waste based on HTF content and generator knowledge, the DTSC will be petitioned for a determination of waste classification for HTF-affected soils generated at the facility. Following this determination, subsequent samples will only be analyzed for HTF to determine disposition of the waste either for remediation or for transportation and disposal off-site. If the soil is characterized~~

~~as a hazardous waste, the impacted soils will be transported from the site by a licensed hazardous waste hauler for disposal at a licensed hazardous waste landfill or treatment storage and disposal facility (TSDF).~~

85. ~~Based on the classification practice and management of similar waste stream at the Kramer Junction Solar Electric Generating System (SEGS) facility in Kern County, it is anticipated that soil containing 10,000 mg/kg HTF or more will be managed as hazardous waste, and that soil containing less than 10,000 mg/kg HTF will be non-hazardous waste and can be managed at the site. At the Kramer Junction facility, the DTSC issued a letter dated April 4, 1995, stating that soil contaminated with HTF "poses an insignificant hazard" and classifies the waste as non-hazardous for soils with a concentration of less than 10,000 mg/kg HTF pursuant to CCR Title 22, Section 66260.200(f). Given that the formulation of HTF has not changed significantly since this determination, it is anticipated that future waste characterization at PSPP will yield a similar result although the DTSC has indicated that this decision will be made on a project specific basis and the Kramer Junction classification does not necessarily ensure the same classification for the PSPP.~~

86. ~~All HTF-affected soil classified as a hazardous waste will be removed for the site for proper off-site disposal; therefore the material in the LTU will be managed as a non-hazardous "designated waste" as defined in CCR Title 23, Chapter 15, Section 2522. Based on waste discharge requirements for similar sites, soil containing HTF in concentrations less than 100 mg/kg will not be regulated as a waste and could be reused as fill on-site.~~

~~Waste Management~~

87. ~~The LTU will be used to treat HTF-affected soil at various concentrations. Spills of HTF will be cleaned up within 48 hours and affected soil will be moved to a temporary staging area in the LTU where it will be placed on 60-mil plastic and covered with plastic sheeting pending receipt of analytical results and characterization of the waste material. As possible, free liquids will be removed using a vacuum truck. The liquids will be filtered and reused to the extent possible and reintroduced into the process. Filtrate that cannot be reused will be characterized, as appropriate though will likely be managed as hazardous waste, as the concentration in the filtrate will likely be more than 10,000 mg/kg HTF.~~

88. ~~No HTF-affected soils characterized as hazardous waste will be disposed or treated on-site. As stated previously, it is anticipated that soil containing 10,000 mg/kg HTF or more will be managed as hazardous waste, and that soil containing less than 10,000 mg/kg HTF will be managed at the site as nonhazardous waste. If the soil is characterized as a non-hazardous waste, it will be spread in the LTU for bioremediation treatment. In general, within the LTU, more highly contaminated soil will be covered with plastic sheeting to prevent contact with storm water and to control potential odors and emissions, as well as for moisture and temperature retention. Once the soil has been treated to a concentration of less than 100 mg/kg HTF, it will be moved from the LTU to another portion of the site until it is reused at the Project site as fill material.~~

~~89. Based on available operation data from other sites, it is anticipated that approximately 1,666 cubic yards (on average) of HTF-affected soil may be treated per year. Larger or smaller quantities could be generated during some years, depending on the frequency and size of leaks and spills.~~

~~90~~**74**. A Spill Prevention, Control, and Countermeasure (SPCC) Plan will be developed for the Project (refer to Section 13.4 for details). ~~Periodically, equipment failures in and around mirror fields are expected at the Project that may result in spills of HTF onto soil.~~

~~91. Excess wastewater or rain fall may occasionally accumulate in the LTU. The LTU has been constructed with 2-foot high berms such that storm water will not drain into or from the LTU. Based on the frequency of storms in the area, it is anticipated accumulation of rainwater within the containment would occur on a yearly basis. Water that accumulates within the LTU will be sampled for HTF and amendments. If HTF is not detected above the practical quantitation limit (PQL) and amendment concentrations (i.e., nitrate, phosphate, TDS) are at or near background groundwater concentrations and below State of California primary or secondary maximum contaminant levels the water may be reused in the plant process. If HTF is detected and amendment concentrations exceed background or drinking water standards the waste will be properly disposed of at a licensed TSDF.~~

Hazardous Waste

~~92~~**75**. There will be a variety of chemicals stored and used during construction and operation of the project. The storage, handling, and use of all chemicals will be conducted in accordance with applicable laws, ordinances, regulations, and standards.

~~93~~**76**. Hazardous materials will be stored in proper containers in material yards and designated construction areas. Cleanup materials (spill kits) will also be stored in these areas. Fuel, oil, and hydraulic fluids used in on-site vehicles will be transferred directly from a service truck to construction equipment and will not otherwise be stored on-site.

~~94~~**77**. Designated, trained service personnel will perform fueling either prior to the start of the workday or at completion of the workday. Service personnel and construction contractors will follow SOPs for filling and servicing construction equipment and vehicles.

~~95~~**78**. ~~Any HTF impacted soil classified as hazardous will be removed from the LTU staging area after the initial characterization~~. The evaporation ponds will not contain hazardous wastewater or sludge as it is illegal to discharge hazardous waste into surface impoundments under the Toxic Pits Cleanup Act of 1984.

Basin Plan

~~96~~**79**. The Water Quality Control Plan for the Colorado River Basin Region of California (Basin Plan) was adopted on November 17, 1993, and designates the beneficial uses of ground and surface water in this Region.

~~97~~**80**. The Basin Plan designates beneficial uses for surface waters in each watershed of the Colorado River Basin region. Beneficial uses of surface waters within the Facility area and vicinity that could be impacted by the Facility include:

a. Agricultural use

b. Municipal use

c. Industrial use

d. Recreational use

e. Groundwater recharge

f. Wildlife habitat

g. Preservation of Rare, Threatened, or Endangered Species

~~98~~**81**. The beneficial uses of ground water in the Imperial Hydrological Unit are:

a. Municipal Supply (MUN)

b. Industrial Supply (IND)

c. Agricultural supply

Monitoring Parameters

~~99~~**82**. Based on the chemical characteristics of the projected discharges to the evaporation ponds from wastewater, the following list of monitoring parameters are required. These specific parameters are selected because they provide the best distinction between the wastewater and the groundwater in the Project area that can be used to differentiate a potential release that could change the chemical composition of the groundwater.

a. Cations: Antimony, Arsenic, Barium, Cadmium, Calcium, Total Chromium, Cobalt, Copper, Lead, Mercury, Nickel, Selenium, Zinc;

b. Anions: Chloride and Sulfate; and

c. Other: ~~HTF~~, Total Dissolved Solids, Specific Conductivity, and pH.

California Environmental Quality Act (CEQA)

~~100~~**83** The California Energy Commission (CEC) is the lead agency under the California Environmental Quality Act (CEQA) (Public Resources Code Section 21000 et seq.) for all thermal power plants with power ratings of 50 MW or more. The CEC's power plant licensing process is a CEQA-equivalent process. The CEC will coordinate reviews and approvals with the regulatory agencies to ensure that the proposed project meets CEQA requirements. This includes obtaining these WDRs from the staff of the Regional Board. The CEC will certify this project and will include these WDRs as conditions of certification in accordance with the Warren-Alquist Act.[24]

Monitoring and Reporting Program

~~101~~**84** The monitoring and reporting requirements in the Monitoring and Reporting Program (Appendix D), and the requirement to install groundwater monitoring wells, are necessary to determine compliance with these WDRs, and to determine the Facility's impacts, if any, on receiving water. **All technical reports require the signature of a California Registered Professional Engineer or Professional Geologist.**

[24] The Warren-Alquist State Energy Resources Conservation and Development Act is the authorizing legislation for the California Energy Commission. The Act is codified at Public Resources Code (PRC) Section 25000 et seq.. PRC Section 25500 establishes the Commission's authority to certify all sites and related facilities for thermal power plants with power ratings of 50 megawatts or more. The section further declares that "the issuance of a certificate by the commission shall be in lieu of any permit, certificate, or similar document required by any state, local or regional agency, or federal agency to the extent permitted by federal law, for such use of the site and related facilities, and shall supersede any applicable statute, ordinance, or regulation of any state, local, or regional agency, or federal agency to the extent permitted by federal law."

SOIL AND WATER RESOURCES – APPENDIX C

Staff has proposed modifications to the **Soil & Water Resources – Appendix C** as shown below. (**Note:** Deleted text is in ~~strikethrough~~, new text is **<u>bold and underlined</u>**)

REQUIREMENTS FOR WASTE DISCHARGE - Palen Solar ~~I~~<u>Holdings</u>, LLC, Owner/Operator, Palen Solar ~~Power Project~~ <u>Electric Generating System</u>, Riverside County

A. Discharge Specifications

1. The treatment or disposal of wastes at this Facility shall not cause pollution or nuisance as defined in Sections 13050 of Division 7 of the California Water Code (CWC).

2. The Discharger will maintain the monitoring wells in good working order at all times. Well maintenance may include periodic well re-development to remove sediments.

3. Thirty **<u>(30)</u>** days prior to introduction of a new waste stream into the evaporation ponds, the Discharger must receive approval from the Regional Board's Executive Officer.

4. Waste material shall be confined or discharged to the evaporation ~~ponds and LTU~~.

5. Prior to drilling a new well or abandoning a well at the Facility, the Discharger shall notify, in writing, the Regional Board's Executive Officer of the proposed change.

6. Containment of waste shall be limited to the areas designated for such activities. Any revision or modification of the designated waste containment area, or any proposed change in operation at the Facility that changes the nature and constituents of the waste produced must be submitted in writing to the Regional Board's Executive Officer for review and approval before the proposed change in operations or modification of the designated area is implemented.

7. Any substantial increase or change in the annual average volume of material to be discharged under this order at the Facility must be submitted in writing to the Regional Board's Executive Officer for review and approval.

8. If any portions of the evaporation ponds are to be closed, the Discharger shall notify the Regional Board's Executive Officer at least 180 days prior to beginning any partial or final closure activities.

9. Fluids and/or materials discharged to and/or contained in the evaporation ponds shall not overflow the ponds.

10. Prior to the use of new chemicals for the purposes of adjustment or control of microbes, pH, scale, and corrosion of the cooling tower water and wastewater, the Discharger shall notify the Regional Board's Executive Officer in writing.

11. For the liquids in the evaporation ponds, a minimum freeboard of two (2) feet shall be maintained at all times.

12. Final disposal of residual waste from cleanup of the evaporation ponds shall be accomplished to the satisfaction of the Regional Board's Executive Officer upon abandonment or closure of operations.

13. The evaporation ponds shall be designed, constructed, operated, and maintained to prevent inundation or washout due to floods having a predicted frequency of once in 100 years.

14. Prior to removal of solid material that has accumulated in the evaporation ponds, an analysis of the material must be conducted and the material must be disposed of in a manner consistent with that analysis and applicable laws and regulations.

15. Conveyance systems throughout the Facility area shall be cleaned out at least every 90 days to prevent the buildup of solids.

16. Pipe maintenance and de-scaling activities that include hydroblasting and/or sandblasting shall be performed within a designated area that minimizes the potential for release to the environment. Waste generated as a result of these activities shall be disposed of in accordance with applicable laws and regulations. Water from the hydroblasting process shall be conveyed to the evaporation ponds.

17. Public contact with wastewater shall be precluded through such means as fences, signs, or other acceptable alternatives.

18. The evaporations ponds shall be managed and maintained to ensure their effectiveness, in particular,

19. Implementation of erosion control measures shall assure that small coves and irregularities are not created.

20. The liner beneath the evaporation ponds shall be appropriately maintained to ensure its proper functioning.

21. Solid material shall be removed from the evaporation ponds in a manner that minimizes the likelihood of damage to the liner.

22. Ninety **<u>(90)</u>** days prior to the cessation of discharge operations at the Facility, the Discharger shall submit a workplan, subject to approval of the Regional Board's Executive Officer, for assessing the extent, if any, of contamination of natural geological materials and waters of the Chuckwalla Valley Groundwater Basin by the waste. One hundred twenty **<u>(120)</u>** days following workplan approval, the Discharger shall submit a technical report presenting results of the contamination assessment. A California Registered Civil Engineer or Certified Engineering Geologist must prepare the workplan, contamination assessment, and engineering report.

23. Upon ceasing operation at the Facility, all waste, all natural geologic material contaminated by waste, and all surplus or unprocessed material shall be removed from the site and disposed of in accordance with applicable laws and regulations.

24. The Discharger shall establish an irrevocable bond for closure in an amount acceptable to the Regional Board's Executive Officer or provide other means to ensure financial security for closure if closure is needed at the discharging site. The closure fund shall be established (or evidence of an existing closure fund shall be provided) within six (6) months of the adoption of this Order.

25. Surface drainage from tributary areas or subsurface sources, shall not contact or percolate through the waste discharged at this site.

26. The Discharger shall implement the attached Monitoring and Reporting Program, Appendix D, and revisions thereto, in order to detect, at the earliest opportunity, any unauthorized discharge of waste constituents from the Facility, or any impairment of beneficial uses associated with (caused by) discharges of waste to the brine pond.

27. The Discharger shall use the constituents listed in the attached Monitoring and Reporting Program, Appendix D, and revisions thereto, as "Monitoring Parameters".

28. The Discharger shall follow the Water Quality Protection Standard (WQPS) for detection monitoring established by the Regional Board. The following are parts of WQPS as established by the Regional Board's Executive Officer:

    a. The Discharger shall test for the monitoring parameters and the Constituents of Concern (COCs) listed in the Monitoring and Reporting R7-2010-0xxx and revisions thereto.

    b. Concentration Limits – The concentration limit for each monitoring parameter and constituents of concern for each monitoring point (as stated in the Detection Monitoring Program), shall be its statically determined background value or method detection limit, whichever is higher as obtained during that reporting period.

29. All current, revised, and/or proposed monitoring points must be approved by the Region Board's Executive Officer.

30. Water used for the process and site maintenance shall be limited to the amount necessary in the process, for dust control, and for Facility cleanup and maintenance.

31. The Discharger shall not cause or permit the release of pollutants, or waste constituents, in a manner which could cause or contribute to a condition of contamination, nuisance, or pollution to occur.

32. The Discharger must develop and implement a Hazardous Materials Business Plan (HMBP), which will include, at a minimum, procedures for:

    a. Hazardous materials handling, use, and storage;

    b. Emergency response;

    c. Spill control and prevention;

    d. Employee training; and

    e. Reporting and record keeping.

33. Hazardous materials expected to be used during construction include: unleaded gasoline, diesel fuel, oil, lubricants (i.e., motor oil, transmission fluid, and hydraulic fluid), solvents, adhesives, and paint materials. There are no feasible alternatives to these materials for construction or operation of construction vehicles and equipment, or for painting and caulking buildings and equipment.

34. The construction contractor will be responsible for assuring that the use, storage and handling of these materials will comply with applicable federal, state, and local laws, ordinances, regulations and standards (LORS), including licensing, personnel training, accumulation limits, reporting requirements, and recordkeeping.

35. During Facility operations, chemicals will be stored in chemical storage areas appropriately designed for their individual characteristics. Bulk chemicals will be stored outdoors on impervious surfaces in aboveground storage tanks with secondary containment. Secondary containment areas for bulk storage tanks will not have drains. Any chemical spills in these areas will be removed with portable equipment and reused or disposed of properly. Other chemicals will be stored and used in their delivery containers.

36. A portable storage trailer may be on-site for storage of maintenance lube oils, chemicals, paints, and other construction materials, as needed. All drains and vent piping for volatile chemicals will be trapped and isolated from other drains to eliminate noxious vapors. The storage, containment, handling, and use of these chemicals will be managed in accordance with applicable laws, ordinances, regulations, and standards.

37. Small quantities of hazardous wastes will be generated over the course of construction. These may include paint, spent solvents, and spent welding materials. Some hazardous wastes will be recycled, including used oils from equipment maintenance, and oil-contaminated materials such as spent oil filters, rags, or other cleanup materials. Used oil must be recycled, and oil or heavy metal contaminated materials (e.g., filters) requiring disposal must be disposed of in a Class I waste disposal facility. Scale from pipe and equipment cleaning operations, and solids from the evaporation pond, will be disposed of in a similar manner.

38. All hazardous wastes generated during facility construction and operation must be handled and disposed of in accordance with applicable laws, ordinances, regulations, and standards. Any hazardous wastes generated during construction must be collected in hazardous waste accumulation containers near the point of generation and moved daily to the contractor's 90-day hazardous waste storage area located on-site. The accumulated waste must subsequently be delivered to an authorized waste management facility. Hazardous wastes must be either recycled or managed and disposed of properly in a licensed Class I waste disposal facility authorized to accept the waste.

39. The Discharger shall monitor the evaporation ponds in conformance with applicable CCR Title 27 requirements for Class II surface impoundment waste management units.

40. The leachate collection and removal system must be used to provide preliminary detection monitoring of leaks through the top liner of the doublelined evaporation ponds. Physical evidence of leachate beneath the upper concrete liner shall be interpreted as a warning that containment of the evaporation pond contents may be compromised.

41. Groundwater monitoring wells must be constructed adjacent to and both up gradient and down gradient of the evaporation ponds to provide background and detection monitoring for any potential release from the evaporation ponds containment. The Point of Compliance to be used for the detection monitoring must be the uppermost groundwater beneath the evaporation pond. The groundwater monitoring wells must be constructed in conformance with Title 27 CCR Section 20415 requirements. The monitoring wells must be designed to meet the background and detection monitoring requirements in conformance with Title 27 CCR Section 20415(b)(1)(B) as applicable, including:

    a. Providing a sufficient number of monitoring points to yield ground water samples from the uppermost aquifer that represent the quality of ground water passing the Point of Compliance and to allow for the detection of a release from the evaporation ponds;

    b. Providing a sufficient number of monitoring points and background monitoring points installed at appropriate locations and depths to yield ground water samples from the uppermost aquifer to provide the best assurance of the earliest possible detection of a release from the evaporation ponds; and

    c. Selecting monitoring point locations and depths that include the zone(s) of highest hydraulic conductivity in the ground water body monitored.

42. The detection monitoring wells shall be constructed to meet the well performance standards set forth in Title 27 CCR Section 20415(b)(4), as applicable, including:

43. All monitoring wells shall be cased and constructed in a manner that maintains the integrity of the monitoring well bore hole and prevents the bore hole from acting as a conduit for contaminant transport.

44. The sampling interval of each monitoring well shall be appropriately screened and fitted with an appropriate filter pack to enable collection of representative ground water samples.

45. For each monitoring well, the annular space (i.e., the space between the bore hole and well casing) above and below the sampling interval shall be appropriately sealed to prevent entry of contaminants from the ground surface, entry of contaminants from the unsaturated zone, cross contamination between portions of the zone of saturation, and contamination of samples.

46. All monitoring wells shall be adequately developed to enable collection of representative ground water samples.

47. The monitoring program must also meet the general requirements set forth in Title 27 CCR Section 20415(e), which require that all monitoring systems be designed and certified by a registered geologist or a registered civil engineer. The applicable general requirements set forth for boring logs, quality assurance/quality control, sampling and analytical methods used, background sampling, data analysis, and other reporting as applicable will be implemented.

48. Baseline samples of the groundwater must be collected from each of the monitoring wells and analyzed prior to discharging wastewater to the evaporation ponds. The groundwater must be initially sampled for each of the proposed monitoring parameters listed in the attached Monitoring and Reporting Program, Appendix D, and any additional Constituents of Concern (COC) identified by the Regional Board.

B. Prohibitions

1. The discharge or deposit of solid waste to the evaporation ponds as a final form of disposal is prohibited, unless authorized by the Regional Board's Executive Officer.

2. The Discharger is prohibited from discharging, treating or composting at this site the following wastes:

    a. Municipal solid waste;

    b. Sludge (including sewage sludge, water treatment sludge, and industrial sludge);

    c. Septage;

    d. Liquid waste, unless specifically allowed by these WDRs or approved by the Regional Board's Executive Officer;

    e. Oily and greasy liquid waste; unless specifically allowed by these WDRs or approved by the Regional Board's Executive Officer;

    f. Hot, burning waste materials or ash.

3. The Discharger shall not cause degradation of any groundwater aquifer or water supply.

4. The discharge of waste to land not owned or controlled by the Discharger is prohibited.

5. Use of wastewater or cooling tower liquids on access roads, well pads, or other developed project locations for dust control is prohibited.

6. The discharge of hazardous or designated wastes to other than a waste management unit authorized to receive such waste is prohibited.

7. Any hazardous waste generated or stored at the facility will be contained and disposed in a manner that complies with federal and state regulations.

8. Wastewater or any fluids in the evaporation ponds shall not enter any canal, drainage, or drains (including subsurface drainage systems) which could provide flow to the Waters of the State.

9. The Discharger shall appropriately dispose of any materials, including fluids and sediments removed from the evaporation ponds.

10. The Discharger shall neither cause nor contribute to the contamination or pollution of ground water via the release of waste constituents in either liquid or gaseous phase.

11. Direct or indirect discharge of any waste to any surface water or surface drainage courses is prohibited.

12. The Discharger shall not cause the concentration of any Constituent of Concern or Monitoring Parameter to exceed its respective background value in any monitored medium at any Monitoring Point assigned for Detection Monitoring pursuant to the attached Monitoring and Reporting, Appendix D, and future revisions thereto.

C. Provisions

1. The Discharger shall comply with the attached Monitoring and Reporting Program, Appendix D, and future revisions thereto, as specified by the Regional Board's Executive Officer.

2. Unless otherwise approved by Regional Board's Executive Officer, all analyses shall be conducted at a laboratory certified for such analyses by the California Department of Public Health. All analyses shall be conducted in accordance with the latest edition of "Guideline Establishing Test Procedures for Analysis of Pollutants", promulgated by the United States Environmental Protection Agency.

3. The laboratory shall use detection limits less than or equal to Environmental Protection Agency (EPA) Action Level/Maximum Contaminate Levels (MCLs) or California Department of Public Health (CDPH) Notification Level/MCL for all samples analyzed. The lowest concentration, whether EPA or CDPH, of the two agencies must be used for the analysis.

4. Prior to any change in ownership of this operation, the Discharger shall transmit a copy of the Board Order to the succeeding owner/operator, and forward a copy of the transmittal letter to the Regional Board.

5. Prior to any modification in this facility that would result in material change in the quality or quantity of discharge, or any material change in the location of discharge, the Discharger shall report all pertinent information in writing to the Regional Board's Executive Officer and obtain revised waste discharge requirements before any modification is implemented.

6. All permanent containment structures and erosion and drainage control systems shall be certified by a California Registered Civil Engineer or Certified Engineering Geologist as meeting the prescriptive standards and performance goals.

7. The Discharger shall ensure that all site-operating personnel are familiar with the content of these WDRs, and shall maintain a copy of these WDRs at the site.

8. These WDRs do not authorize violation of any federal, state, or local laws or regulations.

9. The Discharger shall allow the Regional Board, or an authorized representative, upon presentation of credential and other documents as may be required by law, to:

   a. Enter upon the premises regulated by these WDRs, or the place where records must be kept under the conditions of these WDRs;

   b. Have access to and copy, at reasonable times, any records that shall be kept under the condition of these WDRs;

   c. Inspect at reasonable times any facilities, equipment (including monitoring and control equipment), practices, or operations regulated or required under these WDRs; and

   d. Sample or monitor at reasonable times, for the purpose of assuring compliance with these WDRs or as otherwise authorized by the CWC or California Code of Regulations, any substances or parameters at this location.

10. The Discharger shall comply with all of the conditions of these WDRs. Any noncompliance with these WDRs constitutes a violation of the Porter-Cologne Water Quality Act and may be grounds for enforcement action.

11. The Discharger shall at all times properly operate and maintain all facilities and systems of treatment and control (and related appurtenances) that are installed or used by the Discharger to achieve compliance with these WDRs. Proper operation and maintenance also includes adequate laboratory controls and appropriate quality assurance procedures.

12. These WDRs do not convey any property rights of any sort or any exclusive privileges, nor does it authorize any injury to private property or any invasion of personal rights, nor any infringement of federal, state, or local laws or regulations.

13. The Discharger shall comply with the following:

    a. Samples and measurements taken for the purpose of monitoring shall be representative of the monitored activity.

    b. The Discharger shall retain records of all monitoring information, copies of all reports required by these WDRs, and records of all data used to complete the application for these WDRs, for a period of at least five (5) years from the date of the sample, measurement, report or application. This period may be extended by request of the Regional Board's Executive Officer at any time.

    c. Records of monitoring information shall include:

        i. The date, exact places, and time of sampling or measurements.

        ii. The individual(s) who performed the sampling or measurements.

        iii. The date(s) analyses were performed.

        iv. The individual(s) responsible for reviewing the analyses.

        v. The results of such analyses.

    d. Monitoring must be conducted according to test procedures described in the attached Monitoring and Reporting Program, Appendix D, unless other test procedures have been specified in these WDRs or approved by the Regional Board's Executive Officer.

14. All monitoring systems shall be readily accessible for sampling and inspection.

15. The Discharger is the responsible party for the WDRs, and the monitoring and reporting program for the Facility. The Discharger shall comply with all conditions of these WDRs. Violations may result in enforcement actions, requiring corrective action or imposing civil monetary liability.

16. The Discharger shall furnish, under penalty of perjury, technical monitoring program reports, and such reports shall be submitted in accordance with the specifications prepared by the Regional Board's Executive Officer. Such specifications are subject to periodic revisions as may be warranted.

17. The Discharger may be required to submit technical reports as directed by the Regional Board's Executive Officer.

18. The procedure for preparing samples for the analyses shall be consistent with the attached Monitoring and Reporting Program, Appendix D, and any future revisions thereto. The Monitoring Reports shall be certified to be true and correct, and signed, under penalty of perjury, by an authorized official of the company. All technical reports require the signature of a California Registered Professional Engineer or Professional Geologist.

19. All monitoring shall be done as described in Title 27 of the CCRs.

SOIL AND WATER RESOURCES – APPENDIX D

MONITORING AND REPORTING PROGRAM FOR WASTEWATER DISCHARGE - Palen Solar Holdings, LLC, Owner/Operator, Palen Solar Electric Generating System, Riverside County

PART I – GENERAL REQUIREMENTS

A. GENERAL

A Discharger who owns or operates a Class II Surface Impoundment is required to comply with the provisions of Title 27, Division 2, Chapter 3, Subchapter 3, Article 1 of the California Code of Regulations for the purpose of detecting, characterizing, and responding to releases to the groundwater. Section 13267, California Water Code (CWC) gives the Colorado River Basin Regional Water Quality Control Board (Regional Board) authority to require monitoring program reports for discharges that could affect the quality of waters within its region.

1. This Monitoring and Reporting Program (MRP) is Appendix D of the WDRs set forth in Appendices B and C, and are incorporated herein by this reference. The principal purpose of this self-monitoring program is:
   a. To document compliance with Waste Discharge Requirements (WDRs), and prohibitions established by the Regional Board;
   b. To facilitate self-policing by the Discharger in the prevention and abatement of pollution arising from waste discharge;
   c. To conduct water quality analyses.
2. The Regional Board Executive Officer may alter the monitoring parameters, monitoring locations, and/or the monitoring frequency during the course of this monitoring program.

B. DEFINITION OF TERMS

1. Affected Persons – all persons who either own or occupy land outside the boundaries of the parcel upon which a waste management unit (surface impoundment or impoundment) is located that has been or may be affected by the release of waste constituents from the unit.
2. Background Monitoring Point – a device (e.g. well) or location (e.g. a specific point along a lakeshore) that is up gradient or side gradient from the impoundment assigned by this MRP, where water quality samples are taken that are not affected by a release from the impoundment and that are used as a basis of comparison against samples taken from down gradient Monitoring Points.
3. Constituents of Concern (COCs) – those constituents likely to be in the waste, or derived from waste constituents in the event of a release from the impoundment.
4. Matrix Effect – refers to any change in the Method Detection Limit (MDL) or Practical Quantitation Limit (PQL) for a given constituent as a result of the

presence of other constituents - either of natural origin or introduced through a spill or release - that are present in the sample being analyzed.

5. Method Detection Limit (MDL) – the lowest constituent concentration that can support a non-zero analytical result with 99 percent reliability. The MDL is laboratory specific and should reflect the detection capabilities of specific procedures and equipment used by the laboratory.

6. Monitored Media – water - bearing media monitored pursuant to this Monitoring and Reporting Program. The Monitored Media may include: (1) groundwater in the uppermost aquifer, in any other portion of the zone of saturation (as defined in Title 27, Section 20164) in which it would be reasonable to anticipate that waste constituents migrating from the surface impoundment could be detected, and in any perched zones underlying the impoundment, (2) any bodies of surface water that could be measurably affected by a release, (3) soil-pore liquid beneath and/or adjacent to the surface impoundment, and (4) soil-pore gas beneath and/or adjacent to the surface impoundment.

7. Monitoring Parameters – the list of constituents and parameters used for the majority of monitoring activity.

8. Monitoring Point – a device (e.g. well) or location (e.g. a specific point along a lakeshore) that is down gradient from the surface impoundment assigned by this MRP, at which samples are collected for the purpose of detecting a release by comparison with samples collected at Background Monitoring Points.

9. Practical Quantification Limit (PQL) – the lowest constituent concentration at which a numerical concentration can be assigned with a 99 percent certainty that its value is within 10 percent of the actual concentration in the sample. The PQL is laboratory specific and should reflect the detection capabilities of specific procedures and equipment used by the laboratory.

10. Reporting Period – the duration separating the submittal of a given type of monitoring report from the time the next iteration of that report is scheduled for submittal. Unless otherwise stated, the due date for any given report shall be 30 days after the end of its Reporting Period.

11. Sample Locations -

    a. For Monitoring Points – the number of data points obtained from a given Monitoring Point during a given Reporting Period – used for carrying out the statistical or non-statistical analysis of a given analyte during a given Reporting Period.

    b. For Background Monitoring Points – the number of new and existing data points from all applicable Background Monitoring Points in a given Monitored Medium – used to collectively represent the background concentration and variability of a given analyte in carrying out a statistical or non-statistical analysis of that analyte during a given Reporting Period.

12. Uppermost Aquifer – the geologic formation nearest the natural ground surface that is an aquifer, as well as, lower aquifers that are hydraulically interconnected with this aquifer within the facility's property boundary.

13. Volatile Organic Constituents (VOCs) – the suite of organic constituents having a high vapor pressure. The term includes at least the 47 organic constituents listed in Appendix I to 40 CFR Part 258.

14. VOC_{water} – the composite monitoring parameter that includes all VOCs that are detectable in less than 10 percent of the applicable background samples. This parameter is analyzed using the non-statistical method described in Part III.A.2 of this MRP, to identify releases of VOCs that are detected too infrequently in background water to allow for statistical analysis.

C. SAMPLING AND ANALYTICAL METHODS

Sample collection, storage, and analysis shall be performed according to the most recent version of Standard USEPA methods, and California ELAP rulings. Water and waste analysis shall be performed by a laboratory approved for these analyses by the California Department of Public Health. Specific methods of analysis must be identified. If methods other than USEPA-approved methods or Standard Methods are used, the exact methodology must be submitted for review and approval by the Regional Board Executive Officer prior to use. The director of the laboratory whose name appears on the certification shall supervise all analytical work in his/her laboratory and shall sign all reports of such work submitted to the Regional Board. All monitoring instruments and equipment shall be properly calibrated and maintained to ensure accuracy of measurement. In addition, the Discharger is responsible for verifying that laboratory analysis of all samples from Monitoring Points and Background Monitoring Points meet the following restrictions:

1. Methods, analysis, and detection limits used must be appropriate for expected concentrations. For detection monitoring of any constituent or parameter found in concentrations that produce more than 90% non-numerical determinations (i.e. "trace" or "ND") in data from Background Monitoring Points for that medium, the analytical methods having the lowest "facility-specific method detection limit (MDL)", defined in Part I.B.5., shall be selected from among those methods that provide valid results in light of any "Matrix Effects" (defined in Part I.B.4.) involved.

2. Analytical results falling between the MDL and the PQL shall be reported as "trace", and shall be accompanied both by the estimated MDL and PQL values for that analytical run, and by an estimate of the constituent's concentration.

3. MDLs and PQLs shall be derived by the laboratory for each analytical procedure, according to State of California laboratory accreditation procedures. These MDLs and PQLs shall reflect the detection and quantitation capabilities of the specific equipment used by the lab. If the lab suspects that, due to a change in matrix or other effects, the true detection limit or quantitation limit for a particular analytical run differs significantly from the laboratory-derived MDL/PQL values,

the results shall be flagged accordingly, along with an estimate of the detection limit and quantitation limit actually achieved.

4. All Quality Assurance/Quality Control (QA/QC) data shall be reported, along with the sample results to which it applies, including the method, equipment, and analytical detection limits, the recovery rates, an explanation of any recovery rate that is less than method recovery standards, the results of equipment and method blanks, the results of spiked and surrogate samples, the frequency of quality control analysis, and the name and qualifications of the person(s) performing the analyses. Sample results shall be reported unadjusted for blank results or spike recovery.

5. Upon receiving written approval from the Regional Board Executive Officer, an alternative statistical or non-statistical procedure can be used for determining the significance of analytical results for a constituent that is a common laboratory contaminant (i.e., methylene chloride, acetone, diethylhexyl phthalate, and di-n-octyl phthalate) during any given Reporting Period in which QA/QC samples show evidence of laboratory contamination for that constituent. Nevertheless, analytical results involving detection of these analytes in any background or down gradient sample shall be reported and flagged for easy reference by Regional Board staff.

6. In cases where contaminants are detected in QA/QC samples (i.e. field, trip, or lab blanks), the accompanying sample results shall be appropriately flagged.

7. The MDL shall always be calculated such that it represents a concentration associated with a 99% reliability of a non-zero result.

D. RECORDS TO BE MAINTAINED

Written reports shall be maintained by the Discharger or laboratory, and shall be retained for a minimum of five (5) years. This period of retention shall be extended during the course of any unresolved litigation regarding this discharge or when requested by the Regional Board. Such records shall show the following for each sample:

1. Identity of sample and of the Monitoring Point or Background Monitoring Point from which it was taken, along with the identity of the individual who obtained the sample;

2. Date and time of sampling;

3. Date and time that analyses were started and completed, and the initials of the personnel performing each analysis;

4. Complete procedure used, including method of preserving the sample, and the identity and volumes of reagents used;

5. Calculations of results; and

6. Results of analyses, and the MDL and PQL for each analysis.

E. REPORTS TO BE FILED WITH THE REGIONAL BOARD

1. Detection Monitoring Reports – For each Monitored Medium, all Monitoring Points and Background Monitoring Points assigned to detection monitoring under Part II.A.7 of this MRP shall be monitored **semiannually** for the Monitoring Parameters (Part II.A.4). A "Detection Monitoring Report" shall be submitted to the Regional Board in accordance with the schedule contained in the Summary of Self-Monitoring and Reporting Requirements, and shall include the following:

    a. A Letter of Transmittal that summarizes the essential points in each report shall accompany each report submittal. The letter of transmittal shall be signed by a principal executive officer at the level of vice-president or above, or by his/her duly authorized representative, if such representative is responsible for the overall operation of the facility from which the discharge originates. The letter of transmittal shall include:

        i. A discussion of any violations noted since the previous report submittal and a description of the actions taken or planned for correcting those violations. If no violations have occurred since the last submittal, that should be so stated;

        ii. If the Discharger has previously submitted a detailed time schedule or plan for correcting any violations, a progress report on the time schedule and status of the corrective actions being taken; and

        iii. A statement by the official, under penalty of perjury, that to the best of the signer's knowledge the report is true, complete, and correct.

    b. A Compliance Evaluation Summary shall be included in each Detection Monitoring Report. The compliance evaluation summary shall contain at least:

        i. Velocity and direction of groundwater flow for each monitored groundwater body under and around the surface impoundment based upon the water level elevations taken during the collection of water quality data. A description and graphical presentation (e.g., arrow on a map) shall be submitted;

        ii. Methods used for water level measurement and pre-sampling purging for each monitoring well addressed by the report including:

            1. Method, time, and equipment used for water level measurement;

            2. Type of pump used for purging, placement of the pump in the well, pumping rate, and well recovery rate;

            3. Methods and results of field testing for pH, temperature, electrical conductivity, and turbidity, including;

                a. Equipment calibration methods, and

                b. Method for disposing of purge water

iii. Methods used for sampling each Monitoring Point and Background Monitoring Point, including:

1. A description of the type of pump, or other device used, and its placement for sampling;

2. A detailed description of the sampling procedure: number and description of samples, field blanks, travel blanks, and duplicate samples; types of containers and preservatives used; date and time of sampling; name and qualifications of individual collecting samples, and other relevant observations;

c. A map or aerial photograph showing the locations of Monitoring Points, and Background Monitoring Points;

d. For each Detection Monitoring Report, provide all relevant laboratory information including results of all analyses, and other information needed to demonstrate compliance with Part I.C.;

e. An evaluation of the effectiveness of the run-off/run-on control facilities;

f. A summary of reportable spills/leaks occurring during the reporting period; include estimated volume of liquids/solids discharged outside designated containment area, a description of management practices to address spills/leaks, and actions taken to prevent reoccurrence.

2. Annual Summary Report – The Discharger shall submit to the Regional Board, an "Annual Summary Report" for the period extending from January 1 through December 31. The "Annual Summary Report" is due **March 15** of each year, and shall include the following:

a. A graphical presentation of analytical data for each Monitoring Point and Background Monitoring Point (Title 27, Section 20415(e)(14)). The Discharger shall submit, in graphical format, the laboratory analytical data for all samples taken within at least the previous five (5) calendar years. Each such graph shall plot the concentration of one (1) or more constituents over time for a given Monitoring Point and Background Monitoring Point, at a scale appropriate to show trends or variations in water quality. The graphs shall plot each datum, rather than plotting mean values. For any given constituent or parameter, the scale for background plots shall be the same as that used to plot down gradient data. On the basis of any aberrations noted in the plotted data, the Regional Board Executive Officer may direct the Discharger to carry out a preliminary investigation (Title 27, Section 20080(d)(2)), the results of which will determine whether or not a release is indicated;

b. A tabular presentation of all monitoring analytical data obtained during the previous two (2) Monitoring and Reporting Periods, submitted on hard copy within the annual report as well as digitally on electronic media in a file format acceptable to the Regional Board Executive Officer (Title 27, Section 20420(h)). The Regional Board regards the submittal of data in hard copy and on diskette CD-ROM as "...a form necessary for..." statistical analysis in that this facilitates periodic review by the Regional Board statistical consultant;

c. A comprehensive discussion of the compliance record and any corrective actions taken or planned, which may be needed to bring the Discharger into full compliance with WDRs;

d. A written summary of the groundwater analyses, indicating changes made since the previous annual report; and

e. An evaluation of the effectiveness of the run on/run-off control facilities, pursuant to Title 27, Section 20365.

3. <u>Contingency Reporting</u>

a. The Discharger shall report any spill of evaporation pond liquid by telephone within 48 hours of discovery. The reportable quantity for evaporation pond liquid is 150 gallons.

After reporting a spill, a written report shall be filed with the Regional Board Executive Officer within seven (7) days, containing at a minimum the following:

i. A map showing the location(s) of the discharge/spill;

ii. A description of the nature of the discharge (all pertinent observations and analyses including quantity, duration, etc.); and

iii. Corrective measures underway or proposed.

b. Should the initial statistical comparison (Part III.A.1.) or non-statistical comparison (Part III.A.2.) indicate, for any Constituent of Concern or Monitoring Parameter, that a release is tentatively identified, the Discharger shall immediately notify the Regional Board verbally as to the Monitoring Point(s) and constituent(s) or parameter(s) involved, shall provide written notification by certified mail within seven (7) days of such determination (Title 27, Section 20420(j)(1)), and shall conduct a discrete retest in accordance with Part III.A.3. If the retest confirms the existence of a release, the Discharger shall carry out the requirements of Part I.E.3.d. In any case, the Discharger shall inform the Regional Board of the outcome of the retest as soon as the results are available, following up with written results submitted by certified mail within seven (7) days of completing the retest.

c. If either the Discharger or the Regional Board determines that there is significant physical evidence of a release (Title 27, Section 20385(a)(3)), the Discharger shall immediately notify the Regional Board of this fact by certified mail (or acknowledge the Regional Board's determination) and shall carry out the requirements of Part I.E.3.d. for all potentially-affected monitored media.

d. If the Discharger concludes that a release has been discovered:

i. If this conclusion is <u>not</u> based upon “direct monitoring” of the Constituents of Concern, pursuant to Part II.A.5., then the Discharger shall, within thirty days, sample for all Constituents of Concern at all Monitoring Points and submit them for laboratory analysis. Within seven (7) days of receiving the laboratory analytical results, the Discharger shall notify the Regional Board, by certified mail, of the concentration of all Constituents of Concern at each Monitoring Point. Because this scan is not to be tested against background, only a single datum is required for each Constituent of Concern at each Monitoring Point [Title 27 Section 20420(k)(1)];

ii. The Discharger shall, within 90 days of discovering the release (Title 27, Section 20420(k)(5)), submit a Revised Report of Waste Discharge proposing an Evaluation Monitoring Program meeting the requirements of Title 27, Section 20425; and

iii. The Discharger shall, within 180 days of discovering the release (Title 27, Section 20420(k)(6), submit a preliminary engineering feasibility study meeting the requirements of Title 27, Section 20430.

e. Any time the Discharger concludes - or the Regional Board Executive Officer directs the Discharger to conclude - that a liquid phase release from the surface impoundment has proceeded beyond the facility boundary, the Discharger shall so notify all persons who either own or reside upon the land that directly overlies any part of the plume (Affected Persons).

i. Initial notification to Affected Persons shall be accomplished within 14 days of making this conclusion and shall include a description of the Discharger's current knowledge of the nature and extent of the release; and

ii. Subsequent to initial notification, the Discharger shall provide updates to all Affected Persons, including any persons newly affected by a change in the boundary of the release, within 14 days of concluding a material change in the nature or extent of the release has occurred.

4. <u>Surface Impoundment - Leakage Detection System (LDS), and Solids Monitoring</u>

a. Sampling and reporting shall be conducted semi-annually.

b. Provide volume of solids removed from the holding pond each month for that reporting period, and transported to a waste management facility for disposal. Include name and location of waste management facility.

c. Conduct quarterly inspections of Leakage Detection System (LDS), and holding pond.

PART II – MONITORING REQUIREMENTS FOR GROUNDWATER

A. GROUNDWATER SAMPLING AND ANALYSIS FOR DETECTION MONITORING

1. Groundwater Surface Elevation and Field Parameters – Groundwater sampling and analysis shall be conducted semiannually pursuant to California ELAP rulings, and include an accurate determination of the groundwater surface elevation and field parameters (temperature, electrical conductivity, turbidity) for each Monitoring Point and Background Monitoring Point (Title 27, Section 20415(e)(13)). Groundwater elevation obtained prior to purging the well and sample collection, shall be used to fulfill the semi-annual groundwater flow rate/direction analyses required under Part I.E.1.b.i. Groundwater wells shall be gauged using an electronic sounder capable of measuring depth to groundwater within 100th of an inch. Following gauging, wells shall be purged according to EPA groundwater sampling procedures until:

   a. pH, temperature, and conductivity are stabilized within 10 percent, and

   b. turbidity has been reduced to 10 NTUs or the lowest practical levels achievable.

   The above identified parameters shall be recorded in the field, and submitted in the monitoring report. Sampling equipment shall be decontaminated between wells. Purge water may be discharged to the brine pond; discharge to the ground surface is prohibited.

2. Groundwater Sample Collection - Groundwater samples shall be collected from all monitoring points and background monitoring points after wells recharge to within at least 80 percent of their original static water level. Groundwater samples shall be collected with a paristaltic pump that is decontaminated between sampling events. Samples shall be labeled, logged on chain-of-custody forms, and placed in cold storage pending delivery to a State certified analytical laboratory.

3. Five-Day Sample Procurement Limitation – To satisfy data analysis requirements for a given reporting period, samples collected from all Monitoring Points and Background Monitoring Points shall be taken within a span not exceeding five (5) days, and shall be taken in a manner that insures sample independence to the greatest extent feasible (Title 27, Section 20415(e)(12)(B)).

4. Groundwater Monitoring Parameters for Detection Monitoring – Groundwater samples collected from monitoring points and background monitoring points shall be analyzed for the following:

Parameter	Unit	Sample Type
Chloride	mg/L	Grab
Sulfate	mg/L	Grab
Total Dissolved Solids (TDS)	mg/L	Grab

pH	#	Grab
Specific Conductance	μohms/cm	Grab
Heavy Metals (Sb, As, Ba, Cd, Ca, Cr, Co, Cu,		
Pb, Hg, Ni, Se, Zn)	mg/L	Grab
Oil & Grease	mg/L	Grab

All Monitoring Points and Background Monitoring Points assigned to Detection Monitoring shall be sampled semi-annually in **June** and **December** of each year in accordance with Part I of this MRP. Monitoring results shall be reported in the semi-annual Detection Monitoring Report.

5. Data Analysis – Statistical or non-statistical analysis shall be carried out as soon as the data is available, in accordance with Part III of this monitoring program.

   Monitoring Points and Background Monitoring Points – At a minimum of 90 days prior to the operation of the facility, the Discharger shall submit a proposed groundwater monitoring program, including background and detection monitoring locations, to the Executive Officer for review and approval.

6. Initial Background Determination: For the purpose of establishing an initial pool of background data for each Constituent of Concern at each Background Monitoring Point [Title 27, Section 20415(e)(6)]:

   a. Whenever a new Constituent of Concern is added to the Water Quality Protection Standard, including any added by the adoption of this Board Order, the Discharger shall collect at least one (1) sample **quarterly** for at least one (1) year from each Background Monitoring Point in each monitored medium and analyze for the newly-added constituent(s); and

   b. Whenever a new Background Monitoring Point is added, including any added by this Board Order, the Discharger shall sample the new monitoring point at least **quarterly** for at least one (1) year, analyzing for all Constituents of Concern and Monitoring Parameters.

7. Semiannual Determination of Groundwater Flow Rate/Direction (Title 27, Section 20415(e)(15): The Discharger shall measure the water level in each well and determine groundwater flow rate and direction in each groundwater body described in Part II.A.1. at least semiannually. This information shall be included in the semi-annual Detection Monitoring Reports required under Part I.E.1.

PART III – STATISTICAL AND NON-STATISTICAL ANALYSES

A. STATISTICAL AND NON-STATISTICAL ANALYSIS

The Discharger shall use the most appropriate of the following methods to compare the down gradient concentration of each monitored constituent or parameter with its respective background concentration to determine if there has been a release from the surface impoundment. For any given data set, proceed sequentially down the list of statistical analysis methods listed in Part III.A.1., followed by the non-statistical method in Part III.A.2., using the first method for which the data qualifies. If that analysis tentatively indicates the detection of a release, implement the retest procedure under Part III.A.3.

1. Statistical Methods. The Discharger shall use one (1) of the following statistical methods to analyze Constituents of Concern or Monitoring Parameters that exhibit concentrations exceeding their respective MDL in at least ten percent of the background samples taken during that Reporting Period. Each of these statistical methods is more fully described in the Statistical Methods discussion below. Except for pH, which uses a two-tailed approach, the statistical analysis for all constituents and parameters shall be a one-tailed (testing only for statistically significant increase relative to background) approach:

   a. One-Way Parametric Analysis of Variance (ANOVA) followed by multiple comparisons (Title 27, Section 20415(e)(8)) – This method requires at least four (4) independent samples from each Monitoring Point and Background Monitoring Point during each sampling episode. It shall be used when the background data for the parameter or constituent obtained during a given sampling period, has not more than 15% of the data below PQL. Prior to analysis, replace all 'trace' determinations with a value halfway between the PQL and the MDL values reported for that sample run, and replace all "non-detect" determinations with a value equal to half the MDL value reported for that sample run. The ANOVA shall be carried out at the 95% confidence level. Following the ANOVA, the data from each down gradient Monitoring Point shall be tested at a 99% confidence level against the pooled background data. If these multiple comparisons cause the Null Hypothesis (i.e., that there is no release) to be rejected at any Monitoring Point, the Discharger shall conclude that a release is tentatively indicated from that parameter or constituent; or

   b. One-Way Non-Parametric ANOVA (Kruskal-Wallis Test), followed by multiple comparisons – This method requires at least nine (9) independent samples from each Monitoring Point and Background Monitoring Point; therefore, the Discharger shall anticipate the need for taking more than four (4) samples per Monitoring Point, based upon past monitoring results. This method shall be used when the pooled background data for the parameter or constituent, obtained within a given sampling period, has not more than 50% of the data below the PQL. The ANOVA shall be carried out at the 95% confidence level. Following the ANOVA, the data from each down gradient Monitoring Point shall be tested at a 99% confidence level against the pooled background data. If these multiple comparisons cause the Null Hypothesis (i.e., that there is no release) to be rejected at any Monitoring Point, the Discharger shall conclude that a release is tentatively indicated for that parameter or constituent; or

c. Method of Proportions – This method shall be used if the "combined data set" – the data from a given Monitoring Point in combination with the data from the Background Monitoring Points – has between 50% and 90% of the data below the MDL for the constituent or parameter in question. This method; (1) requires at least nine (9) down gradient data points per Monitoring Point per Reporting Period, (2) requires at least thirty data points in the combined data set, and (3) requires that n * P > 5 (where n is the number of data points in the combined data set and P is the proportion of the combined set that exceeds the MDL); therefore, the Discharger shall anticipate the number of samples required, based upon past monitoring results. The test shall be carried out at the 99% confidence level. If the analysis results in rejection of the Null Hypothesis (i.e., that there is no release), the Discharger shall conclude that a release is tentatively indicated for that constituent or parameter; or

d. Other Statistical Methods. – These include methods pursuant to Title 27, Section 20415(e)(8)(c-e).

2. Non-Statistical Method. The Discharger shall use the following non-statistical methods for all constituents that are not amenable to statistical analysis by virtue of having been detected in less than 10% of applicable background samples. A separate variant of this test is used for the VOC_{water} Composite Monitoring Parameters. Regardless of the test variant used, the method involves a two-step process: (1) from all constituents to which the test variant applies, compile a list of those constituents which equal or exceed their respective MDL in the down gradient sample from a given Monitoring Point, then (2) evaluate whether the listed constituents meet either of the test variant's two possible triggering conditions. For each Monitoring Point, the list described above shall be compiled based on either the data from a single sample taken during the Monitoring Period for that Monitoring Point, or (where several independent samples have been analyzed for that constituent at a given Monitoring Point) from the sample that contains the largest number of detected constituents. Background shall be represented by the data from all samples taken from the appropriate Background Monitoring Points during that Reporting Period (at least one (1) sample from each Background Monitoring Point). The method shall be implemented as follows:

a. VOC_{water} Composite Monitoring Parameter – For any given Monitoring Point, the VOC_{water} Monitoring Parameter is a composite parameter addressing all detectable VOCs including at least all 47 VOCs listed in Appendix I to 40 CFR 258 and all unidentified peaks. The Discharger shall compile a list of each VOC which (1) exceeds its MDL in the Monitoring Point sample (an unidentified peak is compared to its presumed (MDL), and also (2) exceeds its MDL in less than ten percent of the samples taken during that Reporting Period from that medium's Background Monitoring Points. The Discharger shall conclude that a release is tentatively indicated for the VOC_{water} composite Monitoring Parameter if the list either (1) contains two or more constituents, or (2) contains one constituent that exceeds its PQL;

b. Constituents of Concern: As part of the COC monitoring required under Part 2.A.5 of this MRP, for each Monitoring Point, the Discharger shall compile a list of COCs that exceed their respective MDL at the Monitoring Point, yet do so in less than ten percent of the background samples taken during that Reporting Period. The Discharger shall conclude that a release is tentatively indicated if the list either (1) contains two or more constituents, or (2) contains one constituent that exceeds its PQL.

3. Discrete Retest – In the event that the Discharger concludes that a release has been tentatively indicated (under Parts III.A.1. or III.A.2.), the Discharger shall, within 30 days of that conclusion, collect two (2) new suites of samples for the indicated Constituent(s) of Concern or Monitoring Parameter(s) at each indicated Monitoring Point, collecting at least as many samples per suite as were used for the initial test. Re-sampling of Background Monitoring Points is optional. As soon as the retest data is available, the Discharger shall use the same statistical method or non-statistical comparison separately on each suite of retest data. For any indicated Monitoring Parameter or Constituent of Concern at an affected Monitoring Point, if the test results of either (or both) of the retest data suites confirms the original indication, the Discharger shall conclude that a release has been discovered. All retests shall be carried out only for the Monitoring Point(s) for which a release is tentatively indicated, and only for the Constituent of Concern or Monitoring Parameter that triggered the indication there, as follows:

   a. If an ANOVA method was used in the initial test, the retest shall involve only a repeat of the multiple comparison procedure, carried out separately on each of the two (2) new suites of samples taken from the indicating Monitoring Point;

   b. If the Method of Proportions statistical test was used, the retest shall consist of a full repeat of the statistical test for the indicated constituent or parameter, carried out separately on each of the two (2) new sample suites from the indicating Monitoring Point;

   c. If the non-statistical comparison was used:

      i. Because the VOC Composite Monitoring parameters (VOC_{water}) each address, as a single parameter, an entire family of constituents which are likely to be present in any surface impoundment release, the scope of the laboratory analysis for each retest sample shall include all VOCs detectable in that retest sample. Therefore, a confirming retest for either parameter shall have validated the original indication even if the suite of constituents in the confirming retest sample(s) differs from that in the sample that initiated the retest;

      ii. Because all Constituents of Concern that are jointly addressed in the non-statistical testing under Part III.A.2. remain as individual Constituents of Concern, the scope of the laboratory analysis for the non-statistical retest samples shall be narrowed to involve only those constituents detected in the sample which initiated the retest.

SUMMARY OF SELF-MONITORING AND REPORTING REQUIREMENTS

A. GROUNDWATER MONITORING

1. Groundwater monitoring wells shall be sampled/analyzed semi-annually for the following parameters/constituents:

Parameters &	Type of	Reporting	
Constituent	**Unit**	**Sample**	**Frequency**
a. Chloride	mg/L	grab	semiannual
b. Sulfate	mg/L	grab	semiannual
Total Dissolved Solids (TDS)	mg/L	grab	semiannual
c. PH	#	field measurement	semiannual
d. Specific Conductance	μohms/cm	field measurement	semiannual
e. Heavy Metals (Sb,As, Ba, Cd, Ca, Cr, Co, Cu, Pb, Hg, Ni, Se, Zn)	mg/L	grab	semiannual
f. Oil & Grease	mg/L	grab	semiannual

2. The collection, preservation, and holding times of all samples shall be in accordance with the U.S. Environmental Protection Agency approved procedures. All analyses shall be conducted by a laboratory certified by the California Department of Public Health to perform the required analyses.

B. SURFACE IMPOUNDMENT: Leakage Detection System (LDS), and Solids Monitoring

	Unit	Observation or Sampling Frequency	Reporting Frequency
1. Estimated volume of solid/liquid in holding pond	ft^3	Monthly	semiannual
2. Measurement of freeboard	ft	Monthly	semiannual
3. Volume of solids removed and shipped to off-site waste management facility	tons	Monthly	semiannual

C. MONITORING REPORTS AND OBSERVATION SCHEDULE

"Reporting Period" means the duration separating the submittal of a given type of monitoring report from the time the next iteration of that report is scheduled for submittal. An annual report, which is a summary of all the monitoring during the previous year, shall also be submitted to the Regional Board. The submittal dates for Detection Monitoring Reports and the Annual Summary Report are as follows:

1. Detection Monitoring Reports
   a. 1st Semiannual Report (January 1 through June 30) – report due by **August 1**
   b. 2nd Semiannual Report (July 1 through December 31) – report due by **March 1**
2. Annual Summary Report

   January 1 through December 31 – report due **March 15** of the following year.
3. The Detection Monitoring Reports and the Annual Summary Report shall include the following:
   a. The Discharger shall arrange the data in tabular form so that the specified information is readily discernible. The data shall be summarized in such a manner as to clearly illustrate whether the facility is operating in compliance with WDRs.
   b. Records of monitoring information shall include:
      i. The date, exact place, and time of sampling or measurement;
      ii. The individual performing the sampling or measurement;
      iii. The date the analysis was performed;
      iv. The initials of the individual performing the analysis;
      v. The analytical technique or method used; and
      vi. The result of the analysis.
   c. Each report shall contain the following statement:

      "I declare under the penalty of law that I have personally examined and am familiar with the information submitted in this document, and that based on my inquiry of those individuals immediately responsible for obtaining the information, I believe that the information is true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of a fine and imprisonment for knowing violations."
   d. A duly authorized representative of the Discharger may sign the documents if:
      i. Authorization is made in writing by the person described in Part I.E.1.a;

ii. Authorization specifies an individual or person having responsibility for the overall operation of the regulated disposal system; and

iii. Written authorization is submitted to the Regional Board Executive Officer.

iv. Monitoring reports shall be certified under penalty of perjury to be true and correct, and shall contain the required information at the frequency designated in this monitoring report. All technical reports require the signature of a California Registered Professional Engineer or Professional Geologist.

TRAFFIC AND TRANSPORTATION

Testimony of Andrea Koch, Gregg Irvin, Ph.D., Alvin Greenberg, Ph.D., and David Flores

SUMMARY OF CONCLUSIONS

California Energy Commission (Energy Commission) staff has analyzed the information provided in the Petition for Amendment and acquired from other sources to determine the potential for the Palen Solar Electric Generating System (PSEGS) project to have significant traffic and transportation-related impacts. Staff has also assessed the potential for mitigation proposed by the project owner and conditions developed by staff to reduce any potential impacts to a less than significant level, as well as the feasibility and enforceability of those proposed mitigations and recommended conditions of certification.

Without mitigation, peak construction of the PSEGS would cause significant impacts to traffic level of service (LOS) on Corn Springs Road and, during the morning peak hour, at the Corn Springs Road and Interstate 10 (I-10) ramp intersections. Implementation of proposed Condition of Certification **TRANS-1**, which would require preparation and implementation of a traffic control plan, would mitigate these traffic impacts to less than significant. PSEGS operations traffic would cause less than significant impacts to traffic LOS that would require no mitigation.

There is no risk for either photothermal or photochemical retinal damage to motorists, pilots or the general civilian population outside of the PSEGS site from either the heliostats or solar power tower solar receiver steam generators (SRSGs). However, without mitigation, direct solar reflections from the heliostats (DSRH) would cause drivers on I-10 to experience discomfort glint and glare, and potentially disability glint and glare. Implementation of proposed Condition of Certification **TRANS-7** requires a Heliostat Positioning and Monitoring Plan that would minimize the frequency of DSRH events during the testing, calibration and operational phases of the PSEGS, resulting in less than significant impacts to motorists and pilots.

Sustained glare from the SRSGs during nominal operating conditions (where luminance would be less than $1x10^6$ candelas per meter squared [cd/m^2]) would not produce discomfort or disability glare that would interfere with motorists' or pilots' abilities to operate their vehicles and planes, respectively. However, at higher luminance levels, the SRSGs could produce discomfort or disability glare that would significantly impact drivers on I-10. To ensure that the SRSGs operate at acceptable luminance levels that would not impact the traveling public, staff has proposed Condition of Certification **TRANS-8** to require a solar power tower receiver luminance and monitoring plan. **TRANS-8** would provide procedures for identification and mitigation of visual distraction, discomfort glare, or disability glare effects with the potential of causing significant impacts to motorists.

INTRODUCTION

In the Traffic and Transportation analysis, Energy Commission staff focuses on (1) whether construction and operation of the Palen Solar Electric Generating System (PSEGS) would result in significant traffic and transportation impacts under the California Environmental Quality Act (CEQA); and (2) whether the project would comply with applicable laws, ordinances, regulations, and standards (LORS). The analysis includes discussion of potential impacts to surrounding transportation systems and roadways resulting from construction and operation of the PSEGS. Energy Commission staff proposes mitigation measures (conditions of certification) where necessary.

METHODOLOGY AND THRESHOLDS FOR DETERMINING ENVIRONMENTAL CONSEQUENCES

Significance criteria used in this document for evaluating environmental impacts are based on the CEQA Guidelines, the CEQA Environmental Checklist for Transportation/Traffic, performance standards or thresholds identified by Energy Commission staff, and applicable LORS used by other governmental agencies. Specifically, staff analyzed whether the proposed project would:

1. cause an increase in traffic that is substantial in relation to the existing traffic load and capacity of the street system (i.e., result in a substantial increase in either the number of vehicle trips, the volume-to-capacity ratio on roads, or congestion at intersections);

2. conflict with an applicable plan, ordinance or policy establishing measures of effectiveness for the performance of the circulation system, taking into account all modes of transportation including mass transit and non-motorized travel and relevant components of the circulation system, including but not limited to intersections, streets, highways and freeways, pedestrian and bicycle paths, and mass transit;

3. conflict with an applicable congestion management program, including, but not limited to, level of service (LOS) standards and travel demand measures, or other standards established by the county congestion management agency for designated roads or highways;

4. substantially increase hazards due to a design feature (e.g., sharp curves, dangerous intersections, or glint and glare) or incompatible uses (e.g., farm equipment);

5. result in inadequate emergency access;

6. conflict with adopted policies, plans, or programs regarding public transit, bicycle, or pedestrian facilities, or otherwise decrease the performance or safety of such facilities;

7. result in a change in air traffic patterns, including either an increase in traffic levels or a change in location that results in substantial safety risks;

8. produce a thermal plume in an area where flight paths are expected to occur below 1,000 feet from the ground[1]; or

9. have individual environmental effects that, when considered with other impacts from the same project or in conjunction with impacts from other closely related past, present, and reasonably foreseeable future projects, are considerable or compound or increase other environmental impacts.

LAWS, ORDINANCES, REGULATIONS, AND STANDARDS (LORS)

In addition to the LOS significance criteria discussed above in "Methodology and Thresholds for Determining Environmental Consequences", staff uses laws, ordinances, regulations, and standards (LORS) as significance criteria to determine if the proposed PSEGS would have a significant adverse impact on the environment. The federal, state, and local LORS that are applicable to the proposed PSEGS are listed below in **Traffic and Transportation – Table 1**:

Traffic and Transportation – Table 1
Laws, Ordinances, Regulations, and Standards (LORS)

Applicable LORS	Description
Federal	
Title 14, Code of Federal Regulations, Aeronautics and Space, part 77 - Objects Affecting Navigable Airspace (14 C.F.R. part 77)	These regulations establish standards for determining physical obstructions to navigable airspace; set noticing and hearing requirements; provide for aeronautical studies to determine the effect of physical obstructions on the safe and efficient use of airspace; and oversee the development of antenna farm areas.
Title 49, Code of Federal Regulations Subtitle B, parts 171-173, 177-178, 350-359, 397.9 and Appendices A-G	Addresses safety considerations for the transport of goods, materials, and substances. Governs the transportation of hazardous materials including types of materials and marking of the transportation vehicles.
State	
California Vehicle Code, sections 353; 2500-2505; 31303-31309; 32000-32053; 32100-32109; 31600-31620; California Health and Safety Code, sections 25160 et seq.	Regulates the highway transport of hazardous materials.
California Vehicle Code, sections 13369; 15275 and 15278	Addresses the licensing of drivers and the classification of licenses required for the operation of particular types of vehicles; also requires certificates permitting operation of vehicles transporting hazardous materials.
California Vehicle Code, sections 35100 et seq.; 35250 et seq.; 35400 et seq.	Specifies limits for vehicle width, height, and length.
California Vehicle Code, section 35780	Requires permits for any load exceeding Caltrans weight, length, or width standards on public roadways.
California Streets and Highways Code, sections 117, 660-672	Requires permits for any load exceeding Caltrans weight, length, or width standards on County roads.

[1] The FAA recommends that pilots avoid overflight of plume-generating industrial sites below 1,000 feet AGL (FAA 2006).

Applicable LORS	Description
California Streets and Highways Code, sections 117, 660-670, 1450, 1460 et seq., and 1480 et seq.	Regulates permits from Caltrans for any roadway encroachment from facilities that require construction, maintenance, or repairs on or across State highways and County roads.
Local	
Riverside County General Plan Circulation Element	Specifies long-term planning goals and procedures for transportation infrastructure system quality.
Riverside County General Plan Circulation Element	Specifies LOS standards used to assess the performance of a street or highway system and the capacity of a roadway.
Riverside County Municipal Code Title 10, Chapter 10.08, Sections 10.08.010-10.08.180	Specifies limits and permit requirements for oversize loads.
Riverside County Municipal Code Title 12, Chapter 12.08, Sections 12.08.010-12.08.100	Specifies requirements for encroachment permits.

PROPOSED MODIFIED PROJECT

The modified project would use BrightSource's solar power tower technology instead of the originally proposed parabolic trough solar collection system and associated heat transfer fluid. The modified project would consist of two solar fields, designated as Unit 1 and Unit 2, each comprised of 85,000 heliostats (elevated mirrors guided by a tracking system mounted on a pylon) and a 760-foot-high[2] tower. To produce electricity, the heliostats would focus the sun's rays on a solar receiver steam generator located atop each tower, creating steam to drive a turbine that would generate electricity. Each solar field would produce 250 MW of electricity for a combined nominal output of approximately 500 MW.

The two solar fields would share common facilities, including a common area containing an administration building, warehouse, evaporation ponds, maintenance complex, a meter/valve station for incoming natural gas service to the site, an on-site switchyard, and a 10-mile single-circuit 230-kV generation tie-line to deliver power to the newly constructed Red Bluff Substation immediately south of I-10. Other on-site facilities would include access and maintenance roads (either dirt, gravel, or paved), perimeter fencing, tortoise fencing, and other ancillary security facilities. During project construction, there would be an approximately 203-acre laydown area located in the southwestern portion of the site. This area would be used for laydown of materials, parking, staging of traffic to avoid congestion at the I-10/Corn Springs interchange, and possibly a temporary concrete batch plant.

As with the original project, site access would be from Corn Springs Road at the I-10 interchange. Corn Springs Road currently runs north-south across I-10 and terminates just north of the I-10 overpass. From this dead-end, a new 1,350 foot-long access road running east to the project site entrance would be constructed. The new access road would have a paved width of 24 feet and a 12-foot-wide gravel shoulder for truck staging.

[2] The actual tower height would be 750 feet. However, including the lighting appurtenance affixed to the top, the total height of the tower would be 760 feet.

If approved, the units would be constructed in phases, with the first phase of construction including the generation tie-line and Unit 1 and the second phase including Unit 2. The first phase of construction is scheduled to begin in the fourth quarter of 2013, according to the Petition to Amend. However, construction likely would not begin until spring 2014 to allow for desert tortoises to be cleared from the site. The second phase of construction would begin several months later. Commercial operation of both units would likely begin in late 2016, due to the delay for desert tortoise clearing.

SETTING AND EXISTING CONDITIONS

The proposed PSEGS site is located in eastern Riverside County about 10 miles east of the unincorporated community of Desert Center, 3 miles east of the southeastern end of Joshua Tree National Park, and about 0.5 mile north of U.S. Interstate 10. The site is located on approximately 3,794 acres of public land managed by the Bureau of Land Management (BLM) (Right-of-Way No. CACA-048810). See **Traffic and Transportation Figures 1 and 2** for views of the regional and local transportation network in the project vicinity.

LOCAL HIGHWAYS AND ROADS

The following describes the roadways in the vicinity of the PSEGS site:

U.S. Interstate 10

Interstate 10 is an east-west regional arterial that crosses much of the southern United States. It runs from the L.A. area east to Phoenix, Arizona, where it turns south and continues to Tucson, Arizona, ultimately continuing east to Jacksonville, Florida. In the project area, the speed limit is 70 miles per hour and the road is fully improved to freeway status with two lanes in each direction. There are no bicycle or pedestrian facilities located on I-10 near the project site; however, bicycles are allowed on I-10 from Dillon Road, Coachella (west of the PSEGS site) to Mesa Drive, Blythe (east of the PSEGS site). The California Department of Transportation (Caltrans) allows bicycle use on state highways where no alternative route is available.

Corn Springs Road

Corn Springs Road is an exit off of I-10 accessed by a diamond-configured interchange. The interchange includes single-lane ramps with ramp junctures, where stop signs control traffic from I-10 before it enters Corn Springs Road. Corn Springs Road is a relatively short road that runs north toward the project site, as well as south, where it intersects with Chuckwalla Valley Road. Corn Springs Road has a curb and gutter, but no bicycle or pedestrian facilities.

Chuckwalla Valley Road

Chuckwalla Valley Road is a minor local access road running in an east-west direction just south of I-10 in the vicinity of the project site. It is a two-lane frontage road extending from the southern part of the Corn Springs Road interchange to the Ford Dry Lake Road interchange approximately 10 miles to the east. Stop signs on the Chuckwalla Valley Road approaches control the Corn Springs Road/Chuckwalla Valley

Road intersection. Chuckwalla Valley Road has curb and gutter, but no bicycle or pedestrian facilities.

PUBLIC TRANSPORTATION

Public transportation in the project area consists of rail and bus service, bicycle and pedestrian facilities, and airports. Information about these forms of public transportation follows.

Rail and Bus Service

The nearest passenger rail service is an Amtrak station in Palm Springs to the west. With regard to freight rail, on January 13, 2010, the Surface Transportation Board ruled that the Arizona & California Railroad Company could abandon service in Riverside County. Therefore, no rail service exists in the area.

The nearest national bus service stations are the Indio and Blythe Greyhound stations. Local bus service near the project site is limited to the Red Route of the Desert Roadrunner bus service for Blythe, which provides service to the Ironwood/Chuckwalla Valley State Prison approximately 21 miles east of the project, and the Sunline Transit Agency, which provides bus service in the vicinity of Indio.

Bicycle and Pedestrian Facilities

Bicycle and pedestrian activity in the vicinity of the PSEGS site is minimal-to-none. Development is extremely low-density and spread over a large area, which is not conducive to biking or walking.

Aviation Activities

The nearest airport is the Desert Center Airport, located approximately 6 miles northwest of the PSEGS site. It is a private airport with a pattern altitude of 1,559 feet above mean sea level (AMSL). The airport has one basic runway, Runway 5/23. For the 12-month period ending in December 2006, the most recent year for which data is available, the airport hosted 150 annual aircraft operations, with all operating aircraft classified as transient general aviation (AIRNAV 2013).

The Chocolate Mountain Aerial Gunnery Range (CMAGR) is approximately 15 miles south of the site. The U.S. Navy and Marines use this approximately 459,000-acre area for military aircrew training in air combat maneuvering and tactics, airborne laser system operations, gunnery, live fire aerial gunnery practice, aerial bombing, rocketry, and strafing (attacking ground targets). The Department of the Navy (DoN) owns approximately half of the CMAGR, while the Bureau of Land Management (BLM) manages the other half. The military’s right to use the BLM-managed land expires in 2014, so the DoN is requesting that Congress renew its use of the land and continue the military reservation for another 25 years (DON 2012).

The project site also lies within the vicinity of Department of Defense military training routes VR-296, VR-1265, VR-1268, and IR-218.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

The direct and indirect impacts of the proposed PSEGS on the traffic and transportation system are discussed in this section. The assessment of traffic- and transportation-related impacts is based on an analysis which compares the current traffic and transportation conditions to conditions that would exist during construction and operation of the PSEGS.

CONSTRUCTION PERIOD TRAFFIC IMPACTS AND MITIGATION

Level of Service (LOS) is a generally accepted measure used by traffic engineers and planners to describe and quantify the traffic congestion level on a particular roadway or intersection in terms of speed, travel time, and delay. The *Highway Capacity Manual 2010*[3], published by the Transportation Research Board Committee on Highway Capacity and Quality of Service, includes six levels of service for roadways and intersections. These levels of service range from LOS A, the best and smoothest operating conditions, to LOS F, the worst, most congested operating conditions. Staff used LOS to quantify the traffic congestion experienced on local roadways before and during project construction.

Workers for the project would commute from the surrounding areas. Workers from regional areas would find temporary housing in Blythe, Indio or Ehrenberg (CEC 2013w). Workers with permanent residences in Palm Springs, the Los Angeles basin, and the Indio area would travel east on I-10 to the project site, while workers from Blythe and the Arizona communities of Quartzsite, Ehrenberg, and Cibola would follow I-10 west to the project site. Workers residing permanently in San Bernardino County could follow either I-10 west or I-10 east to the project site.

Construction of the PSEGS would occur over 33 months, with peak construction expected to occur during Month 22 (in the year 2015). The average daily workforce would be approximately 998 workers, with a peak daily workforce of approximately 2,311 workers. The construction workforce would be higher than that proposed for the approved Palen Solar Power Project (PSPP), which had an average daily workforce of 566 workers and a peak daily workforce of 1,141 workers.

PSEGS construction workers would not all arrive at or depart from the project site at the same time, as the project owner has proposed that construction workers would be spread out over two or three work shifts. Also, some of the construction workers would be working offsite on the transmission and gas lines, further reducing the number of workers that would simultaneously arrive at and depart from the project site. The project owner estimates that the day shift, which would begin at 5 AM, would consist of 790 average daily workers and 1,700 peak daily workers. The project owner also assumes that carpooling would result in a 7.5 percent reduction[4] in construction vehicle trips.

[3] The *Highway Capacity Manual* (HCM) is the most widely used resource for traffic analysis. The Highway Capacity Manual is prepared by the Transportation Research Board Committee on Highway Capacity and Quality of Service. The current edition was published in 2010.

[4] This reduction is based on the assumption that 15% of workers would carpool. This carpooling estimate is based on the remote location of the project site, the high cost of gas, and the assumption that some

However, the traffic analysis for this project is conservative and evaluates the worst-case construction traffic scenario. The analysis evaluates trips made by all 2,311 construction workers, not just day shift workers, during the peak construction period during the peak hour of traffic in the project area. Also, the traffic analysis does not take into account the 7.5 percent reduction in construction vehicle trips and instead uses the assumption that no carpooling would occur. For a summary of peak construction traffic impacts to study roadways, see **Traffic and Transportation – Table 2** (below). This table compares peak hour traffic volume and level of service (LOS) on all study roadways during the year 2015 without the PSEGS and the year 2015 with the PSEGS (during peak construction). During peak construction and peak hour, I-10 west and east of the PSEGS would be expected to operate at LOS A, a free-flowing traffic condition. However, Corn Springs Road would be expected to operate at LOS F, an LOS classification indicating the most congested traffic conditions. This would be a significant traffic impact. Congested LOS F traffic conditions on Corn Springs Road could potentially cause a bottleneck at the I-10/Corn Springs Road interchange, causing project traffic to spill over onto I-10, resulting in traffic stacking on I-10 near the project site.

Traffic and Transportation – Table 2
Peak Hour Volumes and LOS on Study Roadways During Peak Construction

Roadway Segment	Existing (2013) Volume	LOS	Peak Construction Year (2015) Volume without PSEGS	LOS	**Peak Construction Year (2015) Volume with PSEGS**	**LOS**
I-10 West of the PSEGS	1,611	A	1,643	A	**2,799**	**A**
I-10 East of the PSEGS	1,600	A	1,632	A	**2,788**	**A**
Corn Springs Road	2	A	2	A	**2,311**	**F**

Notes:
- Volume is peak hour volume.
- Caltrans Year 2013 traffic volumes were expanded to Year 2015 using the rate of growth (1%/year) seen between 2012 and 2013 ((Palen 2013ee, Palen 2013uu, CEC 2013y).

Staff also evaluated peak construction peak hour traffic impacts at intersections near the project site. See **Traffic and Transportation – Table 3** (below), which compares peak hour delay and LOS on all study intersections during the Year 2015 without the PSEGS and the Year 2015 with the PSEGS (during peak construction). As shown in the table, the I-10 Westbound Ramps/Corn Springs Road and I-10 Eastbound Ramps/Corn Springs Road intersections would operate at acceptable levels of LOS C or better during the evening peak hour, but would operate at congested, unacceptable levels of LOS F during the morning peak hour[5]. The LOS F conditions that would be experienced

workers would stay nearby at the same hotels and would carpool to and from the site. With an average of two people per vehicle, there would be a 7.5% reduction in construction vehicle trips.

[5] The LOS is better during the evening peak hour because much of the traffic leaving the site would be able to enter I-10 as a free, uncontrolled movement (without a stop sign).

at these intersections during the morning peak hour would constitute a significant traffic impact.

Traffic and Transportation – Table 3
Peak Hour Delay and LOS on Study Intersections During Peak Construction

Intersection	Existing (2013) Delay and LOS		Peak Construction Year (2015) without PSEGS: Delay and LOS		**Peak Construction Year (2015) with PSEGS: Delay and LOS**	
	AM Peak	PM Peak	AM Peak	PM Peak	**AM Peak**	**PM Peak**
I-10 Westbound Ramps/Corn Springs Road	5.8 seconds LOS A	7.7 seconds LOS A	5.8 seconds LOS A	7.7 seconds LOS A	**>50 seconds** **LOS F**	**0.5 seconds** **LOS A**
I-10 Eastbound Ramps/Corn Springs Road	6.3 seconds LOS A	2.9 seconds LOS A	6.3 seconds LOS A	2.9 seconds LOS A	**>50 seconds** **LOS F**	**19.7 seconds** **LOS C**

Notes:
- Volume is peak hour volume.
- Caltrans Year 2013 traffic volumes were expanded to Year 2015 using the rate of growth (1%/year) seen between 2012 and 2013 (Palen 2013ee, Palen 2013uu, CEC 2013y).

To mitigate the PSEGS's significant peak construction traffic impacts to Corn Springs Road and to the I-10 Westbound Ramps/Corn Springs Road and I-10 Eastbound Ramps/Corn Springs Road intersections during the morning peak hour, staff has proposed Condition of Certification **TRANS-1**, which requires the project owner to prepare a traffic control plan to reduce traffic impacts through means such as staggered work shifts, off-peak work schedules, and/or restricting travel to and departures from the project site to 10 or fewer vehicles every three minutes. This condition is the same as that proposed for the original project, with some minor modifications specifically asking for a detailed plan for construction worker arrival and departure times, and methods to ensure worker compliance.

It should be noted that the traffic analysis above does not include truck trips, but that inclusion of truck trips would not significantly alter the outcome of the traffic LOS impacts analysis. During construction, the average number of daily truck trips would be 20 roundtrips (40 one-way trips). During peak construction, the number of daily truck trips would be higher at approximately 45 daily roundtrips (90 daily one-way trips) (CEC 2013t, Palen 2012a, Palen 2013g). Truck trips for the PSEGS would be higher than those for the PSPP. The PSPP as approved would have generated an average of approximately 10-15 daily truck roundtrips (20-30 one-way trips) during construction, with 20 daily roundtrips (40 one-way trips) during peak construction (Palen 2012a). To ensure that slow-moving truck delivery traffic would not cause back-ups and resulting impacts to traffic LOS, Condition of Certification TRANS-1 requires limitation of truck deliveries to off-peak construction commute hours and/or staggering of truck deliveries throughout the day.

Oversized or overweight trucks with unlicensed drivers could be hazardous to the general public and/or damage roadways. Condition of Certification TRANS-2 requires that the project owner comply with limits on vehicle sizes and weights and driver licensing regulations. Because construction traffic and trucks could also damage roadways, Condition of Certification TRANS-3 requires that prior to construction, the project owner repave and restore all roads to a condition that could accommodate construction traffic, and immediately restore all roads damaged by construction activities. Construction and/or construction repairs could require encroachment into public rights-of way. **TRANS-4** requires that the owner obtain necessary encroachment permits from Caltrans and any other relevant jurisdictions and comply with limitations for encroachment into public rights-of-way.

OPERATION TRAFFIC IMPACTS AND MITIGATION

Analysis of the originally proposed project indicated that with 134 daily operations workers and approximately 6 truck trips per day, there would be no significant impacts to LOS at the studied road segments or intersections during project operations. As part of the original project, staff found that LOS on all roadways and intersections would continue to operate at LOS A, the pre-project LOS, which is better than the minimum LOS of C.

The PSEGS proposes approximately 6 truck trips per day, the same as for the approved PSPP, but 100 daily operation workers (40 during the day and 60 during the evening), a smaller number than the 134 daily operation workers proposed as part of the PSPP (Palen 2012a). However, to be conservative, the operation traffic impact analysis assumes 134 operation workers, the number of daily operation workers from the approved PSPP (Palen 2013ee). See **Traffic and Transportation – Table 4**, Peak Hour Volumes and LOS on Study Roadways During Project Operation, and **Traffic and Transportation – Table 5**, Peak Hour Delay and LOS on Study Intersections During Project Operation. These tables show that during project operation, all roadways and intersections would operate at LOS A. Therefore, the PSEGS would result in less than significant operation impacts to LOS.

Traffic and Transportation – Table 4
Peak Hour Volumes and LOS on Study Roadways During Project Operation

Roadway Segment or Intersection	Year 2016 Volume without PSEGS	Year 2016 Volume with PSEGS	LOS
I-10: West of the project site	1,659	1,726	A
I-10: East of the project site	1,648	1,715	A
Corn Springs Road	2	136	A

Notes:
Caltrans Year 2013 traffic volumes were expanded to Year 2016 using the same rate of expansion (1%/year) seen between 2012 and 2013 (Palen 2013ee, Palen 2013uu, CEC 2013y).

Traffic and Transportation – Table 5
Peak Hour Delay and LOS on Study Intersections During Project Operation

	Year 2016 without PSEGS		**Year 2016 with PSEGS**	
Study Intersection	**AM Peak Delay/LOS**	**PM Peak Delay/LOS**	**AM Peak Delay/LOS**	**PM Peak Delay/LOS**
I-10 Westbound Ramps/Corn Springs Road	5.8 seconds LOS A	7.7 seconds LOS A	4.6 seconds[6] LOS A	1.2 seconds LOS A
I-10 Eastbound Ramps/Corn Springs Road	6.3 seconds LOS A	2.9 seconds LOS A	8.5 seconds LOS A	6.2 seconds LOS A

Notes:
Caltrans Year 2013 traffic volumes were expanded to Year 2016 using the same rate of expansion (1%/year) seen between 2012 and 2013 (Palen 2013ee, Palen 2013uu, CEC 2013y, Palen 2013ddd).

EMERGENCY SERVICES VEHICLE ACCESS

The project includes a proposed primary access from Corn Springs Road. The proposed primary access provides adequate site access for emergency vehicles traveling to the site from I-10 and exiting on Corn Springs Road.

Due to site constraints increasing the difficulty of providing a secondary access road, **Worker Safety and Fire Protection** staff is instead requiring at least two emergency access gates, one each on the north fence line and south fence line. These gates would not encroach on Caltrans' right-of-way. In the event of an emergency, if the main access road was blocked, all-terrain fire engines would be able to access the site through these gates. **Worker Safety and Fire Protection** staff is requiring that PSEGS "buy into" the Riverside County Fire Department's all-terrain fire engines purchased by the Genesis Solar Energy Project by paying the Genesis project owners the PSEGS's fair share of the cost of the purchase and maintenance of the fire engines. See the **WORKER SAFETY AND FIRE PROTECTION** section of this Final Staff Assessment (FSA) for more details. Traffic and Transportation staff finds these alternative emergency vehicle accesses adequate from a traffic and transportation perspective.

WATER, RAIL, BUS AND AIR TRAFFIC

The proposed PSEGS is not adjacent to a navigable body of water and therefore would not alter water-related transportation. The proposed modified project also would not alter rail or bus transportation. No rail tracks or bus services exist on or near the project site.

The project could potentially impact aviation activities. See the discussion below.

[6] AM peak delay is actually less during operation of the PSEGS because of the project's addition of vehicles making free movements through the intersection with no delay. These vehicles reduce the average vehicle delay for the intersection (Palen 2013ddd).

Aviation Activities

Height

The project site, with its proposed 760-foot-high solar towers, lies within the vicinity of Department of Defense military training routes VR-296, VR-1265, VR-1268, and IR-218. Michael A. Aimone, Executive Director of the Department of Defense (DoD) Siting Clearinghouse, submitted a letter to the Energy Commission stating that while DoD predicts that the project would impact these military training routes, DoD believes these impacts can be mitigated and is not opposed to construction of the project. If the PSEGS is constructed, military aircraft would fly around the PSEGS or at higher altitudes.

The PSEGS's 760-foot-high solar towers would exceed a height of 200 feet above ground level (AGL). Therefore, under Title 14, Part 77 of the Code of Federal Regulations, the towers would require review by the Federal Aviation Administration (FAA). In March 2013, the project owner submitted to the FAA for each solar tower a Form 7460-1 "Notice of Proposed Construction or Alteration" as required. The FAA responded to the submittal on July 18, 2013 with a "Determination of No Hazard to Air Navigation". The FAA stated that the Determination of No Hazard included any temporary construction equipment such as cranes or derricks with heights of up to 760 feet, but that any temporary construction equipment with heights of greater than 760 feet would require separate notice to the FAA (Palen 2013 ccc). To ensure compliance, staff is proposing Condition of Certification **TRANS-5** to require that the project owner notify the FAA of any construction equipment exceeding 760 feet in height.

In the FAA's Determination of No Hazard for the solar towers, the FAA required as a condition of the Determination that the towers be marked and lighted in accordance with FAA Advisory Circular 70/7460-1 K Change 2, Obstruction Marking and Lighting, a med-dual system - Chapters 4,8(M-Dual), &12 (Palen 2013 ccc). To ensure compliance, staff is proposing **TRANS-6,** which would require the project owner to install obstruction marking and lighting on the solar towers as specified above by the FAA. The form of lighting required by the FAA and by **TRANS-6** is in accordance with the recommendations of **Biological Resources** staff to use flashing lights at night. This would reduce the potential for wildlife (birds and bats in particular) to be attracted to the project site where they could be subject to collisions or other anthropogenic sources of injury or mortality.

With implementation of Conditions of Certification **TRANS-5 and TRANS-6**, the project would comply with FAA regulations, and the project structures would not create a significant impact to aviation.

Thermal Plumes

The PSEGS's wet surface air cooler, auxiliary boiler and nighttime boiler would produce thermal plumes, hot columns of gas discharged toward the sky. Thermal plume velocities would be greatest at the discharge points, with plume velocities decreasing with increasing altitude. Aircraft flying through parts of thermal plumes exceeding 4.3 meters/second (m/s) in vertical velocity could experience moderate to severe turbulence, which could compromise pilot control and aircraft stability.[7]

To determine whether the thermal plumes emitted from the PSEGS would exceed 4.3 m/s at altitudes where aircraft could fly, Energy Commission Air Quality staff (Jacquelyn Leyva Record) modeled plume velocities for the project's wet surface air cooler, auxiliary boiler, and nighttime boiler. Air Quality staff found that in each case, thermal plume vertical velocity exceeded 4.3 m/s at altitudes of approximately 200 feet above ground level (AGL) or below. At altitudes higher than approximately 200 feet AGL, thermal plume velocity was below the critical 4.3 m/s threshold for endangering aircraft. Aircraft would generally be flying at altitudes much higher than 200 feet AGL; therefore, the thermal plumes would have less than significant impacts to aviation.

GLINT AND GLARE IMPACTS ON MOTORISTS AND PILOTS

The proposed PSEGS's mirrored heliostats and solar receiver steam generator (SRSG) tower would generate glint and glare, which could cause impacts to both ground traffic and aviation if sufficient to compromise a driver's or pilot's ability to operate his/her vehicle or aircraft. PSEGS Unit 2 is especially close to I-10, at a distance of approximately 4,500 feet from the highway.

A thorough assessment of the PSEGS's potential glint and glare impacts is provided in **APPENDIX TT1 – VISUAL SAFETY IMPACT ASSESSMENT**. For details, please consult this appendix. The sections below summarize the conclusions discussed in the appendix.

Retinal Damage

Retinal damage is a permanent loss of visual function in the affected retinal region and can be caused by either photothermal or photochemical mechanisms. Photothermal damage is the physical damage to the retina that can occur from high levels of irradiance which thermally overload and burn the retina. Photochemical damage is associated with both long-duration exposure times and lower-wavelength (higher-energy) light exposure. For photothermal retinal damage, the highest level of exposure considered to be safe is called the Maximum Permissible Exposure (MPE) limit. The MPE is an international standard and is specified for both momentary and continuous exposures. Calculations of the retinal irradiance from both the PSEGS's heliostats and

[7] This is based on staff's review of a 2004 safety circular (AC 139-05(0)), prepared by the Australian Government Civil Aviation Safety Authority, that noted "aviation authorities have established that an exhaust plume with a vertical velocity in excess of 4.3 meters per second (m/s) may cause damage to an aircraft airframe or upset an aircraft when flying at low levels" (CASA 2004). In their safety study on thermal plumes the FAA noted that they "do not necessarily approve/disapprove or warrant the data contained in the CASA AC 139-05." The safety team accepted "the information and data contained in AC 139-05 as a valid representation of hazardous exhaust velocities" (FAA 2006).

SRSGs have demonstrated that exposures at or above the MPE limit are not possible outside the solar plant's boundaries. Therefore, there is no risk of photothermal retinal damage to motorists or pilots. However, on-site workers within plant boundaries could experience a level of exposure exceeding the MPE for a very limited and unique set of conditions and tower observation points. See the **WORKER SAFETY AND FIRE PROTECTION** section of this FSA for conditions of certification which would mitigate this impact by requiring site workers to wear the appropriate personal protection equipment (PPE) in the form of protective sunglasses.

Photochemical retinal damage is both dose-dependent and cumulative in nature. Motorists and pilots would not be exposed to light from the PSEGS for long enough periods of time to experience photochemical retinal damage. Only on-site workers would be at risk of photochemical retinal damage due to their extensive exposure to the ambient (background) light of the site (being outdoors essentially all day) and to the additional illumination from the heliostat field and SRSGs. See the **WORKER SAFETY AND FIRE PROTECTION** section of this FSA for conditions of certification which would mitigate this impact by requiring site workers to wear the appropriate PPE in the form of protective sunglasses.

Glint and Glare

Glint and glare may cause a viewer to experience difficulty seeing. While glint is a temporary flash of brilliant light, glare is a more sustained bright light. Additionally, glare is generally divided into two class types: discomfort glare and disability glare. Discomfort glare results in an instinctive desire to look away from a bright light source or difficulty in seeing a task. Disability glare renders the task impossible to view, such as when driving westward at sunset.

Heliostats are sources of both glint and glare: glint from direct solar reflections and sustained glare from reflections of either the sun or sky background. The SRSGs are sources of sustained glare. This glint and glare could potentially impact motorists on I-10 and pilots flying near the project site. Staff recognizes that definitive standards for the safety effects of glint and glare, from distraction to discomfort to disability, do not exist and there are no reliable metrics for determining the glint and glare thresholds for a significant impact to traffic and transportation.

Glint and Glare from the Heliostats

Motorists could potentially experience glint and glare impacts from the PSEGS's heliostats. The heliostats would commonly produce sky reflections. These would not be a significant source of glint and/or glare that would be experienced by motorists. However, during both project construction and operation, direct solar reflections from the heliostats (DSRH) would cause discomfort glare to motorists within 10 miles of the project site, and possibly at even further distances. This would be a significant impact. To mitigate this impact, staff proposes Condition of Certification **TRANS-7**, which would require the project owner to develop and implement a heliostat positioning and monitoring plan to minimize the frequency of DSRH events during the testing, calibration and operational phases of the PSEGS. With implementation of **TRANS-7**, glint and glare impacts to motorists would be less than significant.

Pilots could also experience glint and glare impacts from the PSEGS's heliostats. Sky reflections from the heliostats would be noticeable to pilots but not significant. DSRH events would be more visually prominent to pilots than indirect sky reflections. Because the heliostats point toward the sky when in standby position, airborne DSRH events are inevitable. Their frequency and severity would depend on the frequency, range and geometry of aircraft operations in the project vicinity. However, direct solar reflections are expected events for pilots, commonly occurring as reflections from lakes, streams, and man-made objects such as metal roofing. Pilots are generally very adept at dealing with such events, and such events are expected to cause only mild discomfort. Also, implementation of **TRANS-7** would require the project owner to maximally limit DSRH on all observers through effective heliostat positioning. This would ensure that the number of heliostats pointing skyward would be minimized to only those necessary. With implementation of **TRANS-7**, individual or sequential DSRH events may cause mild discomfort to pilots but are not expected to induce severe discomfort or disability glare that would compromise pilots' abilities to operate their aircraft. Heliostat glint and glare impacts to pilots are expected to be less than significant.

Glare from the SRSGs

The SRSGs would produce unavoidable glare. Staff concludes that sustained glare from the SRSGs during nominal operating conditions (where luminance would be less than $1x10^6$ cd/m^2) would not produce discomfort or disability glare that would interfere with motorists' or pilots' abilities to operate their vehicles and planes, respectively. However, at higher luminance levels, the SRSGs could produce discomfort or disability glare that would significantly impact drivers on I-10. To ensure that the SRSGs operate at acceptable luminance levels (less than $1x10^6$ cd/m^2) that would not impact drivers, staff has proposed Condition of Certification **TRANS-8** to require a solar power tower receiver luminance and monitoring plan. **TRANS-8** would provide procedures for identification and mitigation of visual distraction, discomfort glare, or disability glare effects with the potential of causing significant impacts to motorists.

MOTORIST ACCIDENTS

Staff analyzed the potential for project glint and glare to cause motor vehicle accidents on I-10. For this analysis, see **APPENDIX TT2 – RISK OF IMPACTS TO VEHICLE OPERATORS DRIVING ON INTERSTATE-10 DUE TO GLINT AND GLARE ASSOCIATED WITH THE PALEN SOLAR ELECTRIC GENERATING SYSTEM**. In summary, staff found that under normal operating conditions, the risk of glint or glare causing vehicular accidents would be less than significant. However, if a heliostat during construction, before implementation of heliostat control algorithms, or a malfunctioning heliostat during operations were to be oriented even for a few seconds facing I-10 such that drivers would experience a direct (or within 10 degrees) reflection from a heliostat, visual impairment (flash blindness or disability glare) could occur and result in a vehicular accident. See **APPENDIX TT2** for more information.

Proposed Condition of Certification **TRANS-7** would require implementation of a heliostat positioning and monitoring plan which would mitigate these potential impacts to less than significant. **TRANS-7** requires that the project owner cover the mirrored surfaces of the heliostats during construction until they are properly seated, oriented and under computer control. It also requires the project owner to implement early heliostat computer control algorithms during construction to ensure that heliostats would not reflect onto I-10 motorists or any other ground-based observers during construction or operation. With implementation of **TRANS-7**, the PSEGS's potential to cause motor vehicle accidents would be less than significant.

TRANSPORTATION OF HAZARDOUS MATERIALS

Both the construction and operation of the proposed PSEGS would involve the transportation of hazardous materials to the site. The transport vehicles would be required to follow federal and state regulations governing proper containment vessels and vehicles, including appropriate identification of the nature of the contents.

In addition to the governing federal and state regulations, Condition of Certification **TRANS-9** requires that the project owner secure permits and/or licenses from the California Highway Patrol and Caltrans for the transportation of hazardous materials. See the **HAZARDOUS MATERIALS MANAGEMENT** section of this FSA for more information. With implementation of Condition of Certification **TRANS-9**, the PSEGS would cause less than significant impacts to roadways and the traveling public from transportation of hazardous materials.

PARKING CAPACITY

Construction period parking demands would be accommodated by a construction laydown area of approximately 203 acres. This parking area would accommodate all construction workforce vehicles.

During project operation, employees would park on-site at the common facilities area and at each power block. The project would provide 38 spaces at the common facilities area, 19 spaces at the Unit 1 power block, and 19 spaces at the Unit 2 power block for a total of 76 parking spaces. These parking areas would provide sufficient parking for all operation employees on-site simultaneously (40 workers during the day and 60 workers during the evening).

Because the PSEGS supplies an adequate amount of on-site parking, the project would not result in any parking spill-over to sensitive areas and would not create any adverse impacts.

PROJECT-RELATED FUTURE ACTIONS – TRANSPORTATION AND TRAFFIC

The original Palen analysis included a discussion of the SCE Red Bluff Substation as an associated reasonably foreseeable project. It also included an analysis of traffic generated by construction of the substation. Because construction of the SCE Red Bluff Substation is currently underway and anticipated to be completed before start of construction of the PSEGS, there is no need to analyze substation traffic impacts at this point.

CUMULATIVE IMPACTS AND MITIGATION

A project may result in a significant adverse cumulative impact when its effects are cumulatively considerable. *Cumulatively considerable* means that the incremental effects of an individual project are significant when viewed in connection with the effects of (1) past projects; (2) other current projects; and (3) probable future projects (California Code Regulation, Title 14, section 15130).

The potential exists for substantial future development throughout the entire Southern California Desert Region as well as on the Interstate 10 (I-10) corridor in eastern Riverside County. In this document, Energy Commission staff has limited the traffic and transportation analysis to the I-10 corridor of eastern Riverside County within a range starting approximately 20 miles west of the project site and ending approximately 40 miles east of the project site near Blythe, CA. Staff selected this range because it encompasses many existing and proposed development projects, including many other energy projects, that could generate traffic traveling on I-10 near the PSEGS site. See **TRAFFIC AND TRANSPORTATION FIGURE 3 – TRAFFIC AND TRANSPORTATION CUMULATIVE PROJECTS** for a list of current, pending, and foreseeable development projects in this area.

Traffic LOS on I-10 could degrade with the volume of construction traffic generated by the PSEGS in combination with traffic generated by the identified additional projects shown in **TRAFFIC AND TRANSPORTATION FIGURE 3 – TRAFFIC AND TRANSPORTATION CUMULATIVE PROJECTS**. Proposed Condition of Certification **TRANS-1** would ensure that the PSEGS's contribution to cumulative impacts would be less than significant by requiring the PSEGS project owner to implement staggered work shifts and/or off-peak work schedules, and/or to restrict travel to and departures from the project site to 10 or fewer vehicles every three minutes. With implementation of **TRANS-1**, the project's impacts to Corn Springs Road and the I-10 ramp intersections during the morning peak hour would be minimized, thus averting bottlenecks that could cause traffic back-ups on I-10, which could potentially contribute to cumulative impacts. With implementation of **TRANS-1**, I-10 is expected to continue to operate at LOS A in the project area during peak construction. PSEGS operations traffic also would not contribute to cumulative traffic impacts, as operations traffic would be minimal.

The PSEGS project would not combine with other nearby existing or proposed solar projects to cause significant cumulative glint and glare impacts to motorists. There are a couple of other nearby large-scale solar projects involving mirrors, such as the Genesis Solar Energy Project (GSEP), which uses parabolic troughs and is under construction, and the Blythe Solar Power Project (BSPP), approved by the Energy Commission to use parabolic trough technology, although an amendment petition was filed in June 2012 to use solar photovoltaic (PV) technology instead. However, these projects are sufficiently far from the PSEGS so that motorists on I-10 would not experience glint and glare impacts from either of these projects simultaneously with the most severe glint and glare impacts from the PSEGS. The GSEP is approximately 15 miles east of the proposed PSEGS site and the BSPP is approximately 30 miles east of the proposed

PSEGS site. Furthermore, if the BSPP is converted to PV technology, it would emit very little glint and glare, as PV panels are designed to absorb rather than reflect sunlight.

The PSEGS project also would not combine with other nearby existing or proposed projects to cause significant cumulative glint and glare impacts to pilots. Many nearby energy projects use solar photovoltaic technology, which is designed to absorb solar energy rather than reflect it, and therefore does not generate glint or glare impacts to pilots. Viewed by a pilot from the air, a photovoltaic plant looks similar to a body of water, such as a lake. Two other nearby power plant projects, the BSPP (approved by the Energy Commission) and GSEP (approved by the Energy Commission and under construction), use mirror technology, specifically parabolic troughs. These projects could potentially produce glint and glare experienced by pilots. However, an amendment has been filed with the Energy Commission to convert the BSPP to photovoltaic technology, which would not generate significant glint or glare impacts to pilots, and the GSEP is approximately 15 miles east of the PSEGS site, making it unlikely that pilots would experience glint and glare from both projects at the same time.

In conclusion, the PSEGS's cumulative impacts to aviation would be less than significant.

COMPLIANCE WITH LORS

The PSEGS project as proposed and with conditions of certification as mitigation would comply with federal, state, and local LORS. See **Traffic and Transportation – Table 6**, below, for a summary of the PSEGS's conformance with all applicable LORS.

Traffic and Transportation – Table 6
PSEGS Compliance with Adopted Traffic and Transportation LORS

Applicable LORS	Description
Federal	
Title 14, Code of Federal Regulations, Aeronautics and Space, part 77 - Objects Affecting Navigable Airspace (14 C.F.R., part 77)	These regulations establish standards for determining physical obstructions to navigable airspace; set noticing and hearing requirements; provide for aeronautical studies to determine the effect of physical obstructions on the safe and efficient use of airspace; and oversee the development of antenna farm areas. <u>Consistent</u>: In March 2013, the project owner submitted to the FAA for each solar tower a Form 7460-1 "Notice of Proposed Construction or Alteration" as required by FAA regulations for structures exceeding 200 feet in height. The FAA responded to the submittal on July 18, 2013 with a "Determination of No Hazard to Air Navigation". As a condition of the determination, the FAA is requiring that the towers be marked and lighted in accordance with FAA Advisory Circular 70/7460-1 K Change 2, Obstruction Marking and Lighting, a med-dual system - Chapters 4,8(M-Dual), &12. For project compliance with FAA regulations, staff is proposing Condition of Certification **TRANS-5** to require that the project owner notify the FAA of any construction equipment exceeding 760 feet in height, as requested by the FAA in its Determination of No Hazard for the towers. Staff is also proposing **TRANS-6,** which would require the project owner to install obstruction marking and lighting on the solar

Applicable LORS	Description
	towers in accordance with FAA Advisory Circular 70/7460-1 K Change 2, Obstruction Marking and Lighting, a med-dual system - Chapters 4,8(M-Dual), &12, as required by the FAA. With implementation of Conditions of Certification **TRANS-5** and **TRANS-6**, the project would comply with FAA regulations.
Title 49, Code of Federal Regulations Subtitle B, parts 171-173, 177-178, 350-359, 397.9 and Appendices A-G	Addresses safety considerations for the transport of goods, materials, and substances. Governs the transportation of hazardous materials including types of materials and marking of the transportation vehicles. Consistent: PSEGS construction and operation would involve transport of hazardous materials. Enforcement would be provided by state and local law enforcement agencies and through state agency licensing and ministerial permitting (e.g., California Department of Motor Vehicles licensing, Caltrans permits), and/or local agency permitting (e.g., County of Riverside). The project owner would adhere to all required regulations. This adherence is made part of the licensing process as Condition of Certification **TRANS-9**.
State	
California Vehicle Code, sections 353; 2500-2505; 31303-31309; 32000-32053; 32100-32109; 31600-31620; California Health and Safety Code, sections 25160 et seq.	Regulates the highway transport of hazardous materials. Consistent: The PSEGS would comply with these regulations. Enforcement would be provided by state and local law enforcement agencies, and through ministerial state agency licensing and permitting and/or local agency permitting. Adherence is made part of the licensing process as Condition of Certification **TRANS-9**.
California Vehicle Code, sections 13369; 15275 and 15278	Addresses the licensing of drivers and the classification of licenses required for the operation of particular types of vehicles; also requires certificates permitting operation of vehicles transporting hazardous materials. Consistent: The PSEGS would comply with these regulations. Enforcement would be provided by state and local law enforcement agencies, and through ministerial state agency licensing and permitting and/or local agency permitting. Adherence is made part of the licensing process as Conditions of Certification **TRANS-2** and **TRANS-9**.
California Vehicle Code, sections 35100 et seq.; sections 35250 et seq.; and sections 35400 et seq.	Specifies limits for vehicle width, height, and length. Consistent: The PSEGS would comply with these regulations. Enforcement would be provided by state and local law enforcement agencies, and through ministerial state agency licensing and permitting and/or local agency permitting. Adherence is made part of the licensing process as Condition of Certification **TRANS-2**.
California Vehicle Code, section 35780	Requires permits for any load exceeding Caltrans weight, length, or width standards for public roadways. Consistent: The PSEGS would comply with these regulations. Enforcement would be provided by state and local law enforcement agencies, and through ministerial state agency licensing and permitting and/or local agency permitting. Adherence is made part of the licensing process as Condition of Certification **TRANS-2**.
California Streets and Highways Code, sections 117, 660-672	Requires permits for any load exceeding Caltrans weight, length, or width standards on County roads. Consistent: The PSEGS would comply with these regulations. Enforcement would be provided by state and local law enforcement agencies, and through ministerial state agency licensing and permitting

Applicable LORS	Description
	and/or local agency permitting. Adherence is made part of the licensing process as Condition of Certification **TRANS-2**.
California Streets and Highways Code, sections 117, 660-670, 1450, 1460 et seq., and 1480 et seq.	Regulates permits from Caltrans for any roadway encroachment for facilities that require construction, maintenance, or repairs on or across State highways and County roads. Consistent: The PSEGS would comply with these regulations. Enforcement would be provided by state and local law enforcement agencies, and through ministerial state agency licensing and permitting and/or local agency permitting. Adherence is made part of the licensing process as Condition of Certification **TRANS-3** and **TRANS-4**.
Local	
Riverside County General Plan Circulation Element	Specifies long-term planning goals and procedures for transportation infrastructure system quality. Consistent: With implementation of Condition of Certification **TRANS-1**, the PSEGS would not significantly impact traffic LOS. With implementation of all conditions of certification, the PSEGS would not significantly impact any part of the traffic and transportation system.
Riverside County General Plan Circulation Element	Specifies LOS standards to assess the performance of a street or highway system and the capacity of a roadway. Consistent: With implementation of Condition of Certification **TRANS-1**, road and intersection LOS would remain at or above Riverside County's threshold of LOS C.
Riverside County Municipal Code Title 10, Chapter 10.08, Sections 10.08.010-10.08.180	Specifies limits and permit requirements for oversize loads. Consistent: The PSEGS would comply with these regulations. Riverside County would provide enforcement and any necessary permitting. Adherence is made part of the licensing process as Condition of Certification **TRANS-2**.
Riverside County Municipal Code Title 12, Chapter 12.08, Sections 12.08.010-12.08.100	Specifies permit requirements for encroachment permits. Consistent: The PSEGS would comply with these regulations. Riverside County would provide enforcement and any necessary permitting. Adherence is made part of the licensing process as Condition of Certification **TRANS-4**.

NOTEWORTHY PUBLIC BENEFITS

While the development of the proposed modified project is intended to address the requirements of federal and state mandates to develop renewable energy, it would not yield any noteworthy public benefits related to traffic and transportation.

DEPARTMENT OF DEFENSE, OFFICE OF THE UNDER SECRETARY OF DEFENSE, MICHAEL A. AIMONE, PETITION TO AMEND APPENDIX 6-A, TN #68910, DECEMBER 17, 2012 (PALEN 2012A):

Comment: The U.S. Department of Defense (DoD) submitted a comment letter, included in the Petition to Amend, stating that while the project would likely impact military training routes in the area, they believe those impacts can be mitigated. Military aircraft would fly around the project or at higher altitudes to avoid the towers.

GALATI BLEK LLP, MARIE FLEMING/PALEN SOLAR HOLDINGS, LLC'S, INITIAL COMMENTS ON THE PRELIMINARY STAFF ASSESSMENT, TN # 71551, JULY 11, 2013 AND GALATI BLEK LLP, MARIE FLEMING/PALEN SOLAR HOLDINGS LLC'S, FINAL COMMENTS ON THE PRELIMINARY STAFF ASSESSMENT, TN # 200077, JULY 29, 2013 (PALEN 2013DD, PALEN 2013PP):

Comment: The project owner suggested after reviewing the PSA that the verification language for Condition of Certification **TRANS-6** be modified to ensure that Compliance Project Manager (CPM) inspection activities would not conflict with FAA jurisdictional requirements.

Response: Staff accepted this minor change and modified the language as part of this FSA.

Comment: The project owner also suggested that staff use for the heliostat positioning and monitoring plan condition the version proposed by the project owner as part of the May 2013 Response to Workshop Queries.

Response: Staff used this version of the condition as a starting point but added more detail to more fully mitigate the project. Also, staff did not use the project owner's proposed **TRANS-6** references to avoiding interference with operation of the Riverside County PSEC microwave tower because it is not a traffic and transportation issue. **Transmission Line Safety and Nuisance** staff does not anticipate that the heliostats would interfere with operation of the PSEC microwave tower. See the **TRANSMISSION LINE SAFETY AND NUISANCE** section of this FSA for more information.

SHAUN GONZALES, PUBLIC COMMENT, TN # 200041, JULY 25, 2013 (PC 2013A):

Comment: The PSEGS site is roughly located beneath aviation routes, including routes previously identified by the Department of Defense (DoD) as military training routes (MTR) where aircraft fly at least one segment at or below 1500 feet above ground level. CEC's PSA notes that the DoD's Siting Clearinghouse stated that the impacts of PSEGS can be mitigated, but it is not yet clear how DoD considered the use of power tower technology, or whether it conducted analysis on the potential impacts of glare and heat flux-induced turbulence on military aircraft using the routes above the proposed project site. The FAA has acknowledged the potential for heated air to cause severe turbulence over other types of power plants located under flight paths. The CEC should investigate, and explain in detail how the military plans to mitigate this impact.

Response:_ The DoD has submitted a comment letter indicating that they have no major concerns about the PSEGS project affecting their activities (Palen 2012a). Military aircraft would avoid the PSEGS power plant by flying higher above or around it. Thermal plumes would not be a concern for any aircraft flying more than 200 feet above the ground, and military aircraft would not normally fly below 200 feet, especially over the PSEGS site. Aircraft would also not fly sufficiently low to suffer from heat impacts.

See also the glint and glare analysis in this section of the FSA, which finds no significant impacts from the PSEGS to pilots as far as retinal damage and glint and glare.

COUNTY OF RIVERSIDE, JOHN J. BENOIT, COMMENTS ON THE PRELIMINARY STAFF ASSESSMENT, TN # 200094, JULY 30, 2013 (CR 2013A):

Comment: Riverside County staff stated that they wanted to review the project owner's traffic data, which was submitted on July 19, 2013 as a data response to Energy Commission staff's Data Request 14.

Response: Energy Commission Traffic and Transportation staff provided the data to Adam Rush of Riverside County on July 30, 2013.

Comment: County staff also requested that the project owner explain how it was determined that carpooling would result in a 7.5 percent reduction in carpooling vehicle trips.

Response: This reduction is based on the assumption that 15% of workers would carpool. This carpooling estimate is based on the remote location of the project site, the high cost of gas, and the assumption that some workers would stay nearby at the same hotels and would carpool to and from the site. With an average of two people per vehicle, there would be a 7.5% reduction in construction vehicle trips.

Comment: The County requested that the project owner be required to provide analyses of the pavement structure for all County roadways that could be utilized by PSEGS's construction traffic. If the analyses determine that the pavement would not provide sufficient load bearing capacity for the construction traffic, the County would require and requests that the Energy Commission require the project owner to provide road improvements specified by the County Director of Transportation.

Response: Condition of Certification **TRANS-3** now requires that the project owner provide a pavement analysis and restore all inadequate roads prior to construction.

Comment: The County requested that the project owner restore all County public roads, easements, and rights-of-way that may be damaged due to project-related construction activities to original or near original condition in a timely manner. To ensure County involvement, the County requested that Condition of Certification **TRANS-3** be revised to include reference to the County of Riverside as a participant in compliance. The County also requested that the Traffic and Transportation conditions of certification be amended to require that all monthly compliance reports (MCRs) be forwarded to the Riverside Department of Transportation for review and comment.

Response: **TRANS-3** now more explicitly specifies the County of Riverside’s role in **TRANS-3** implementation and requires that MCRs be forwarded to Riverside County. Also, **TRANS-3** would require the project owner to submit details of repairs to the County for review and comment.

Comment: The County requested that the project owner be required to provide financial security to the County, in a form acceptable to the County, to ensure the restoration or replacement of County public roads, easements, and rights-of-way.

Response: The Energy Commission would ensure that all necessary road restoration or replacement take place and would involve Riverside County. The County expressed its concerns that project glint and glare would attract the attention of motorists on I-10 and impact driver visibility, which could lead to an increased number of collisions near the project site and an increased demand for County emergency services.

Response: See **APPENDIX TT2 – RISK OF IMPACTS TO VEHICLE OPERATORS DRIVING ON INTERSTATE 10 DUE TO GLINT AND GLARE ASSOCIATED WITH THE PALEN SOLAR ELECTRIC GENERATING SYSTEM** (Glint and Glare Risk Assessment). The Glint and Glare Risk Assessment shows no significant risk of increased collisions near the project site as a result of glint and glare.

Staff has also proposed Conditions of Certification **TRANS-7** and **TRANS-8** to minimize glint and glare impacts by requiring implementation of a heliostat positioning and monitoring plan and a power tower luminance and monitoring plan.

Comment: The County also recommends that a 24-hour telephone line be established and published for complaints from the public, motorists, and pilots concerning the glint and glare coming from the project.

Response: Condition of Certification **TRANS-7** requires posting of a complaint line, and both **TRANS-7** and **TRANS-8** establish procedures for complaint investigation and resolution.

RIVERSIDE COUNTY, AIRPORT LAND USE COMMISSION, ED COOPER, COMMENTS REGARDING PRELIMINARY STAFF ASSESSMENT OF THE PALEN SOLAR ELECTRIC SYSTEM PETITION TO AMEND, TN # 200112, JULY 30, 2013 (CR 2013B):

Comment: Pursuant to Policy 1.5.3(c) of the Countywide Policies of the 2004 Riverside County Airport Land Use Compatibility Plan, proposals "for construction or alteration of a structure (including antennas) taller than 200 feet above the ground level at the site" constitute major land use actions subject to ALUC review "[r]egardless of location within Riverside County." Therefore, if this project were not on federal land, it would be subject to ALUC review, as well as County review, absent the Energy Commission's certification authority. ALUC requests the opportunity to consider the project locally at a public hearing in Riverside County and forward its conditions to the Energy Commission for its consideration.

Response: There is still opportunity for the ALUC to comment further on the project. Staff anticipates that Evidentiary Hearings for the PSEGS will be held in late October, and any written or oral comments the ALUC provides may be entered into the record at that time. Also, after the hearings, the Energy Commission will release a Presiding Members Proposed Decision (PMPD), which requires a 30-day public review period during which the ALUC may also submit comments.

The FAA has issued a “Determination of No Hazard” for the tower structures and included requirements for obstruction marking and lighting (Palen 2013 ccc). Staff has proposed conditions of certification **TRANS-5** and **TRANS-6** to require notification of the FAA for construction equipment exceeding 760 feet in height and marking and lighting of all tower structures in accordance with FAA requirements provided in the Determination of No Hazard.

Comment: The thermal plume could affect low-flying emergency medical evacuation helicopters. Provision should be made for the wet surface air cooler, auxiliary boiler, and nighttime boiler to be shut down in the event of an (on-site) emergency requiring an airborne evacuation.

Response: A revision to Conditions of Certification **WORKER SAFETY-1** and **WORKER SAFETY-2** is proposed by staff to include a requirement that the project owner submit an Emergency Medical Evacuation Plan as part of the Emergency Response Plan, one for the construction period and another for operations. Staff does not anticipate emergency medical helicopters landing within the heliostat fields due to space constraints; instead, emergency medical helicopters would likely land at the perimeter of the facility, or in the common area. There is also no reason for an emergency medical helicopter to fly within 200 feet above the wet surface air cooler, auxiliary boiler, and nighttime boiler while landing, or through any part of the plant facility. Thus, staff believes that no helicopters would be at risk from a thermal plume at the site. The requirement that an Emergency Medical Evacuation Plan be prepared and submitted to the Compliance Project Manager (CPM) for review and approval would ensure that the helicopters are not placed at risk. See the **WORKER SAFETY AND FIRE PROTECTION** section of this FSA for more information.

Comment: Solar flux could potentially burn the occupants of low-flying emergency medical evacuation helicopters. In the event that an emergency medical evacuation is needed from a location at or near the tower and/or the heliostats, it may be necessary to shut down the entire facility to reduce the temperatures sufficiently to allow a helicopter to safely exit the facility, or to transfer the patient(s) to a ground location that would allow the helicopter to safely land and take off without entering the superheated airspace.

Response: See above response.

Comment: This is one of many solar energy generation facilities (both thermal facilities subject to Energy Commission certification and photovoltaic facilities subject to county permitting) proposed along the Interstate 10 corridor between the privately operated Desert Center Airport and public use Blythe Airport. Airport Land Use Commissioners have expressed increasing concerns regarding the adverse cumulative impacts created by these facilities on an airport.

Response: Cumulative impacts to airports from the PSEGS in combination with other nearby solar facilities are less than significant. Please see the "Cumulative Impacts" portion of the Traffic and Transportation section of this FSA for more information.

STATE OF CALIFORNIA, DEPARTMENT OF TRANSPORTATION, DANIEL KOPULSKY, TN # 200198, AUGUST 12, 2013 (DOT 2013A):

Access Road

Comment: Right-of-way (ROW) for I-10 extends beyond the Corn Springs Road Interchange. Design and construction for the project access road connection to Corn Springs Road Interchange shall follow the guidelines in Caltrans Highway Design Manual Section 504.8 – Access Control:

> http://www.dot.ca.gov/hq/oppd/hdm/hdmtoc.htm.

Response: Staff added the following language to Condition of Certification **TRANS-4**, which requires the project owner to obtain the required encroachment permits:

> "Design and construction for the project access road connection to the Corn Springs Road Interchange shall follow the guidelines in Caltrans Highway Design Manual Section 504.8 – Access Control:
>
> > http://www.dot.ca.gov/hq/oppd/hdm/hdmtoc.htm.

Comment: The delivery of turbine equipment, construction materials, water trucks, tractor trailers, and other heavy equipment may have an impact on the State Highway System. It is recommended that the project owner restore all public roads, easements, and rights-of-way that have been damaged due to project-related construction activities to original or near-original condition in a timely manner. Repairs and restoration of access roads may be required at any time during the construction phase of the project to assure safe ingress and egress.

Response: Condition of Certification **TRANS-3** requires this.

Glint and Glare

Comment: Caltrans staff requests further consultation with Energy Commission staff before mitigation measures for glint and glare are proposed. Caltrans staff requests an extension for submitting any glint and glare comments.

Response: Glint and glare comments are welcome, but cannot be considered by staff in this FSA. When comments are received, they will be addressed during the next stage of our process. Staff anticipates that Evidentiary Hearings for the PSEGS will be held in late October, and any written or oral comments Caltrans provides may be entered into the record at that time. Also, after the hearings, the Energy Commission will release a Presiding Members Proposed Decision (PMPD), which requires a 30-day public review period during which Caltrans may also submit comments.

Please see the glint and glare discussion and glint and glare appendix in this section of the FSA. With implementation of Conditions of Certification **TRANS-7** and **TRANS-8**, glint and glare impacts would be less than significant. Condition of Certification **TRANS-7** and **TRANS-8** require coordination with Caltrans in preparation and implementation of a heliostat positioning and monitoring plan and a power tower luminance monitoring plan.

I-10 Tie Line Proposed Condition of Power Line Placement

Comment: When/if lane closures are required on the State Highway System during construction, it is recommended that Section 517 of the Encroachment Permits Manual be referenced for the proper procedures to manage traffic during construction. The manual can be accessed online at:

http://www.dot.ca.gov/hq/traffops/developserv/permits/

Response: Staff modified Condition of Certification **TRANS-1**, which requires a traffic control plan, including plans for lane closures, to include this information.

Comment: A Transportation Control Plan should be formulated to reduce traffic congestion in the event of overlapping construction schedules from the other projects in the area.

Response: See Condition of Certification **TRANS-1**, which requires preparation and implementation of a traffic control plan which would reduce traffic congestion.

Comment: It is suggested that there be appropriate signage notifications of construction traffic throughout the construction period.

Response: See Condition of Certification **TRANS-1**, which requires that signage be addressed as part of the traffic control plan.

Comment: Stagger worker times, limit truck deliveries to off-peak hours, and implement measures to ensure I-10 operates at LOS C or higher during peak travel time.

Response: See Condition of Certification **TRANS-1**, which requires these congestion reduction methods to be detailed in the traffic control plan.

Comment: Issuance of a Caltrans Encroachment Permit will be required prior to any construction within the State right-of-way and shall be in compliance with all current design standards, applicable policies, and construction practices.

Response: Condition of Certification **TRANS-4** requires the project owner to obtain all the necessary encroachment permits from Caltrans and the applicable local jurisdictions.

Transportation Permit

Comment: Caltrans has the discretionary authority to issue special permits for the movement of vehicles/loads exceeding statutory limitations on the size, weight, and loading of vehicles contained in Division 15 of the California Vehicle Code. Requests for such special permits require the completion of a Transportation Permit. For information regarding Transportation Permit application for travel within the State of California, contact:

Transportation Permits Office
1823 14th Street
Sacramento, CA 95811-7119
Main Number: (916) 322-1297

Response: Condition of Certification **TRANS-2** requires the project owner to comply with limitations imposed by Caltrans District 8 and other relevant jurisdictions on vehicle sizes and weights and driver licensing. It also requires the project owner to the obtain necessary transportation permits from Caltrans and all relevant jurisdictions for roadway use.

Project Development Procedures Manual Chapter 17 – Tranverse Utility Encroachment

Comment: New utility installations and adjustment or relocation of existing utilities may be permitted to cross a freeway or expressway. To the extent feasible and practicable, they should cross on a line generally normal to, but not less than 60 degrees, from the freeway longitudinal alignment, and preferably under the freeway. The utility should be located in such a manner that it can be serviced, maintained, and operated from outside the right-of-way, except for special cases covered under "New Utility Longitudinal Encroachments".

http://www.dot.ca.gov/hq/oppd/pdpm/pdpmn.htm#pdpm

Response: Condition of Certification **TRANS-4** requires the project owner to obtain all the necessary encroachment permits from Caltrans and the applicable local jurisdictions.

CONCLUSIONS

1. With implementation of Condition of Certification **TRANS-1**, which would require preparation and implementation of a traffic control plan, the PSEGS's construction traffic impacts would be less than significant.

2. The PSEGS's operational traffic impacts would be less than significant.

3. The PSEGS's primary emergency vehicle access is adequate. The PSEGS's alternative emergency access, which would be provided by all-terrain fire trucks and

two access gates, as required by **Worker Safety and Fire Protection** staff, is also adequate.

4. Because of the PSEGS's distance from the nearest rail and bus service, the project would have no impact on these forms of transportation.

5. With implementation of Conditions of Certification **TRANS-5** and **TRANS-6**, the PSEGS would not pose significant obstruction hazards to aircraft. **TRANS-5** would require that the project owner notify the FAA of any construction equipment exceeding 760 feet in height. **TRANS-6** would require the project owner to install obstruction marking and lighting on the solar towers.

6. The PSEGS would not produce a high-velocity thermal plume impacting aircraft.

7. The PSEGS would not cause photothermal or photochemical retinal damage to motorists or pilots outside of the PSEGS site. On-site workers within plant boundaries could potentially experience retinal damage for a very limited and unique set of conditions and tower observation points. See the **WORKER SAFETY AND FIRE PROTECTION** section of this FSA for conditions of certification which would mitigate this impact by requiring site workers to wear the appropriate personal protection equipment (PPE) in the form of protective sunglasses.

8. During project construction and operation, DSRH would significantly impact motorists by causing significant discomfort glare. With implementation of Condition of Certification **TRANS-7**, glint and glare impacts to motorists would be less than significant. **TRANS-7** would require the project owner to develop and implement a heliostat positioning and monitoring plan to minimize the frequency of DSRH events during the testing, calibration and operational phases of the PSEGS.

9. DSRH are not expected to significantly impact pilots' abilities to operate their aircraft. Pilots would experience only mild discomfort glare, not severe discomfort or disability glare. Implementation of **TRANS-7** would help ensure that impacts would remain less than significant. **TRANS-7** would require the project owner to maximally limit DSRH on all observers through effective heliostat positioning.

10. Sustained glare from the SRSGs during nominal operating conditions (where luminance would be less than $1x10^6$ cd/m^2) would not produce discomfort or disability glare that would interfere with motorists' or pilots' abilities to operate their vehicles and planes, respectively. However, at higher luminance levels, the SRSGs could produce discomfort or disability glare that would significantly impact drivers on I-10. To ensure that the SRSGs operate at acceptable luminance levels (less than $1x10^6$ cd/m^2) that would not impact drivers, staff has proposed Condition of Certification**TRANS-8** to require a solar power tower receiver luminance and monitoring plan. **TRANS-8** would provide procedures for identification and mitigation of visual distraction, discomfort glare, or disability glare effects with the potential of causing significant impacts to motorists. **TRANS-8** would help ensure that glare impacts to motorists and pilots would remain less than significant.

11. With implementation of Condition of Certification **TRANS-9**, the PSEGS would cause less than significant impacts to roadways and the traveling public from transportation of hazardous materials. **TRANS-9** requires that the project owner secure permits and/or licenses from the California Highway Patrol and Caltrans for the transportation of hazardous materials.

12. The PSEGS supplies an adequate amount of on-site parking during both construction and operation and would not create any significant parking impacts.

13. With implementation of Condition of Certification **TRANS-1**, which requires preparation and implementation of a traffic control plan, cumulative impacts from PSEGS construction traffic would be less than significant. PSEGS operations traffic would not contribute to cumulative impacts, as operations traffic would be minimal.

14. The PSEGS project would not combine with other nearby existing or proposed solar projects to cause cumulative glint and glare impacts to motorists.

15. The PSEGS project would not combine with other nearby existing or proposed solar projects to cause cumulative glint and glare impacts to pilots.

16. The PSEGS project as proposed and with conditions of certification would comply with applicable LORS related to traffic and transportation.

17. **TRANS-1** requires the owner to develop and implement a Traffic Control Plan (TCP). The TCP would include a plan for reducing peak construction traffic impacts

18. **TRANS-2** requires the owner to comply with limits on vehicle sizes and weights and driver licensing regulations.

19. **TRANS-3** requires the owner to restore all roads to a condition that can accommodate construction activities and to restore all damage caused by construction activities.

20. **TRANS-4** requires the owner to comply with limits on encroachment into public-rights-of-way and to obtain all of the necessary project permits.

21. As part of the amendment, staff is proposing a new condition of certification, **TRANS-5**, to require that the project owner notify the FAA of any construction equipment exceeding 760 feet in height.

22. As part of the amendment, staff is proposing a new condition of certification, **TRANS-6,** to require the project owner to install obstruction marking and lighting on the solar towers in accordance with FAA Advisory Circular 70/7460-1 K Change 2, Obstruction Marking and Lighting, a med-dual system - Chapters 4,8(M-Dual), &12.

23. As part of the amendment, staff is replacing the original project's Condition of Certification **TRANS-6**, which required certain mirror movements to mitigate glint and glare impacts, with proposed Condition of Certification **TRANS-7**, which would require a detailed heliostat positioning and monitoring plan.

24. As part of the amendment, staff is proposing a new condition of certification, **TRANS-8**, to require a power tower receiver luminance and monitoring plan.

25. **TRANS-9** requires the owner to secure permits and licenses for the transport of hazardous materials.

Staff has reviewed **Socioeconomics Figure 1**, which shows that there is no minority population within a six-mile buffer of the proposed PSEGS. Therefore, construction and operation of the proposed project would not cause disproportionate direct or cumulative traffic and transportation impacts to an environmental justice population.

PROPOSED CONDITIONS OF CERTIFICATION

Staff has proposed modifications to the Traffic and Transportation Conditions of Certification as shown below. (**Note:** Deleted text is in ~~strikethrough~~, new text is **<u>bold and underlined.</u>**)

In summary, staff has added new conditions for the amendment (**TRANS-5**, **TRANS-6, TRANS-7, and TRANS-8**) which made it necessary to renumber the existing conditions for the original project.

<u>TRANS-1</u>~~**TRANS-1**~~ Prior to the start of construction of the PSEGS, the project owner shall prepare and implement a Traffic Control Plan (TCP) for the PSEGS's construction and operations traffic. The TCP shall address the movement of workers, vehicles, and materials, including arrival and departure schedules and designated workforce and delivery routes.

The project owner shall consult with the County of Riverside and the California Department of Transportation (Caltrans) District 8 office in the preparation and implementation of the Traffic Control Plan (TCP). The project owner shall submit the proposed TCP to the County of Riverside and the Caltrans District 8 office in sufficient time for review and comment, and to the Energy Commission Compliance Project Manager (CPM) for review and approval prior to the proposed start of construction and implementation of the plan. ~~The CPM shall review and approve the TCP or identify any material deficiencies within thirty (30) days of receipt.~~ The project owner shall provide a copy of any written comments from the County of Riverside and the Caltrans District 8 office and any changes to the TCP to the CPM prior to the proposed start of construction.

The Traffic Control Plan (TCP) shall include:

- A work schedule ~~and end-of-shift departure plan~~ designed to ensure that stacking does not occur at intersections necessary to enter and exit the project site~~s~~, **and that LOS at these intersections and on I-10 remains at LOS C or better.** The project owner shall consider using one or more of the following measures designed to prevent stacking: staggered work shifts, off-peak work schedules, and/or restricting travel to and departures from each project site to 10 or fewer vehicles every three minutes ~~during peak travel hours on I-10~~. **The submitted work schedule shall include a detailed plan for worker arrival and departure, including number of workers that are planned to arrive and depart at each time, and methods for ensuring worker compliance.**
- **A plan for monthly monitoring of traffic volume and/or delay and LOS at study roadways and intersections during periods of higher construction employment (Months 19 through 25, including Month 22, the peak construction month).**
- Provisions for an incentive program, such as employer-sponsored commuter checks, to encourage construction workers to carpool and/or use van or bus service.
- Limitation of truck deliveries at the project site to only off-peak **construction commute** hours **and/or staggering of truck deliveries throughout the day**.
- A heavy-haul plan addressing the transport and delivery of heavy and oversized loads requiring permits from the California Department of Transportation (Caltrans) or other state or federal agencies.
- Timing of heavy equipment and building material delivery to the sites
- Parking for workforce and construction vehicles.
- Emergency vehicle access to the project site.
- Provisions for redirection of construction traffic with a flag person as necessary to ensure traffic safety and minimize interruptions to non-construction related traffic flow.
- Placement of signage, lighting, and traffic control devices at the project construction site and laydown areas.
- Placement of signage along northbound Corn Springs Road and at the entrance of each of the I-10 westbound and eastbound off-ramps at Corn Springs Road notifying drivers of construction traffic throughout the duration of the construction period.
- Placement of signage to redirect traffic from Corn Springs Road during construction activities related to roadway realignments and pipeline installation in and across the Corn Springs Road right-of-way.

- Temporary closing of travel lanes, if necessary. **When/if lane closures are required on the State Highway System during construction, refer to Section 517 of Caltrans' Encroachment Permits Manual for the proper procedures to manage traffic during construction. The manual can be accessed online at:**

  http://www.dot.ca.gov/hq/traffops/developserv/permits/

- Access to adjacent residential and commercial property during the construction of all linears.

Verification: At least 60 calendar days prior to the start of construction, including any grading or site remediation on the power plant site or its associated easements, the project owner shall submit the proposed TCP to the County of Riverside and the Caltrans District 8 office for review and comment and to the CPM for review and approval. The project owner shall also provide the CPM with a copy of the transmittal letter to the County of Riverside and the Caltrans District 8 office requesting review and comment.

At least 30 calendar days prior to the start of construction, the project owner shall provide copies of any comment letters received from either the County of Riverside and the Caltrans District 8 office, along with any changes to the proposed Traffic Control Plan, to the CPM for review and approval.

In the MCRs during Months 19 through 25, submit the monitoring results for the study intersections.

TRANS-2~~TRANS-1~~ The project owner shall comply with limitations imposed by Caltrans District 8 and other relevant jurisdictions, including the County of Riverside, on vehicle sizes and weights and driver licensing. In addition, the project owner or its contractor shall obtain necessary transportation permits from Caltrans and all relevant jurisdictions for roadway use.

Verification: In the Monthly Compliance Reports (MCRs), the project owner shall report permits received during that reporting period. In addition, the project owner shall retain copies of permits and supporting documentation on-site for Compliance Project Manager (CPM) inspection if requested.

TRANS-3 The project owner shall **coordinate with Riverside County to conduct pavement testing for all County roadways that could be utilized by PSEGS construction and operation activities. Based on results of the pavement testing and prior to the first heavy haul delivery, the project owner shall make any necessary improvements to ensure the roads provide sufficient load-bearing capacity for construction and operation traffic. Improvements must meet the minimum Riverside County or Caltrans standard (whichever is applicable) for a roadway that accommodates heavy trucks.** ~~restore all public roads, easements, and rights-of-way that have been~~

<u>**Following construction, the project owner shall ensure that any roads**</u> damaged due to project-related construction activities <u>**are restored**</u> to original or near-original condition~~in a timely manner~~, as directed by the CPM <u>**and in coordination with Caltrans and/or Riverside County**</u>. Repair and restoration of access roads may be required at any time during the construction phase of the project to assure <u>**public**</u> safe<u>**ty.**</u> ~~ingress and egress.~~ <u>**Repairs required during construction shall be made as soon as possible.**</u>

<u>**Verification: Prior to site mobilization, the project owner shall provide a copy of the pavement test to the CPM and Riverside County for review. Sixty (60) days prior to start of construction, the project owner shall establish a schedule for approval and completion of any roadway improvements.**</u>

~~At least 30 days prior to the start of mobilization, the project owner shall photograph or videotape all affected public roads, easements, right-of-way segments and/or intersections and shall provide the CPM, the affected local jurisdictions and Caltrans (if applicable) with a copy of these images. The project owner shall rebuild, repair and maintain all public roads, easements, and rights-of-way in a usable condition throughout the construction phase of the project.~~

At least 30 days prior to the start of site mobilization, the project owner shall consult with the County of Riverside and Caltrans District 8 and notify them of the proposed schedule for project construction. The purpose of this notification is to request that the County of Riverside and Caltrans consider postponement of public right-of-way repair or improvement activities in areas affected by project construction until construction is completed, and to coordinate with the project owner regarding any concurrent construction-related activities that are planned or in progress and cannot be postponed.

<u>**During construction, the project owner shall report in the MCRs any project-related damage requiring restoration and the status of that restoration. The MCRs shall be forwarded to Riverside County for review and comment on these activities.**</u>

Within 60 calendar days after completion of construction, the project owner shall meet with the CPM, the County of Riverside, and Caltrans District 8 to identify sections of public right-of-way to be repaired. At that time, the project owner shall establish a schedule to complete the repairs and to receive approval for the action(s). Following completion of any public right-of-way repairs, the project owner shall provide to the CPM letters signed by the County of Riverside and Caltrans District 8 stating their satisfaction with the repairs.

TRANS-4~~**TRANS-5**~~ The project owner or contractor shall comply with Caltrans' and other relevant jurisdictions' limitations for encroachment into public rights-of-way and shall obtain necessary encroachment permits from Caltrans and any other relevant jurisdictions. **Design and construction for the project access road connection to the Corn Springs Road Interchange shall follow the guidelines in Caltrans Highway Design Manual Section 504.8 – Access Control:**

http://www.dot.ca.gov/hq/oppd/hdm/hdmtoc.htm.

Verification: In the MCRs, the project owner shall report permits received during that reporting period. In addition, for at least six months after the start of commercial operation, the project owner shall retain copies of permits and supporting documentation on-site for CPM inspection if requested.

TRANS-5 Federal Aviation Administration Notification of Construction Equipment

The project owner shall file a Form 7460-1 with the Federal Aviation Administration (FAA) regarding the use of any construction equipment exceeding 760 feet in height.

Verification: At least 90 days prior to ground disturbance, the project owner shall submit a copy of the FAA Determination of No Hazard to Navigable Airspace regarding the construction equipment to the CPM.

TRANS-6 Obstruction Marking and Lighting

The project owner shall install obstruction marking and lighting on the two solar power towers. Marking and lighting for the towers shall be consistent with requirements provided in the FAA's "Determination of No Hazard" for the towers, and as expressed in the following documents:

- **FAA Advisory Circular 70/7460-1K, Change 2, Obstruction Marking and Lighting, a med-dual system - Chapters 4,8(M-Dual), &12**
- **FAA Safety Alert for Operators (SAFO) 09007.**

Evening lighting shall use the longest permissible interval between flashes and the shortest flash duration permissible. (See the Biological Resources section for more information.)

Temporary lighting must be installed once a tower reaches 200 feet in height during construction. Permanent lighting consistent with all requirements shall be installed and activated within 5 days of completion of construction and prior to the start of plant operation. Within 5 days after the towers reach their greatest height, an FAA Form 7460-2 "Notice of Actual Construction or Alteration" shall be submitted to the FAA.

Lighting shall be operational 24 hours a day, 7 days a week for the life of project operation. Upgrades to the required lighting configurations, types, location, or duration shall be implemented consistent with any changes to FAA obstruction marking and lighting requirements.

The FAA has proposed publishing guidance on the use of Audio Visual Warning Systems (AVWS) for obstruction lighting. The project owner has the future option to change the tower obstruction lighting system to an Audio Visual Warning System. An AVWS was recommended by the National Park Service in a comment on the FAA Notice of Construction or Alteration for the PSEGS to preserve the natural darkness in this portion of the Mojave Desert. If it is feasible and the project owner wishes to implement an AVWS in the future, the project owner shall consult with the FAA and the CPM as necessary.

Verification: At least 60 days prior to the start of construction, the project owner shall submit to the CPM for approval final design plans for the two solar power towers that depict the required air traffic obstruction marking and lighting, including the temporary lighting.

Within 1 day of the tower heights reaching 200 feet in height, the project owner shall install temporary lighting consistent with FAA requirements and shall inform the CPM in writing (including a photo of the lighting) within 10 days of installation.

Within 5 days of completion of solar power tower construction and prior to the start of plant operation, the project owner shall install and activate permanent obstruction marking and lighting consistent with FAA requirements and shall inform the CPM in writing within 10 days of installation and activation. The project owner shall also provide to the CPM a copy of Form 7460-2 provided to the FAA. The CPM (or designated inspector) shall conduct an inspection after activation to ensure the lighting is operable and has been installed with federal installation and manufacturing standards as established by the FAA under FAA Advisory Circulars.

TRANS-7 Heliostat Positioning and Monitoring Plan

To reduce glint and glare from the project, the project owner shall prepare a Heliostat Positioning and Monitoring Plan (HPMP) which includes the following information. The HPMP shall be implemented during installation of the heliostats and during project operation.

1. Identify the heliostat movements and positions (including during normal operations, daytime mirror-washing, removal of solar flux due to high winds, and all non-normal known operational scenarios and possible malfunctions) that could result in potential exposure of observers at various locations, including pilots, motorists, pedestrians and hikers in nearby wilderness areas, to direct solar reflections from the heliostats (DSRH).

2. Describe within the HPMP how programmed heliostat operation would address potential DSRH events at locations of observers, and how it would maximally limit or avoid potential exposures. This shall include heliostat positioning and transition algorithm exclusion zones that maximally avoid ground-based DSRH events.

3. Describe how the mirrored surfaces of the heliostats would be covered during construction until the heliostats are properly seated, oriented, and under computer control to avoid exclusion zones.

4. Implement a set of baseline heliostat positioning and control algorithms to minimize DSRH events as soon as realistically possible after heliostat installation. The baseline control algorithms shall initially minimize ground-based DSRH events during site set-up, testing and calibration prior to power generation operations. If this does not work to minimize ground-based DSRH events, the project owner shall modify the perimeter fencing along I-10 to prevent motorists from experiencing DSRH events.

5. Prepare a monitoring plan to quantify the frequency and locations of DSRH events and validate that the DSRH events are minimized by HPMP implementation. This may be implemented with a staring camera system along a known line of sight to ground-based observation points (e.g., I-10).

   The monitoring plan shall be made available to interested parties, including the Department of Defense (DoD), California Department of Transportation (Caltrans), California Highway Patrol (CHP), Federal Aviation Administration (FAA), Riverside County Economic Development Agency Department of Aviation, the Riverside County ALUC, and the Riverside County Transportation and Land Management Agency . The monitoring plan shall be updated on an annual basis for the first 5 years and at 2-year intervals thereafter for the life of the project.

6. Obtain field measurements in candela per meters squared and watts per meter squared to validate that the HPMP avoids the potential for human health and safety hazards consistent with the methodologies detailed in the 2010 Sandia Lab document presented by Clifford Ho, et al., including those studies and materials related to ocular damage referenced within.

7. Provide requirements and procedures to document, investigate and resolve legitimate complaints regarding glint and glare events. This includes establishing a toll-free number for the public to report complaints related to glint and glare and posting this number in the same location as that required in Condition of Certification COMPLIANCE-9.

The project owner shall notify the CPM within 3 days of receiving a glint or glare complaint. As soon as the complaint has been resolved or within 10 days of the complaint, the project owner shall submit to the CPM a report in which the complaint(s) as well as the actions taken to resolve the complaint are documented. The report shall include (a) a complaint summary, including the name and address of the complainant; (b) a discussion of the steps taken to investigate the complaint; (c) the reasons supporting a determination of whether or not the complaint is legitimate; and (d) the steps taken to address the complaint and the final results of these efforts. This information shall be included in the Monthly Compliance Reports.

Verification: 60 days prior to the start of construction, the project owner shall prepare and submit to the CPM for review and approval a plan for baseline heliostat positioning and control algorithms to minimize DSRH events after heliostat installation and during site set-up, testing, and calibration. 90 days prior to the start of operation of any unit, the project owner shall submit the remainder of the HPMP describing how the above measures will be implemented to reduce glint and glare during project operation, and how monitoring will occur.

If the project owner receives a complaint regarding glint or glare, the owner shall conduct an investigation to determine whether the complaint is legitimate and if the project is the source of such glint or glare. If it is determined that the project is the source of such glint or glare, the project owner shall take all feasible measures to eliminate or reduce the glint or glare. Such measures may include localized screening.

The project owner shall notify the CPM within 3 days of receiving a glint or glare complaint. As soon as the complaint has been resolved or within 10 days of the complaint, the project owner shall submit to the CPM a report in which the complaint(s) as well as the actions taken to resolve the complaint are documented. The report shall include (a) a complaint summary, including the name and address of the complainant; (b) a discussion of the steps taken to investigate the complaint; (c) the reasons supporting a determination of whether or not the complaint is legitimate; and (d) the steps taken to address the complaint and the final results of these efforts. This information shall be included in the Monthly Compliance Reports.

If no legitimate complaints are received and/or if a legitimate complaint is received and the project owner has resolved the source of the complaint(s) within the first 12 months of project operation, project owner can request that the CPM release the project owner from the obligations under Section 4 of this condition after the 12th month of project operations.

~~**TRANS-6** To reduce glint and glare from the Project, the Project Owner shall implement the following measures during operation of any unit:~~

~~1. Ensure the mirrors are brought out of stowage before sunrise and are aligned to catch the first rays of the morning sun;~~

2. ~~Ensure the mirrors are returned to stow position after sunset;~~

3. ~~As soon as is feasible, redirect malfunctioning mirrors to the east in a manner so that there is no reflection from the sun as the sun continues west; and~~

4. ~~Establish a toll-free number for the public to report complaints related to glint and glare and post such number in the same location as that required in Compliance-9. If the project owner receives a complaint regarding glint or glare it shall investigate to determine whether the complaint is legitimate and if the project is the source of such glint or glare. If it is determined that the project is the source of such glint or glare and the glint or glare is causing human health or safety hazards, the project owner shall take all feasible measures to reduce the glint or glare. Such measures may include localized screening. The project owner shall notify the CPM within 3 days of receiving a glint or glare complaint. As soon as the complaint has been resolved the project owner shall submit to the CPM a report in which the complaint(s) as well as the actions taken to resolve the complaint are documented. The report shall include (a) a complaint summary, including the name and address of the complainant; and (b) a discussion of the steps taken to investigate the complaint, the reasons supporting a determination of whether or not the complaint is legitimate, and the steps taken to address the complaint and the final results of these efforts. In the monthly compliance report, the project owner shall describe any complaints it received that month that it determined not to be legitimate and shall explain the basis of its determination.~~

~~**Verification:**~~ ~~90 days prior to the start of operation of any unit, the project owner shall prepare and submit to the CPM for review and approval a plan describing how the above measures will be implemented to reduce glint and glare. If a legitimate complaint is received concerning potential human health and safety hazards relating to glint or glare, the project owner shall notify the CPM within 3 days of receipt of the complaint and shall provide to the CPM within 10 days of the complaint the report detailing how the complaint has been addressed. . In the monthly compliance report, the project owner shall describe any complaints received that month that were determined not to be legitimate and shall explain the basis of that determination. If no legitimate complaints are received and/or if a legitimate complaint is received and the project owner has resolved the source of the complaint(s) within the first 12 months of project operation, project owner can request that the CPM release the project owner from the obligations under Section 4 of this condition after the 12th month of project operations.~~

TRANS-8 Power Tower Luminance Monitoring Plan

The project owner shall prepare a Power Tower Luminance Monitoring Plan for: providing procedures for conducting periodic monitoring of power tower luminance; and for documenting, investigating, and resolving complaints regarding visual distraction or discomfort glare effects from the power towers experienced by pilots, motorists, and pedestrians.

The Power Tower Luminance Monitoring Plan shall include provisions for the following:

1. Measurement of luminance using an appropriate photometer or similar device and reporting of data in photometric units. The measurements are intended to:

   a) develop a baseline of tower luminance measurements to verify that the luminance values are not in excess of 10^6 cd/m^2 and to support anticipation and investigation of any future visual distraction or discomfort glare events, and to

   b) provide quantitative measures of luminance that can be associated with any observed and reported visual distraction or discomfort glare events/ effects from the power tower receivers;

2. Coordination of luminance evaluations with the FAA, Department of Defense (DoD), Caltrans, California Highway Patrol, Riverside County Economic Development Agency Department of Aviation, Riverside County Transportation and Land Management Agency, and the Riverside County Airport Land Use Commission (ALUC) in relation to the Desert Center and Blythe Airports and I-10. Within 30 days after completing luminance measurements required under this plan, the project owner shall submit a summary report to these agencies for review and comment, and to the CPM for review and approval.

3. Measurement of luminance at locations where any visual distraction or discomfort glare effects have been reported or at a representative site location where accurate measurements of luminance can be made that would be representative of conditions prompting the complaint;

4. Identification and implementation of appropriate mitigation measures if reported visual distraction or discomfort glare events are determined to be legitimate and/ or if power tower luminance is determined to be causing a safety concern. The project owner shall consider and propose any reasonable mitigation measures that are technically and financially feasible. The mitigation measures may include: surface treatment; material or structural changes to increase absorption and reduce reflectivity of the power tower receivers; reduction of the number of heliostats incident on the towers; road signage; screening; or other reasonable measures to either reduce luminance or mitigate the safety concern.

5. Post-mitigation verification. Within 30 days following the implementation of mitigation measures designed to reduce reflectivity of the power towers or mitigate the safety concern, the project owner shall repeat the luminance measurements to demonstrate the effectiveness of mitigation measures and prepare a

supplemental survey report for review and comment by the FAA, Caltrans, California Highway Patrol, Riverside County Economic Development Agency Department of Aviation, and the Riverside County ALUC for review and comment, and to the CPM for review and approval.

Verification: At least 90 days prior to commercial operation of the first PSEGS power plant, the project owner shall provide a Power Tower Luminance Monitoring Plan as described above for review and approval by the CPM. The plan shall require the project owner to report any complaint to the CPM within 10 days of receiving the complaint.

Under the following circumstances, the project owner shall submit to the CPM an evaluation of the effects of the intensity of the luminance of light reflected from the power tower receivers:

A. Within 30 days following commercial operation of each unit;

B. Within 90 days following commercial operation of each unit;

C. After the first 5 years of operation;

D. If a major design change is implemented that results in an increase in the reflective luminance of either power tower; or

E. After receiving a legitimate complaint regarding visual distraction or discomfort glare associated with the power towers.

TRANS-9~~TRANS-2~~ The project owner shall ensure that permits and/or licenses are secured from the California Highway Patrol and Caltrans for the transport of hazardous materials.

Verification: In the MCRs, the project owner shall report permits and/or licenses for hazardous substance transportation received during that reporting period. In addition, the project owner shall retain copies of permits, licenses, and supporting documentation on-site for CPM inspection if requested.

APPENDIX TT1 –
VISUAL SAFETY IMPACT ASSESSMENT

Testimony of Gregg Irvin, Ph.D.

This appendix provides an assessment of potential retinal damage and glint and glare impacts from the proposed Palen Solar Electric Generating System (PSEGS). Specifically, staff assessed the project's potential to cause retinal damage and temporary visual discomfort and disability to nearby viewers.

RETINAL DAMAGE

The ability of light to cause injury to the retina has been shown both clinically and experimentally. Light can result in retinal damage through photothermal, photomechanical, and photochemical mechanisms.

Photothermal damage is the physical damage to the retina that can occur from high levels of irradiance. Irradiance is the density of radiation on a given surface. Well-established standards are provided by the American National Standards Institute (ANSI, Z136.1-2000) for protection of the human eye from photic exposure.

Photomechanical damage is mediated by an acoustic process and is associated with high energy pulses of extremely short duration, such as a pulsed laser exposure. Photomechanical damage mechanisms are not relevant to the Palen Solar Electric Generating System (PSEGS).

Photochemical damage is associated with both long-duration exposure times as well as lower-wavelength (higher-energy) light exposure. While retina pigment epithelium (RPE) and the neurosensory retina are protected from light-induced exposure by the absorption profile of the surrounding ocular structures (e.g., cornea, crystalline lens, macular pigments) as well as through retinal photoreceptor outer segment regeneration, photic injury is still quite possible due to photochemical retinal light toxicity mechanisms. Photochemical injury is both dose dependent and cumulative in nature. This has significant implications for observers (such as workers on site) that spend a significant amount of time in proximity to the high luminance solar field in the additional presence of high ambient (existing) luminance characteristic of a desert environment. As retinal injury can be caused by exposure to otherwise innocuous visible light, there appears to be some critical dose or threshold at which exposure becomes injurious. The safe exposure times for common ophthalmic instruments (e.g., fundal photography) has been reported in the literature and supports the concept of a critical threshold dose necessary for injury.

For the current project, both photothermal and photochemical mechanisms are relevant.

PHOTOTHERMAL RETINAL DAMAGE

Photothermal retinal damage occurs when the eye is exposed to sufficient light energy to heat the retina to a point where damage occurs, resulting in a permanent blind spot. Because the eye is an optical focusing system, the energy at the retinal surface is concentrated by as much as a factor of 100,000. The ocular impact on an observer from either the heliostats or the solar receiver steam generators (SRSGs) is calculated as the retinal irradiance (Er). The calculation of Er takes into consideration the size of the light emitting object (SRSG or heliostat), the intensity in W/m^2 (irradiance) at the observer location, and the vulnerability of the human eye.

The level of exposure which is considered as the limit between safe and harmful is called Maximum Permissible Exposure (MPE) limit. The MPE that can be tolerated by the human eye is an industry standard and is defined by Sliney and Freasier & el. The MPE is defined for two exposure condition types: momentary exposure, correlated with the human blinking instinct, and continuous exposure.

- MPE for a momentary exposure (0.15 s) is 1 W/cm^2 = 10,000 W/m^2.
- MPE for continuous exposure is 0.1 W/cm^2 = 1,000 W/m^2.

Motorists

During normal operation, only the focal area of the SRSG, which is approximately 20 by 20 meters, will receive concentrations of solar radiation. Locations on the ground and areas surrounding the footprint of the plant will not receive solar radiation concentrations above that of direct sunlight. Therefore, in normal plant operation, there is no potential for any plant-sourced solar radiation exposure hazard to motorists outside the boundary of the project.

The intensity of light emitted from the SRSG is 70 W/m^2. Using a conservative approach, the intensity at the observer's location can be assumed to equal the intensity at the source. For comparison, the intensity of visible light from the sun is 80,000 W/m^2 at the retina and the Maximum Permitted Exposure at the retina is 1,000 W/m^2, assuming continuous exposure.

The shortest distance between a PSEGS SRSG and a passing I-10 motorist is 4,265 feet, or 1,300 meters. The SRSG diameter is approximately 100 feet. Therefore, the subtended angle is 23 mrad (milliradians) or 1.33 degrees.

When an illuminated object subtends an angle of 23 mrad to the viewer's eye, the retinal irradiance threshold for damage is greater than 40,000 W/m^2. Thus, since the light intensity from the SRSG is no greater than 70 W/m2 at any point of observation along I-10, there is no potential for photothermal damage from the SRSG to I-10 motorists.

The same calculation for retinal irradiance from the SRSG can be used for heliostats. Using a ray tracing method, the amount of light concentration at given distances from a given heliostat was calculated. The light concentration at a given distance is dependent upon the heliostat focal length, and three different heliostat focal lengths at PSEGS were used to calculate the safe retinal irradiance for increasing distances. The results demonstrated that there is no possibility for photothermal retinal damage to I-10 motorists from the solar field. Further, the only possible risk is when standing on the tower and having a direct solar reflection from a heliostat within 200 meters. This operational hazard will be mitigated with appropriate safety procedures and guidelines for on-site personnel.

Motorists outside the plant boundaries will not be exposed to retinal irradiance (Er) levels beyond the maximum permissible exposure (MPE) and will not experience photothermal retinal damage. Staff concludes that there is no risk for photothermal retinal damage to motorists or ground-based observers.

Pilots

The heliostats are designed to reflect sunlight toward the SRSG at the top of the tower. For normal operation, the heliostats will orient themselves according to their position in the field, day of the year, and time of day in order to reflect the sun's rays either onto the SRSG ("tracking" orientation) or onto an area nearby (standby orientation, when the heliostats are focused far enough from the tower and SRSG to free them from radiation but close enough to allow the heliostats to quickly enter tracking mode). In the standby position, the heliostats reflect sunlight back into the sky where the potential exists for the heliostat 'beam' to intercept aircraft.

The size of the PSEGS site as defined by Federal Aviation Administration (FAA) regulations is the volume that encompasses the perimeter of the site up to a height of 500 feet above the tower. This imaginary volumetric body is the control volume that the heliostat tracking system takes under consideration. Within this volume, the heliostats are programmed to concentrate flux in certain positions that will cause the flux leaving the imaginary control volume to scatter to a level that will cause no retinal damage to pilots. The control system is designed so that solar flux will not exceed the momentary MPE (10 kW/m^2) outside and above this control volume.

Staff concludes that there is no risk for photothermal retinal damage to pilots.

PSEGS Site Workers

Sandia researchers found that retinal irradiance from single heliostat beams exceeded the safe limits only within a short range (up to 40 meters [131 feet]) within the focal distance of the heliostat. This is true for both the Solar One facility and the Ivanpah Solar Electric Generating System (ISEGS). For heliostats with focal distances greater than 270 meters (886 feet), safe retinal limits were never exceeded (Ho, 2011). The levels of irradiance that exceed the safe limit are only associated with heliostats that have a focal distance of 270 meters (886 feet) or less, and the limits are only exceeded within ±20 meters (66 feet) of that focal length. In other words, the maximum distance where the limits may be exceeded from the PSEGS is 290 meters, or 951 feet, even when assuming worst case conditions for all parameters. Thus, levels of irradiance may only be exceeded within 951 feet of the facility's heliostats that have focal lengths of less than 270 meters (886 feet). These heliostats are in the solar field near the tower. This area where levels of irradiance may exceed the safe limits would not include any ground-based observer outside the project perimeter fence or any airspace that any pilot would be legally allowed to fly in near the power tower. The project owner's risk mitigation plans include a prevention program with safety precautions and guidelines for maintenance, monitoring, and employee training measures to insure eye protection under these rare conditions of exposure. The workers would be trained to take appropriate safety precautions when working onsite during power operations, including use of appropriate eye protection. See the **WORKER SAFETY AND FIRE PROTECTION** section's conditions of certification, which require workers to wear protective eyewear.

PHOTOCHEMICAL RETINAL DAMAGE

Photochemical damage is associated with long-duration exposure times as well as lower-wavelength (higher-energy) light exposure. While retina pigment epithelium (RPE) and the neurosensory retina are protected from light-induced exposure by the absorption profile of the surrounding ocular structures (e.g., cornea, crystalline lens, macular pigments) and through retinal photoreceptor outer segment regeneration, photic injury is still possible due to photochemical retinal light toxicity mechanisms.

Photochemical injury is both dose-dependent and cumulative in nature (Irvin and Ramer, 1988). The cumulative time-dependent nature is that daily exposures can build up and can last many weeks. For example, it has been estimated that the half-life (1/e, when an exposure effect has decayed to approximately 37%) of the cumulative dose exposure effect is on the order of 30 days. This has significant implications for observers that spend a significant amount of time in proximity to the high luminance environment of a solar field in the presence of the additional high terrestrial ambient of the desert environment.

As retinal injury can be caused by exposure to otherwise innocuous visible light, there appears to be some critical dose or threshold at which exposure becomes injurious. The safe exposure times for common ophthalmic instruments (e.g., fundal photography) has been reported in the literature and supports the concept of a critical threshold dose necessary for injury.

Staff agrees with the project owner that the potential for photochemical retinal damage to motorists and pilots given the cumulative exposure effects of the combined terrestrial ambient and solar field/ tower exposure levels is not significant. At these distances and because these individuals will not experience long duration exposure, there is no risk for photochemical damage.

When evaluating the implications of photochemical effects for on-site workers in proximity to the towers or the heliostats, it must be noted that the effect is directly related to the ambient (background) light conditions. The PSEGS is located in a bright desert environment thereby increasing the potential chance for photochemical retinal damage. The cumulative daily exposure to workers to the ambient environment combined with the additional potential cumulative effects of heliostat and SRSG exposure puts project workers at risk for photochemical retinal damage. This is due to the cumulative nature of photochemical effects. Thus, to ensure the safety of the workers and others within the project boundaries, personal protection equipment (PPE) in the form of protective glasses will be provided as required in the **Worker Safety and Fire Protection** conditions of certification. Protective glasses have been developed for workers engaged in intense solar field work, tower work, and intense close viewing of the SRSG.

There is precedence for the issuance of special safety glasses. For example, they have been issued to the operators at Solar Energy Development Center (SEDC) and at the Coalinga and ISEGS solar thermal plants. The potential photochemical retinal hazards are calculated according to IEC 62471 standard (same as CIE S 009: 2002), titled: "*Photobiological Safety of Lamps and Lamp Systems*", where the spectral values were taken from "ASTM G173-03 Reference Spectra Derived from SMARTS v. 2.9.2 (AM1.5)" and are the same as the "ISO 9845-1-1992." Based on these standards, the project owner has identified appropriate PPE in the form of specialty safety glasses (sunglasses) for workers engaged in intense solar field work, tower work, and intense close viewing of the SRSG. **Worker Safety and Fire Protection** staff has included conditions of certification requiring that workers wear the appropriate specialty safety glasses. (See Condition of Certification **WORKER SAFETY-1** (Project Construction Safety and Health Program) and **WORKER SAFETY-2** (Project Operations and Maintenance Safety and Health Program).

GLINT AND GLARE

Glare is considered as difficulty seeing in the presence of bright light, including direct or reflected sunlight or artificial light such as car headlamps at night. Glare is generally defined as a continuous/ sustained source of excessive brightness relative to the ambient lighting. In contrast, glint is considered as difficulty seeing in the presence of a transient bright light source and is generally considered to be intermittent. A glint effect would be, for example, brief reflections of sky or sunlight from one of the heliostats while driving by. A glare effect is more sustained, such as might be present from the sustained reflections from the tower SRSGs. The heliostats can be a source of glint (e.g., from direct solar reflections from the heliostats (DSRH) and a source of sustained glare (e.g., from reflections of the sky background). The tower SRSGs can be a sustained source of glare.

Glint and glare are measured both in terms of the potential for physiological effects and for psychological effects. Physiological effects involve the potential for light to adversely affect the retina of viewers and other parts of the eye through photothermal and photochemical damage. This potential is evaluated in units of watts or kilowatts per square meter (W/m^2 or kW/m^2) and is generally referred to as irradiance. (See the earlier discussion of photothermal and photochemical damage.) Psychological effects, referred to as glint, glare and perceived brightness, are considered in terms of luminance, evaluated in units of candelas per square meter (cd/m^2).

Perceived brightness, as well as glint and glare effects, depends on a variety of factors, including the global ambient luminance, target size, retinal location, and the relationship between the luminance of the target and background. The global ambient luminance, or background luminance, sets the state of visual adaptation and hence the spatial and temporal processing characteristics of the human visual system. Within this context, perceived brightness depends critically on the luminance relationship and sizes of the target (SRSGs receivers and/or heliostats) and background (sky or terrain, mainly terrain at the Palen site).

Glare is caused by a significant ratio of luminance between the task (that which is being looked at) and the glare source. Factors such as the angle between the task and the glare source and eye adaptation significantly influence the experience of glare. In the 1920's, researchers (Luckiesh and Holladay 1925, Stiles, 1929) independently proposed that illumination conditions can produce two different types of glare effects: discomfort glare and disability glare. Today, glare is still generally divided into these two class types.

Discomfort glare results in an instinctive desire to look away from a bright light source, or difficulty in seeing a task. Discomfort glare is a negative subjective reaction to the presence of a glare condition. Whether or not discomfort glare affects visual performance and/ or task performance depends critically on the nature and difficulty of the task to be performed. Discomfort glare, as any visual stimulus of significant luminance, transiently desensitizes the retina locally and can produce afterimages. Discomfort glare generally occurs when luminance contrast values become large enough to elicit a psychological response, a sensation of annoyance. Although studied fairly extensively, discomfort glare has not been sufficiently quantified to provide an accurate predictive capability. It is relatively easy to elicit a discomfort glare response. However, establishing a reliable objective correlate and predictive capability remains elusive.

Disability glare renders the task impossible to view, such as when driving westward at sunset. Disability glare is generally caused by the intraocular reflection of light within the eye, a scattering effect which can mask parts of the visual field and reduces the local contrast between task (that which is being observed, the target fixated) and glare source to the point where the task cannot be resolved or distinguished. Detailed quantitative studies have investigated disability glare (Vos, 1984) and the phenomena appears to be reasonably well understood. While the cause of disability glare is fairly well known, discomfort glare is less well understood. Further, there are no standards or agreed upon methodologies for assessing disability glare, especially in daylight conditions (Berman, 1993).

Staff recognizes that definitive standards for the safety effects of glint and glare, from distraction to discomfort to disability, do not exist. Although a variety of organizations, including the vision research community, academia, the National Highway Traffic Safety Administration (NHTSA) and the US Air Force have conducted research on various aspects of deleterious effects of glint and glare, there is currently no accepted standard for assessing, measuring, or limiting the distraction, discomfort, or disability effects of glint and glare. Essentially, there is no consensus in the research regarding thresholds for onset of glint and glare effects and there are no reliable metrics for determining the glint and glare thresholds for a significant impact to traffic and transportation.

GLINT AND GLARE FROM THE HELIOSTATS

The project owner has demonstrated through current and prior modeling for the Hidden Hills and Rio Mesa projects that heliostat retinal irradiance and beam intensity (under worst-case conditions) is eye safe and would not cause retinal damage. The heliostats are designed to reflect sunlight toward the SRSG at the top of the tower and are programmed such that reflectivity would rarely be directed toward ground-level viewers located outside of the project site during power generation operations. Staff is not concerned that exposures in excess of MPE would occur. This issue has been dealt with comprehensively and thoroughly by the project owner and by the **Worker Safety and Fire Protection** conditions of certification, and permanent retinal damage effects are not a concern. The concern is for visual effects below the MPE where it is uncertain what the impacts of glint and glare would be to both ground-based and airborne observers.

When observed from a distance during operations, the heliostat fields would generally reflect a portion of the sky to the viewer. In the distal field regions (to the far right and left of the towers) the appearance would be somewhat like a body of blue water. In the region closer to the tower, the heliostats would often reflect a portion of the sky in greater proximity to the sun, and these regions would appear brighter and whiter, producing a low to moderate level of sustained glare depending on viewing geometry and range. Staff considers these signatures, although salient, as not significant. The visual signatures from indirect reflections from the heliostats, even in great numbers, are considered as rather benign.

However, this is not the case for DSRH. DSRH occur when the sun's image is reflected directly into the observers view.

DIRECT SOLAR REFLECTIONS FROM THE HELIOSTATS (DSRH)

The project owner provided luminance data for DSRH as a function of range and heliostat focal length. At Palen, three populations of heliostats are used, with focal lengths of 250, 450 and 1,000 meters. The heliostats with focal lengths of 450 and 1,000 meters have luminance values greater than 75 percent of the sun (1,250,000,000 cd/m^2) for all viewing distances greater than 400 meters and out to a distance well in excess of 2,000 meters. The glint (from a transient exposure) or glare (from a more sustained exposure) from a single heliostat at this luminance level causes fairly extensive intra-ocular scattering. The minimum luminance across all distances and heliostat focal distances for direct solar reflection is 400,000,000 cd/m^2. (Note: For comparison, the luminance of the clear sky at noon is about 5,000 to 10,000 cd/m^2). DSRH events observed at ISEGS produced total visual occlusions on the order of 3 degrees of the central visual field and extensive visual interference on the order of 10 degrees. At a minimum, DSRH are considered as being at a discomfort level and all reasonable actions should be taken to mitigate these events during site construction, testing and operations. DSRH could also potentially be disabling for motorists.

DSRH are judged to be in excess of the threshold for discomfort glare for viewing distances up to at least 10 miles (based on empirical observations at ISEGS SEGS, 07/08/2013). DSRH can occur at ground level for motorists on I-10 and State Route 177, at Joshua Tree National Park, at the Palen McCoy and Chuckwalla Mountains Wilderness areas, and at a variety of locations where human observers and operators will be present.

Given the visual impact of DSRH events, staff believes they must be reasonably mitigated to a minimum during the construction phase, during initial start-up, which includes heliostat calibrations and operational testing, and during standard power generation operations. Relying exclusively on trained employee observers and citizen self-report mechanisms to access the frequency and severity of DSRH for ground-based receptors is considered as insufficient for providing robust monitoring and subsequent mitigation procedures.

Condition of Certification **TRANS-7** Heliostat Positioning and Monitoring Plan is proposed, which includes procedures and methodologies for the quantification and minimization of DSRH events during construction, testing and operations. **TRANS-7** would provide empirical feedback as to the frequency of events, the efficacy of the heliostat control algorithms, and data for the improvement of the heliostat control algorithms. Staff concludes that with appropriate modeling of ground-based receptor locations and heliostat control, steering and monitoring algorithms, the frequency of ground-based DSRH events can be mitigated to a realistic minimum.

An additional glint and glare concern from the heliostats is for aircraft. As for ground-based observers, staff considers the indirect sky reflections from the heliostats to be salient but not significant for pilots. The most significant airborne events from the heliostats would be DSRH events. Impacts to airborne receptors cannot be mitigated to the same extent as impacts to ground-based receptors. Airborne DSRH events are considered inevitable and their frequency and severity would depend on the frequency, range and geometry of airborne events in the area. The ability to obtain and account for the presence, range, location and time of aircraft transits in the area is not realistically achievable. Furthermore, direct solar reflections are common and expected events for pilots. They commonly occur from reflections over lakes and streams as well from reflections from man-made objects such as metal roofing. Pilots are generally very adept at dealing with such events, and individual or sequential DSRH events are not considered as inducing severe discomfort or compromising pilot visual or control performance.

Locations on the ground, areas surrounding the footprint of the plant, and the surrounding airspace would not receive solar radiation concentrations above that of direct sunlight. Significant precautionary measures are planned for incorporation into the anticipated heliostat control algorithms. The guidelines for these measures are detailed in **TRANS-7**.

With currently available information, staff estimates that glint and glare effects from the heliostats may cause some mild discomfort to pilots but should not be considered as significant discomfort or disability glare.

GLARE FROM THE SRSGS

During operation, the tower SRSGs would produce a sustained bright source of reflected light from the heliostats. Because the SRSGs are ‘circular’ (wrapping around the tower 360 degrees) and near the peaks of the solar towers, they would be highly visible from most vantage points and for many miles. There is no doubt that the tower SRSGs would result in a prominent and sustained visual effect. The issue from a Traffic and Transportation perspective is: Will the SRSGs produce sufficient glare and/or excessive perceived brightness to result in discomfort glare, disability glare and/or compromised operator performance for motorists or pilots? As discussed previously, glint and glare effects and the associated perceived brightness depend on a variety of factors, including the state of visual adaptation, source size, and target to background contrast. Within this context, perceived brightness depends critically on the luminance relationship and sizes of the target (SRSG) and background (sky or terrain). Also, it is very difficult to predict perceived brightness from luminance alone, especially at the substantially high levels under consideration.

The irradiance of the sun is enormous, on the order of 80,000 W/m^2. As such, the luminance of the sun is also enormous and on the order of $1.6x10^9$ cd/m^2 (clear sky at noon). The luminance of the tower SRSGs is anticipated to be much lower, on the order of $1x10^6$ cd/m^2, and the worst case maximum irradiance is estimated to be 70 W/m^2. Furthermore, since luminance does not decrease much with distance, the conservative assumption has been made that luminance stays constant. Although the SRSGs would be lower in luminance (1,000,000 cd/m^2) than the sun, this is still a very high luminance level in comparison with the brightest sky, which would be approximately 8,000 cd/m^2. Also, at PSEGS, the towers would generally be viewed with the mountains in the background, rather than the sky, further elevating the target/ background contrast level. Thus, the contrast ratio for the towers could range from 125:1 (sky background) to roughly 1,000:1 (mountain background at 1,000 cd/m^2). At these contrast ratios, the SRSGs would appear very bright, salient, and visually distracting (commanding visual attention and eliciting fixation) but the visual effect is anticipated to be less than that which would produce discomfort glare.

Perceived brightness, like visual spatial integration, is dependent on system spatial resolution. For target sizes in excess of the spatial integration limit (i.e., daytime acuity levels) brightness remains relatively constant as a function of viewing distance. As the limits of acuity are approached (in our case due to increasing viewing distance), brightness falls off and transitions to a relationship in which brightness is proportional to distance. Thus, at large viewing distances, the perceived brightness of the SRSGs would decrease substantially despite a relatively small change in luminance (due to atmospheric attenuation). It is estimated that by 10 miles, when the SRSG visual subtense is 0.1 degrees, this transition would be well in process and the tower brightness would be falling off substantially.

Staff concludes that at a maximum luminance of $1x10^6$ cd/m^2 and in the visual context of the PSEGS site, the tower SRSGs would not be a source of discomfort or disability glare from a practical and operational perspective. Arguably and clearly, the sun is a source of disability glare. If a person stares directly at the sun, visual function is severely degraded and visually-based performance is severely limited. However, one rarely hears complaints about the sun in this regard. The simple reason for this is that normally people do not fixate on or look at the sun directly for any length of time. In general, a single 100-150 msec fixation is sufficient for an aversion reaction to look elsewhere (and sufficient for a fairly prominent after-image). The limited times in which the sun can be a source of disability glare are under conditions when visual performance requires a gaze in close proximity to the sun’s location. This would occur, for example, when driving west into the sunset when visual monitoring of the road requires viewing gazes near the sun’s visual location.

Staff thinks that a similar situation exists for the tower SRSGs, albeit to a lesser extent given the significantly lower tower luminance. Due to their anticipated perceived brightness based on the luminance of the towers during nominal operations, it is anticipated that observers would not look directly at the tower SRSGs for more than a single fixation (or several separate fixations due to tower novelty) before averting their gaze to an alternate location. Additionally, because the forward line of site for motorists on I-10 in proximity to the PSEGS field is looking forward either eastward or westward and the two SRSGs are to the north, it would not be necessary to gaze in close proximity to the towers. As such, observers would tend to preserve their visual function (much as they do with the sun) and the tower SRSGs would not functionally be a source of discomfort or disability glare.

It should be noted that glare is generally considered as a scattering effect in the eye, although any optical interface can also add to perceived glare, such as glasses, automotive windshields and aircraft canopies. Scattering in the human eye increases as a function of age (Sliney and Freasier, 1972). Glare-related scatter effects remain nearly constant as a function of age until 40-45 years, when scatter rises exponentially and triples by the age of 60. As such, any glare effects produced by the SRSGs may be more pronounced in the aging population.

Staff considers the glare effects from the tower SRSG receivers as significant from a visual perspective (salience, distraction, prominence) and unmitigable while maintaining effective plant operations. The brightness of the SRSGs would be clearly visible and prominent. The extent to which the visual signature (either from a brightness or glare perspective) would be distracting remains unclear. However, staff concludes that the sustained glare from the SRSGs during nominal operating conditions would not be significant and not produce discomfort or disability glare to the extent of producing a safety hazard from an operator control perspective (e.g., driving a vehicle, flying a plane).

This conclusion is based on the project owner's calculations that the SRSGs would not exceed a luminance of 1×10^6 cd/m^2 under any operating or viewing conditions. Given the uncertainty of the particular viewing conditions and methodologies for establishing the conditions under which discomfort and/or disability glare would occur, a Condition of Certification is proposed to monitor the tower SRSGs's luminance over time. The intent of **TRANS-8** is to periodically monitor the luminance of tower SRSGs to ensure that they are within the stated maximum luminance values and therefore would not create a safety hazard for pilots, motorists, and recreation users. This includes enacting appropriate monitoring procedures to verify performance over time, establishing procedures for addressing any complaints regarding visual distraction or discomfort glare effects from the power towers, and training project operating and maintenance personnel to quickly identify and address potential glare-related safety issues.

CONCLUSIONS

1. Staff concludes that there is no risk for photothermal retinal damage to motorists, pilots or the general civilian population outside of the PSEGS site from either the heliostats or tower SRSGs. Workers within the site boundaries could rarely experience exposures (from the subset of heliostats with 270 meter focal lengths and over a very narrow range of distances) at or slightly above MPE. Staff concludes that planned safety precautions, worker training and use of protective eyewear as required in the **Worker Safety and Fire Protection** conditions mitigates this risk to less than significant.

2. Staff concludes that there is no risk for photochemical retinal damage to motorists, pilots or the general civilian population outside of the PSEGS site from either the heliostats or tower SRSGs. However, workers on site (engaged in intense solar field work, tower work, and intense close viewing of the SRSG) are at risk of photochemical retinal damage. The provision of personal protection equipment (PPE) in the form of protective glasses (sunglasses) is adequate to provide an additional margin of safety regarding any potential effects of photochemical retinal damage. (See Conditions of Certification **WORKER SAFETY-1** Project Construction Safety and Health Program and **WORKER SAFETY-2** Project Operations and Maintenance Safety and Health Program.)

3. Staff concludes that sky reflections from the heliostat fields, although inevitable and salient, are not a source of significant visual discomfort glare. However, DSRH (even single heliostat events) are significant and a source of discomfort glint and glare, and potentially of visual disability glint and glare. Staff concludes that if appropriately implemented, Condition of Certification **TRANS-7** Heliostat Positioning and Monitoring Plan will minimize the frequency of DSRH events during the testing, calibration and operational phases of the PSEGS to a non-significant level.

4. Staff concludes that the sustained glare from the SRSGs during nominal operating conditions (at a maximum of $1x10^6$ cd/m^2) would not produce discomfort or disability glare that would interfere with motorists' or pilots' operation of their vehicles, and would therefore not result in significant traffic and transportation impacts. This glare would be significant from a visual resources perspective, however. Higher luminance levels could cause significant traffic and transportation impacts as well. Proposed Condition of Certification **TRANS-8** Power Tower Receiver Luminance and Monitoring Plan provides procedures and methodologies for the identification and mitigation of visual distraction effects and discomfort glare or disability glare effects with the potential of causing a safety concern. This condition would ensure that luminance would remain at $1x10^6$ cd/m^2 or less.

APPENDIX TT2 –
Risk of Impacts to Vehicle Operators Driving on Interstate-10 Due to Glint and Glare Associated with the Palen Solar Electric Generating System

Testimony of Alvin Greenberg, Ph.D., QEP, Geoff Lesh, PE, CSP, Gregg Irvin, Ph.D.

SUMMARY OF CONCLUSIONS

Staff has conducted an assessment of the chances that glint and glare coming from the proposed Palen Solar Electrical Generating Station (PSEGS) could disrupt a person's vision enough so as to interfere with driving a vehicle on nearby Interstate-10 (I-10), thus causing accidents on the highway. Staff analyzed two scenarios: diffuse glint and glare coming from the proper operating of the system and direct light coming from a malfunctioning or misoriented heliostat (mirror) pointing directly at the highway. Staff found that based upon a qualitative analysis, it is implausible that glint and glare under normal operating conditions could cause vehicular accidents on I-10. Therefore, staff concludes that the risk of glint or glare causing impairment of vehicle operators on I-10 is less than significant.

However, if a heliostat during construction or operations were to be oriented even for a few seconds facing the interstate such that drivers would experience a direct reflection from the heliostat within their field of vision, staff found based upon a quantitative risk assessment that significant visual impairment (flash blindness or impairing glare) could occur and result in a vehicular accident. Therefore, staff concludes that, in this specific scenario, the risk of direct glare from an improperly-oriented heliostat causing impairment of vehicle operators on I-10 is significant and requires mitigation.

Since the likelihood of heliostat orientation failure would be remote during operations but highly probable during construction, staff recommends that the project owner be required to implement appropriate mitigation procedures. These could include covering the mirrored surfaces of the heliostats during construction until they are properly seated, oriented, and under computer control and/or implementing early heliostat computer control algorithms to establish exclusion zones which could result in direct reflections to ground based observers.

BACKGROUND

Palen Solar Holdings, LLC (PSH) has filed a petition with the Energy Commission requesting to modify the Palen Solar Power Project (PSPP), now called PSEGS (Palen 2012a). The major modification involves replacing the parabolic trough solar collection system with Bright Source's solar tower technology. Two adjacent solar fields producing 250 MW each are proposed for a combined nominal output of approximately 500 MW. Heliostats - elevated mirrors mounted on a pylon guided by a tracking system - focus the sun's rays on a solar receiver steam generator (SRSG) located atop a 750-foot tower near the center of each of the two solar fields to create steam to drive a turbine generator that provides electricity.

Because the PSEGS project involves the use of mirrors (heliostats) to direct reflected sunlight at power tower receivers, the potential exists for glare or glint to be observed by nearby viewers, including motorists on the adjacent interstate. The heliostats can be a source of glint for direct solar reflections and a source of sustained glare for reflections of the sun and sky background.

The location of the power plant very near Interstate-10 (an east-west regional arterial with fully approved freeway status and a speed limit of 70 mph) has raised concerns over the impact light reflected from the heliostats (referred to as glint and glare) might have on driver's ability to see the road clearly when in the vicinity of the PSEGS. The distance between this heavily-traveled Interstate Highway and large numbers of heliostats will be as little as a few hundred feet for a considerable distance along the highway. It is well known that glare from a rising or setting sun directly in-line with traffic flows can visually impair drivers to the point of causing temporary inability to see the road in front, thus resulting in vehicular accidents. The National Highway Traffic Safety Administration estimated that glare accounted for about 16 percent of the environment-related crashes in the U.S. between 2005 and 2007 (NHTSA 2008) and the State of Nebraska estimated that during 2002–2009, there was an average of one sun glare-related motor vehicle crash per day (Nebraska Crash Outcome Data Evaluation System 2011).

During normal operation, only the focal area near the top of each 750-ft. solar tower will receive high concentrations of solar radiation from thousands of heliostats. Locations on the ground and areas surrounding the footprint of the plant will not receive reflected solar radiation concentrations above that of direct sunlight. Therefore, in normal plant operation, there is little potential for any direct-focused solar radiation exposure hazard to motorists outside the boundary of the project. PSEGS's Unit 2 is closest to Interstate I-10 and the Unit 2 tower is approximately 1,368 meters (4,488 feet) from the highway. At this distance, there is no potential for retinal damage due to gazing at the SRSG (CEC 2013r).

Because the PSEGS project involves the use of mirrors (heliostats) to direct reflected sunlight at power tower SRSG, the potential exists for glare or glint to be observed by nearby viewers, including motorists on the adjacent roadway. The heliostats can be a source of glint for direct solar reflections and a source of sustained glare for reflections of the sun and sky background. The geometric arrangement of the solar array orients the mirrored face of each heliostat towards the central receiving tower. Each heliostat has a motorized computer controlled positioning system that positions each mirror to focus its reflected energy on the receiver at the top of the central receiving tower.

After a thorough review of the scientific literature – including the review of over 24 scientific studies and reports and over a dozen other studies found only on internet sites -- staff learned that definitive safety standards that would protect people from the effects of glint and glare (ranging from distraction to discomfort to disability) do not exist. Although a variety of organizations including the vision research community, academia, the National Highway Traffic Safety Administration (NHTSA) and the U.S. Air Force have conducted research on various aspects of deleterious effects of glint and glare, there is currently no accepted quantitative standard for assessing, measuring, or limiting the distraction, discomfort, or disability effects of glint and glare. There is essentially no scientific or regulatory consensus regarding thresholds for onset of glint and glare effects that fall short of permanent eye damage and there are no reliable metrics for determining the glint and glare thresholds for a significant impact to traffic and transportation. Therefore, absent a no-effects threshold standard or even a lowest observable effects level, staff was unable to conduct a quantitative risk assessment and instead performed a qualitative study based upon safety metrics established for prevention of permanent eye damage relative to exposure angles and distances of the proposed solar facility. In this manner, staff used a risk assessment metric of simply "Yes" or "No" chances for impacts.

Appendix TT2 Figure 1 (Source: Palen 2012a, Fig. 2.1-5) depicts the proposed solar power plant layout and its proximity to I-10. **Appendix TT2 Figure 2** (Adapted from Palen 2012a) is an enlargement of the field closest to Interstate 10. **Appendix TT2 Figure 3** (Source: Palen 2012a) shows the alignment of Interstate 10 at greater distance from the solar field.

Purpose and Methodology

The purpose of this risk assessment is to evaluate the risk associated with vehicular operator impairment due to glint or glare resulting from the proposed Palen Solar Electric Generating Facility (PSEGS) and to evaluate the potential risk of vehicular accidents that such impairment could cause. According to Clifford Ho, a leading researcher and spokesman on this subject, "solar glare caused by reflections from solar energy installations can occur at varying times in unexpected locations….. [Both glint and glare] can result from reflections of light on solar energy components such as PV modules, concentrating solar collectors/mirrors and receivers" (Ho 2013, Page 1).

A second purpose is to evaluate the potential for disability glare due to a malfunction of a heliostat producing direct reflection of light onto traffic on I-10. This effect can be quantitatively assessed by use of a Daylight Glare Index (DGI).

Staff analyzed two scenarios: diffuse glare coming from the proper operating of the system and direct disability glare (sometimes referred to as veiling glare) coming from a malfunctioning or misoriented heliostat pointing directly at the highway.

Strong specular reflection of sunlight (defined as the mirror-like reflection from a surface in which light from a single incoming direction is reflected into a single outgoing direction as opposed to diffuse reflection where incoming light is reflected in all directions) from a smooth surface is often referred to as glint. Glint causes difficulty seeing in the presence of a transient bright light source and is generally considered to be intermittent. A glint effect would be, for example, brief reflections of sky or sunlight from one of the heliostats while driving by. Glare has been defined as the reflection of a bright light source such as the sky around the sun. A glare effect is more sustained, such as might be present from the sustained reflections from the Solar Recovery Steam Generators (SRSGs) located at the top of each tower. However, definitions of glint and glare are not consistent in the literature, and either can be characterized as transitory or continuous. Whatever term is used, the effect of glint or glare in the context of assessing risk to drivers occurs in the presence of an offending light source that disrupts the field of vision thereby compromising the driving task. This is typically referred to as disability glare.

Glare is a disturbance of visual acuity or complete disruption of vision resulting from the inability of the eye to adapt to changes in levels of light relative to the ambient background light that otherwise exists in the desired field of vision. Disability glare is in essence a “signal-to-noise” problem (where the “signal” is the light coming from the object to be viewed such as the car in front while driving and “noise” is light coming from all other objects in the background and periphery such as light reflected off of other cars, buildings, or coming directly from the sun during sunrise or sunset). It is similar to discerning speech in a location with loud background noise such as a crowded noisy restaurant or bar. The degree of disruption depends on many factors including intensity and size of the offending light source, the background luminance of the field of vision, the angular displacement of the offending light source relative to the axis of the line of sight, and continuous duration and/or the pulsed duration period of exposure. Glare exists when there is a significant difference between the light in the field of vision necessary to perform a task such as driving and the intensity of an offending light source in the same field of vision (Wördenweber, et al. 2007, Page 273).

Reflection of sunlight from a heliostat could be either specular or diffuse. However, about 95 percent of the light reflected from a mirrored heliostat is specular. The remaining incident light is either absorbed or diffusely reflected. The intensity of the diffusely reflected light will decrease as the inverse square of the distance from the heliostat. During normal operation the specular portion of the reflected light from the solar field will be directed at the central receiver Based on these factors staff believes that risk of significant visual impairment from glare would only be associated with strong specular reflection from the mirrored faces of heliostats in the solar field array.

There are three mechanisms of visual disruption caused by glint and glare that are typically associated with the task of driving. The first occurs when a large part of the visual field is at a very high luminance caused by a large offending light source, e.g., driving west into a sunset. This is referred to as saturation, veiling, or disability glare. The second mechanism causing visual disruption occurs when the desired field of vision on the road is disrupted by a sudden large increase in the luminance of the whole visual field e.g. such as when exiting a tunnel. This is referred to as adaption glare. The third mechanism is a very sudden extremely intense short duration flash of light causing complete bleaching of retinal photo pigments, e.g., the light flash from a camera flash. This type of light exposure is often referred to as flash blindness and is also associated with after images (Wördenweber, et al. 2007, Pages 273-4). All of these types of glare can persist for a significant period of time required for the eye to adjust to the post glare equilibrium condition.

When incident light is reflected from an optically flat smooth surface, the angle of incidence is equal to the angle of reflection. Under such conditions, the ultimate path of the reflected rays of light is determined by the geometry of the flat surface relative to the light source. The propensity for glint or glare to cause visual disability of a vehicle operator is strongly dependent on the angular deviation of the light source from the observer’s line of sight with small deviation from the line of sight significantly decreasing the sensitivity to visual impairment from offending light sources (See **Appendix TT2 – Tables 1** and **2**).

Appendix TT2 – Table 1

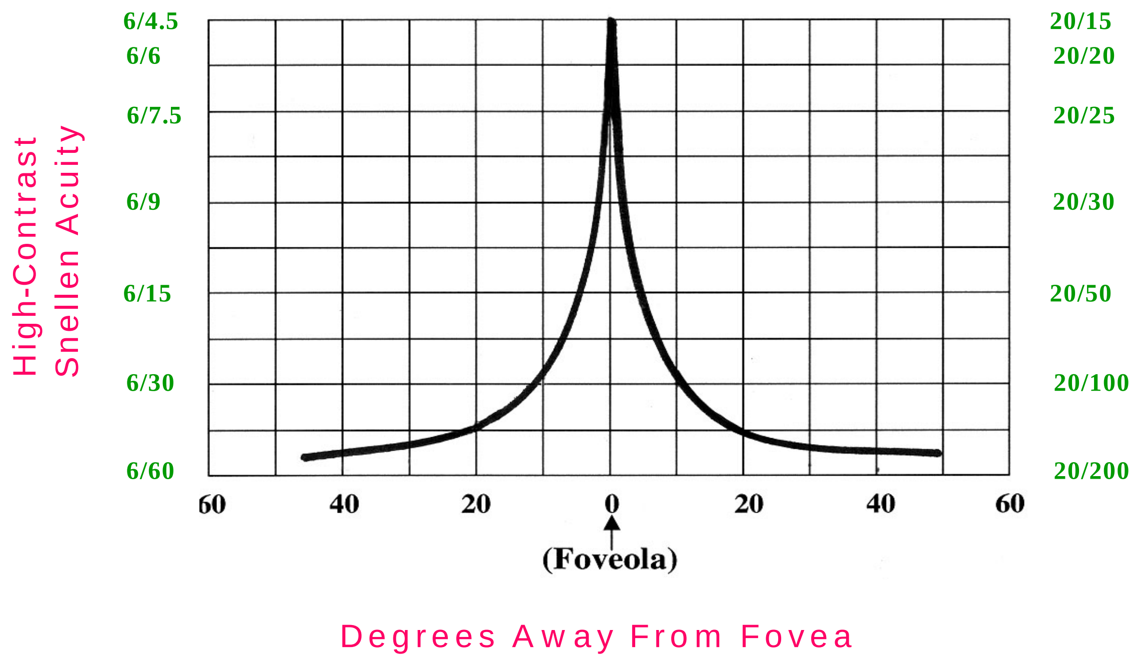
Source: Hans-Dieter Reidenbach

In fact, a light source that is displaced to the side of the field of vision can require 5 to 10 times the luminance of a light source directly in the line-of-sight to cause the same level of adaptive response (Bedell 1978, Page 5). This effect parallels retinal cone density, visual spatial resolution (acuity) and brightness perception as a function of displacement from the line-of-sight.

Thus, light sources that are directly in the line-of-sight are much more effective in creating disability glare. For example, the adverse effects of bright headlights are much greater on narrow two lane undivided roads than on wider multi-lane divided roads. Thus, the risk of creating disability glare is strongly dependent on the light source being located along the line of sight or at a small angle to it.

This effect of lower light sensitivity on the periphery of the visual field is also consistent with the physiology of the human eye. The cone photoreceptors in the retina are responsible for all visual function during daytime illumination conditions. The cones of the retina located at its center are responsible for fine visual acuity and are concentrated in the fovea region (the part of the eye located in the center of the macula region of the retina that is responsible for sharp central vision necessary for reading, driving, etc.). The density of cones drops very rapidly as a function of distance from the fovea, especially outside a ten degree visual radius. This structure accounts for the rapid decline in visual acuity and contrast that occurs as objects in the visual field deviate from the line of sight. Table 2 demonstrates this loss of acuity and light contrast as image moves from the center of the line of sight to the periphery of vision (FAA, undated).

Appendix TT2 – Table 2
Visual Acuity as a Function of Cone Distribution



Source: FAA – Laser Exposure

The hazard associated with driving in the presence of impairing glare is well documented and has resulted in a significant number of vehicular injuries and fatalities. The National Highway Traffic Safety Administration data estimate solar glare causes nearly 200 fatalities and thousands of motor vehicle accidents each year (NHTSA 2008). The phenomenon of visual impairment is the result of bright light in the field of vision that is more intense than the light reflected from objects illuminated by lower intensity ambient light, thus overwhelming the eyes' ability to compensate for the large contrast in light intensity. When such conditions occur they can impair a driver's visual acuity and ability to identify collision hazards. Common examples of such visual impairment is driving on a road traveling in a westerly direction at sunset when the direct light from the sun is shining in a driver's eyes or driving into bright headlights at night. In fact most accidents attributed to glare occur much more often at times close to sunrise and sunset.

Notwithstanding the eye's reduced sensitivity to glare sources which are displaced from its line of sight, any glint and glare sources of sufficient brightness and duration, are still capable of producing flash blindness if they occur within a driver's field of vision, even if substantially offset from his direct line of sight. The reflection from a mirrored surface such as a heliostat is a direct image of the sun and can thus produce light intensities similar to those associated with looking directly into the sun. If the reflected energy from a heliostat were to shine directly at oncoming traffic along the line of sight it could produce impairment similar to that caused by driving directly into the sun at sunset.

The proposed PSEGS project is located in very close proximity to I-10. The maximum speed limit on I-10 is 70 miles per hour. Thus, the available reaction time is very limited when a collision hazard is present. Therefore, any significant visual impairment associated with glint or glare from the proposed PSEGS project on I-10 would pose a serious risk to public safety.

Dose Response Assessment

Most assessments of risk associated with human exposure have focused on light intensity associated with permanent physical ocular damage. However, visual impairment can occur at exposures that are 2 to 4 orders of magnitude lower than those causing permanent injury to the eye (Ho, et. al, undated). As demonstrated in **Appendix TT2 – Table 3**, the threshold for ocular damage is several magnitudes greater than the threshold for flash blindness, a condition potentially hazardous to drivers. Based on studies by Saur and Dobrash, the lower limit of light intensity causing flash blindness lasting for less than a second is about 1 watt per square meter (W/m^2) at the eye (Ho, Ghanbari, and Diver (undated). In this assessment, staff could not quantitatively evaluate potential impacts and thus, did not rely on this metric for a risk determination. Staff's evaluation was instead based on the risk and plausibility of potential exposure that if it occurred could compromise the ability of a vehicle operator to avoid collision at high vehicle speeds.

Impairment of the driving task will occur only when offending glare is in the visual field of the driver. When the driver is looking forward, as is normal during the driving task, a direct heliostat exposure within, say, 10 degrees is highly improbable. To create a reflected beam from the closest heliostat that is offset perpendicular to I-10 by a distance of 220 feet from the west bound lane of the road, it would require a beam to travel a distance of more than 1,250 feet to align within 10 degrees) of a vehicle operator's line of sight. To align within 5 degrees of a driver's line of sight would require the reflected beam to cross the interstate at 2,500 feet. This is assuming that a heliostat is directed to precisely the optimum direction along the horizon. Such an alignment is would be very highly unlikely, even during a process control upset, once the heliostats are placed in operation and under automated control. If the alignment is even slightly above or below the horizon it would not be in the driver's field of vision at all at these distances.

However, if direct heliostat exposures should occur on I-10, line-of-sight exposures would be quite probable due to reflexive head and eye movements to regard (fixate) the glare source. There is a strong reflexive response to fixate a bright source suddenly introduced into the visual field. Most direct heliostat exposures, if in the drivers peripheral visual field and if sustained for more than 250-500 milliseconds, will be fixated and become optimally aligned with a driver's line of sight. At 70 miles per hour, a driver crossing through a five-meter wide heliostat beam, intercepting the interstate at 10 degrees would be exposed for 850 milliseconds and at 5 degrees for 1,700 milliseconds so that there could be sufficient exposure time for fixation to occur. Further, although the visual subtense (angular size of the object as viewed from some distance) of a heliostat is physically very small (much less than 1 degree), due to the potential maximum luminance (50-75 percent of one Sun's maximum luminance) there is very significant ocular (inside the eye) scatter and the resulting retinal stimulus (glare field) is much larger (Stine 2001). Observations at the ISEGS have resulted in 3-7 degree total visual field occlusions due to heliostat glare at viewing ranges of up to 5 miles. After such exposures and resuming the driving task, the central visual field of the driver will be transiently compromised for both visual acuity and contrast sensitivity.

Appendix TT2 – Table 3
Comparison of exposure levels causing permanent eye injury with those causing flash blindness

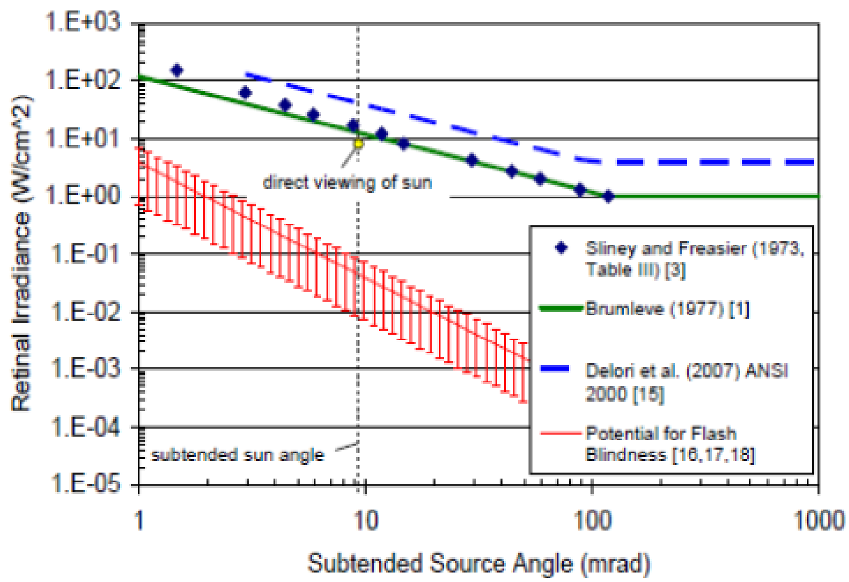


Figure 5. Retinal irradiance metrics as a function of subtended source angle for 0.15 s exposure (typical blink response time). Sliney and Freasier [3], Brumleve [1], and Delori et al. [15] provide safe retinal irradiance values to prevent irreversible eye damage. The range of retinal irradiances that can induce flash blindness is from several data sources [16], [17], [18].

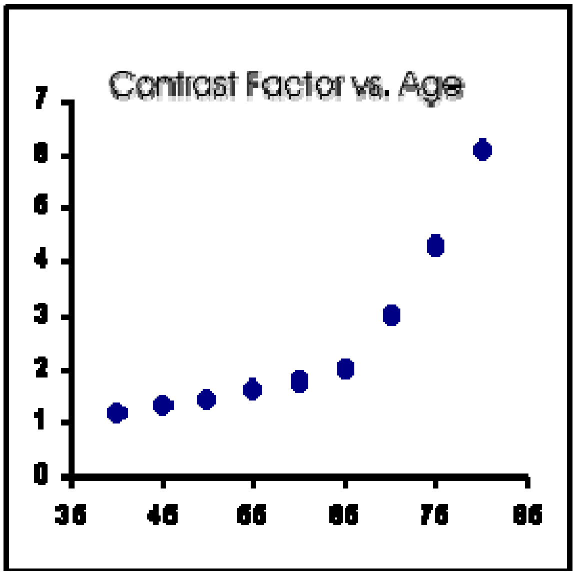
Source: Ho, et al., undated.

It should also be noted that there is considerable variability in the effectiveness of light adaptive response within the population of vehicle operators, including the factor of age (Green, 2009). As **Appendix TT2 – Table 4** below demonstrates, the adaptive capability decreases dramatically with age by about a factor of 10. Additionally, light eye color and use of corrective lenses can also in increase the potential disruptive effects on vision associated with glare. To establish a safe exposure criterion for flash blindness it would be necessary to use the 1.0 W/m^2 described above as a Lowest Observed Adverse Effect Level (LOAEL), applying a safety factor of 10, and resulting in a safe exposure criteria of 0.1 W/m^2.

Appendix TT2 – Table 4
Reduction of adaptive response to light contrast with age



Source: Marc Green, Ph.D. : Visual Forensics of Older Drivers

To establish exposure criteria from this data, it is necessary to divide the 1.0 W/m^2 threshold of adverse effect for flash blindness by a factor of at least 10 to account for response variability within the population of vehicle operators. This leads to a safe exposure criterion for irradiance from a heliostat on vehicle operators of $0.1 W/m^2$ to prevent potential for flash blindness in sensitive sub groups. However, staff questions the use of flash blindness as the most sensitive type of potential impairment. It is not clear that saturation glare such as occurs when driving into the sunset could not occur at lower intensities of light exposure than those associated with flash blindness.

To evaluate potential for saturation or veiling glare due to a malfunction or misorientation of a heliostat producing direct reflection of light onto traffic on I-10, staff utilized the Daylight Glare Index (DGI; Fan 2009, Suk 2012, Bembook 2013). Staff believes this scenario would represent a worst case exposure and that the DGI is the most appropriate glare index for evaluation of glare potential during bright daytime conditions. To conduct this analysis, staff evaluated a scenario where one of the heliostats closest to I-10 is assumed to be directed so that the reflected beam crosses the interstate and it is also assumed that the resultant reflection from the heliostat is along the horizon, such that the beam is at a driver's eyelevel when it crosses the road. This scenario also assumes that the sun is in a precise location where it could produce a reflected beam along the horizon and at an angle that crosses the interstate. It should be noted that this scenario is extremely unlikely or even implausible during normal operation of the facility and very unlikely otherwise (i.e. during construction or mal-operation). Therefore, this analysis represents an abnormal condition for illustrative purposes only. The DGI can be calculated using the following equations:

eq. 1

In this case, it is assumed that only one glare source exists and thus in the summation above n=1. Therefore the equation reduces to the following:

$$DGI = 10\ log_{10}\left(\frac{0.478\ L_S^{1.6}\ \Omega_S^{0.8}}{L_b + 0.07\omega_S^{0.5} L_S}\right) \qquad \text{eq. 2}$$

$$\Omega = \frac{\omega_S}{P_S^2} \qquad \text{eq. 3}$$

$$\ln(\mathrm{P}) = \left(35.2 - 0.3189\tau - 1.22e^{-\frac{2\tau}{9}}\right) \times 10^{-3}\sigma + (21 + 0.2667\tau - 0.002963\tau^2) \times 10^{-5}\sigma^2 \qquad \text{eq.4}$$

where τ and σ are incidence angles,

$$\omega_S = \frac{A_{heliostat}}{R^2} \qquad \text{eq.5}$$

where L_s = the luminance of the glare source (the luminance from the heliostat),

L_b = the luminance of the background (on a bright sunny day with high solar insolation),

ω_S = the subtended area of the glare source, and

P = the position index of the glare source with σ equal to 10 degrees and τ equal to 90 degrees.

Staff used a value of 0.8 x 10^9 candela per m^2 (cd/m^2) for L_s, a value of 10,000 cd/m^2 for L_b, a value of 1.09 for P calculated from equation 4 above, and a value of 21 x 10^{-6} for ω from equation 5. With these values the resultant DGI is 50. A value of 50 for the DGI would be well above an acceptable level and could even be termed “intolerable” (i.e.: DGI > 28) (Suk 2012) and therefore indicates a level of glare that would cause temporary flash blindness or other impairing glare in an exposed driver. Within a broad range of relevant angles and distances the DGI remains above 40, still in the “intolerable” range. Thus, if a heliostat or mirror were to malfunction and end up facing the interstate and all other conditions postulated above were to occur, the reflection from the heliostat would cause sufficient glare to impair the visual driving task on I-10. Practically, any heliostat in the solar field capable of directing an unobstructed reflection of the sun towards I-10, such that it falls within a driver’s field of vision, regardless of its distance and angular orientation with respect to I-10, has the potential to cause an impairment of the visual driving task.

Exposure Assessment

As mentioned above, the specular reflection of light (also called glint) is produced as a direct reflection of the sun onto a surface that is smooth at the microscopic level such as the mirrored surface of a heliostat. Visual impairment on I-10 is contingent on glint intercepting the path of oncoming traffic at the driver’s eye height. This could occur if the reflecting surface of a heliostat were to become oriented toward I-10 with the reflected beam nearly parallel to the horizon, for example with the sun being low on the horizon such that it would be reflected toward oncoming traffic. Even without safety measures incorporated into the automated heliostat controls to avoid unintended reflection (discussed below), virtually all operational conditions would dictate that the reflected light be directed upward toward the sky and toward the center of the solar field, or down toward the ground.

The normal operation of the proposed facility would result in reflected sunlight from the heliostats being directed toward the solar receiver on the top of the 750 foot high central tower in each solar field i.e. directed in a significantly upward direction well above the horizon (BrightSource, 2011). Each heliostat is under automatic computer control that optimizes this effect. Heliostats that are not directed at the tower are either automatically directed to the standby position just off the central receiver or to a default position with the reflecting surface facing directly up (BrightSource, 2011). If the automatic controls were to fail and the default positioning did not occur, the reflective surface would remain in the failed position as the harmonic drive gear and the linear drive gear chosen by the project owner to position heliostats' azimuth and elevation (respectively) would be required to lock in position when the gears stop rotation. This position would always be at an angle significantly above the horizon. Additionally, if the sun were on either horizon, its rays would be directed onto the back sides of the heliostat mirrors at the nearest edge of the solar field, and would be blocked from reaching the heliostats oriented with their reflective surfaces facing its rays, located on the opposite side of the solar field, even if local landscape topography did not already prevent it.

Therefore, the geometry of the heliostat field makes it implausible that the reflective surface of many of the heliostats would reflect along the horizon once the heliostats are properly installed. Only the heliostats on the very edge of the solar fields closest to the Interstate would be capable of reflecting any significant light onto I-10 without being blocked by other heliostats and then only if the heliostat were rotated by some unknown force such as the wind after failure of the supporting structures or harmonic or linear actuator drives of the control motors. Even if such a catastrophic failure were to occur, it is implausible that the failed heliostat would remain intact without being shattered or that it would come to rest in the very specific alignment along the line of sight required to potentially affect drivers.

However, the conditions described above are for operations and would not necessarily be present during construction. Thus, individual mirrors could reflect along the horizon and at a small angle nearly parallel to I-10 during and immediately after placement on the support structure. Additionally, individual mirrors could reflect onto I-10 during the construction, testing and calibration phases prior to power generation operations. This period can last many months and occurs prior to the rigorous implementation of the heliostat control algorithms (computer programs that control the movement of the heliostats) to avoid ground based direct exposures.

However, this risk can be easily mitigated by requiring the covering of the mirrored face of the individual heliostats until they are properly installed and oriented to the default position facing directly up or within the range of normal positioning, and subject to a method that implements directional exclusion zones (either through mechanical motion limiters or computer algorithms), to insure no direct exposure events at ground level occur on I-10 prior to operations.

Uncertainty Analysis

While staff was able to identify a safe exposure criterion for glare strong enough to potentially cause flash blindness, staff was unable to find a safe exposure level for more diffuse glare causing visual saturation. Yet, although staff is convinced that the potential for impairment from diffuse glare causing visual saturation would occur at lower exposure intensities than for flash blindness, the lack of a Lowest Observable Adverse Effect level (LOAEL) for visual saturation presents a significant uncertainly in any calculation of risk. However, staff believes that this uncertainty is inconsequential when compared to the numerous other uncertainties involved in an attempt to quantify the multiplicity of events that would have to occur to result in impairment of a driver on I-10. In other words, even if a safe exposure level were to exist for visual saturation glare, the other many uncertainties and remote possibilities would render any quantitative risk assessment unreliable and of little utility. Based on professional opinion and experience, staff finds that the probability of a heliostat becoming disoriented and then causing offending glare resulting in impairment of drivers' vision on I-10 is extremely low, making it a less-than-significant potential event.

Risk Characterization

Based on this analysis, staff concludes that the risk of glint or glare causing impairment of vehicle operators on I-10 is less than significant. Risk is the product of both the probability of occurrence and consequence of the undesirable effect. The consequences of visual impairment of a vehicle operator on I-10 would be high and potentially result in serious injuries and or fatalities. However, the probability of this event is so low as to be termed unlikely. The potential adverse outcome evaluated would require the concurrent occurrence of several independent events each having a very low probability.

Conclusions and Recommendations

Based on staff's qualitative analysis, it is implausible that glint and glare under normal operating conditions could cause vehicular accidents on I-10 in the vicinity of the proposed PSEGS facility. However, if a heliostat were to malfunction and end up facing the interstate such that drivers would experience a direct reflection within their field of vision, a significant visual impairment (flash blindness or impairing glare) could occur and result in a vehicular accident.

Under normal operating conditions, a numerical estimation of risk due to glint and glare would be extremely difficult to prepare – if not impossible due to the lack of certain objective criteria – and would not provide any further useful information about the risk or change staff's finding or recommendations.

Staff therefore recommends that the project owner be required to cover the mirrored surfaces of the heliostats during construction until they are properly seated, oriented, and under computer control and/or placed under the control of a directional exclusion zone program.

TRANSMISSION LINE SAFETY AND NUISANCE

Testimony of Obed Odoemelam, Ph.D.

SUMMARY OF CONCLUSIONS

The project owner, Palen Solar Holdings, LLC (PSH) proposes to transmit the power from the proposed Palen Solar Electric Generating System (PSEGS) to the Southern California Edison (SCE) transmission grid through SCE's Red Bluff Substation currently under construction near the community of Desert Center. The project's tie-in line would be a single-circuit 230-kV overhead transmission line connecting the project's on-site 230-kV switchyard to the SCE 220-kV Red Bluff Substation. When completed, this substation would be under the jurisdiction of the California Public Utilities Commission (PUC) and the Bureau of Land Management (BLM). Therefore, this staff analysis is for the tie-in project line as it stretches from the proposed on-site switchyard to the SCE substation. Since the proposed tie-in line would be located in the SCE service area, it would be constructed, operated, and maintained according to SCE's guidelines for line safety and field management which conform to applicable laws, ordinances, regulations and standards (LORS). The route for the proposed project line is undisturbed desert land with no nearby residents, eliminating the potential for residential electric and magnetic field exposures when the line is operating.

With the four proposed Conditions of Certification, any safety and nuisance impacts from routing the proposed tie-in line from the project site to the area around the community of Desert Center would be less than significant. These Conditions of Certification are unchanged from those required for the approved project, Palen Solar Power Project (PSPP).

INTRODUCTION

The purpose of this staff assessment is to assess the proposed PSEGS's transmission line's design and operational plan to determine whether its related field and nonfield impacts would constitute a significant environmental hazard in the areas around the proposed route as it runs between the proposed site and the community of Desert Center approximately 10 miles to the west. PSEGS would consist of two generating units whose generated power would be transmitted to SCE's Red Bluff Substation using an overhead single-circuit 230-kilovolt (kV) line. The substation is currently being built by SCE near the community of Desert Center. Since it is being built on federal land and within SCE's service area, the substation would be under the jurisdiction of the California Public Utilities Commission (PUC) and the Bureau of Land Management (BLM). This staff analysis is for the proposed PSEGS tie-in line and related on-site switchyard to be built and operated by the project owner. The potential impacts of concern are those to be encountered along the proposed corridor running between the project site and the SCE substation. All related health and safety laws, ordinances, regulations, and standards (LORS) are currently aimed at minimizing such impacts. Staff's analysis focuses on the following issues taking into account both the physical presence of the line and the physical interactions of its electric and magnetic fields:

- aviation safety;
- interference with radio-frequency communication;
- audible noise;
- fire hazards;
- hazardous shocks;
- nuisance shocks; and,
- electric and magnetic field (EMF) exposure.

Transmission Line Safety and Nuisance Table 1 below shows the federal, state, and local laws and policies that apply to the control of the field and nonfield impacts of electric power lines. Staff's analysis examines the project's compliance with these requirements.

METHODOLOGY AND THRESHOLDS FOR DETERMINING ENVIRONMENTAL CONSEQUENCES

The LORS and practices listed in TLSN Table 1 have been established to maintain impacts below levels of potential significance. Thus, if staff determines that the project would comply with applicable LORS, we would conclude that any transmission line-related safety and nuisance impacts would be less than significant. The nature of these individual impacts is discussed below together with the potential for compliance with the LORS that apply.

LAWS, ORDINANCES, REGULATIONS, AND STANDARDS (LORS)

Transmission Line Safety and Nuisance (TLSN) Table 1
Laws, Ordinances, Regulations, and Standards (LORS)

Applicable LORS	Description
Aviation Safety	
Federal	
Title 14, Part 77 of the Code of Federal Regulations (CFR),"Objects Affecting the Navigable Air Space"	Describes the criteria used to determine the need for a Federal Aviation Administration (FAA) "Notice of Proposed Construction or Alteration" in cases of potential obstruction hazards.
FAA Advisory Circular No. 70/7460-1G, "Proposed Construction and/or Alteration of Objects that May Affect the Navigation Space"	Addresses the need to file the "Notice of Proposed Construction or Alteration" form (Form 7640) with the FAA in cases of potential for an obstruction hazard.
FAA Advisory Circular 70/460-1G, "Obstruction Marking and Lighting"	Describes the FAA standards for marking and lighting objects that may pose a navigation hazard as established using the criteria in Title 14, Part 77 of the CFR.

Applicable LORS	Description
Interference with Radio Frequency Communication	
Federal	
Title 47, CFR, section 15.2524, Federal Communications Commission (FCC)	Prohibits operation of devices that can interfere with radio-frequency communication.
State	
California Public Utilities Commission (CPUC) General Order 52 (GO-52)	Governs the construction and operation of power and communications lines to prevent or mitigate interference.
Audible Noise	
Local	
Riverside County General Plan, Noise Element	Establishes policies and programs to ensure that noise levels are appropriate to land uses.
Riverside County Noise Ordinance	Establishes performance standards for planned residential or other noise-sensitive land uses.
Hazardous and Nuisance Shocks	
State	
CPUC GO-95, "Rules for Overhead Electric Line Construction." CPUC GO-128. Rules for Construction of Underground Electric Supply and Communication Systems.	Governs clearance requirements to prevent hazardous shocks, grounding techniques to minimize nuisance shocks, and maintenance and inspection requirements. Establishes requirements and minimum standards for installing underground lines and communication circuits.
Title 8, California Code of Regulations (CCR) section 2700 et seq. "High Voltage Safety Orders"	Specifies requirements and minimum standards for safely installing, operating, working around, and maintaining electrical installations and equipment.
National Electrical Safety Code	Specifies grounding procedures to limit nuisance shocks. Also specifies minimum conductor ground clearances.
Industry Standards	
Institute of Electrical and Electronics Engineers (IEEE) 1119, "IEEE Guide for Fence Safety Clearances in Electric-Supply Stations"	Specifies the guidelines for grounding-related practices within the right-of-way and substations.
Electric and Magnetic Fields	
State	
GO-131-D, CPUC "Rules for Planning and Construction of Electric Generation Line and Substation Facilities in California"	Specifies application and noticing requirements for new line construction including EMF reduction.
CPUC Decision 93-11-013	Specifies CPUC requirements for reducing power frequency electric and magnetic fields.
Industry Standards	
American National Standards Institute (ANSI/IEEE) 644-1944 Standard Procedures for Measurement of Power Frequency Electric and Magnetic Fields from AC Power Lines	Specifies standard procedures for measuring electric and magnetic fields from an operating electric line.

Applicable LORS	Description
Fire Hazards	
State	
14 CCR sections 1250-1258, “Fire Prevention Standards for Electric Utilities”	Provides specific exemptions from electric pole and tower firebreak and conductor clearance standards and specifies when and where standards apply.

PROPOSED MODIFIED PROJECT

The proposed PSEGS 230-kV tie-in line would consist of the following individual segments:

- A new, single-circuit 230-kV overhead transmission line extending the 10 miles from the on-site project switchyard to the SCE Red Bluff Substation under construction; and
- The project’s on-site 230-kV switchyard from which the conductors would extend to the Red Bluff Substation.

The overhead conductors would be aluminum steel-reinforced cables supported on steel pole structures placed approximately 1,100 feet apart and with a maximum height of 120 feet as typical of similar SCE lines. The width of the right-of-way would be approximately 120 feet (Solar Millennium 2009a, p. 2-27). The PSPP project applicant (Solar Millennium 2009a, p. 5.14-11) provided the details of the proposed support structures as related to line safety, maintainability, and field reduction efficiency. About 38 of these poles would be required in addition to poles for supporting turning points (PSH, 2013)

Building the PSEGS would involve a slight re-routing of the generation tie-line near the western end of the route around the new Red Bluff Substation (PSH, 2013). Such realignment would not significantly affect the levels of the field and nonfield impacts from the proposed modified project as compared to the previously approved project. Another modification-related change would be the elimination of the proposal to relocate the 161-kV SCE line in the immediate project area. This would not significantly affect the levels of the assessed line impacts.

SETTING AND EXISTING CONDITIONS

The two units of the proposed PSEGS (Unit 1 and Unit 2) would occupy a total of 3,794 acres of federal land currently managed by the BLM. The site is presently vacant, undeveloped desert approximately 0.5 miles north of Interstate 10 and 10 miles east of the rural community of Desert Center in eastern Riverside County. The power generated by each of the proposed units would flow from the high-voltage side of each unit’s transformer to a common switchyard located on the northern side of the site via underground copper cables. From there, the generated power would be transmitted to the SCE power grid using a single-circuit overhead, 230-kV line.

As previously noted, the point of connection with the SCE grid would be SCE's Red Bluff Substation approximately 10 miles to the west and currently under construction with completion expected by the end of 2013. Since this SCE substation would be under the jurisdiction of the PUC, it would be designed, built, and operated according to SCE guidelines in keeping with existing LORS.

The proposed project site is uninhabited, open desert land with no existing structures other than SCE's 161-kV Eagle Mountain-Blythe transmission that traverses the southwestern portion. There are only two residences within 2 miles of the project site and the transmission line. The closest is approximately 1,000 feet from the site boundary (Solar Millennium 2009, pp. 5.7-12 and 5.8-7). Since both buildings are unoccupied, there would not be the type of residential field exposures that have been of health concern in recent years over power line operation.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

DIRECT IMPACTS AND MITIGATION METHODS

Aviation Safety

For the PSEGS, any potential hazard to area aircraft would relate to the potential for collision in the navigable airspace. The requirements listed on **TLSN Table 1** establish the standards for assessing the potential for obstruction hazards within the navigable space and establish the criteria for determining when to notify the Federal Aviation Administration (FAA) about such hazards. These regulations require FAA notification in cases of structures over 200 feet from the ground. Notification is also required if the structure is to be below 200 feet in height but would be located within the restricted airspace in the approaches to public or military airports. For airports with runways longer than 3,200 feet, the restricted space is defined by the FAA as an area extending 20,000 feet from the runway. For airports with runways of 3,200 feet or less, the restricted airspace would be an area that extends 10,000 feet from this runway. For heliports, the restricted space is an area that extends 5,000 feet.

The closest operational airport of concern for the modified project is Blythe Airport, approximately 30 miles east of the project site and therefore too far away for the proposed line to pose an aviation hazard to utilizing aircraft. Also, the maximum height of 120 feet for the proposed line support structures (Solar Millennium 2009a, p. 2-27, and Figure 5.14-1) would be much less than the 200 feet that triggers the concern over aviation hazards according to FAA requirements.

Since (a) the physical dimensions of the proposed modified project's line structures are less than normally associated with collision hazards and (b) the distances from area aviation centers would be less that related to same collision hazard, staff does not find it necessary to recommend any aviation-related Conditions of Certification.

Interference with Radio-Frequency Communication

Transmission line-related radio-frequency interference is one of the indirect effects of line operation and is produced by the physical interactions of line electric fields. Such interference is due to the radio noise produced by the action of the electric fields on the surface of the energized conductor. The process involved is known as *corona discharge*, but is referred to as *spark gap electric discharge* when it occurs within gaps between the conductor and insulators or metal fittings. When generated, such noise manifests itself as perceivable interference with radio or television signal reception or interference with other forms of radio communication. Since the level of interference depends on factors such as line voltage, distance from the line to the receiving device, orientation of the antenna, signal level, line configuration and weather conditions, maximum interference levels are not specified as design criteria for modern transmission lines. The level of any such interference usually depends on the magnitude of the electric fields involved and the distance from the line. The potential for such impacts is therefore minimized by reducing the line electric fields and locating the line away from inhabited areas.

The PSEGS's transmission line would be built and maintained in keeping with standard SCE practices that minimize surface irregularities and discontinuities. Moreover, the potential for such corona-related interference is usually of concern for lines of 345 kV and above, and not for 230-kV lines such as the proposed line. The line's proposed low-corona designs are used for all SCE lines of a similar voltage rating to reduce surface-field strengths and the related potential for corona effects. Since the proposed line would traverse an uninhabited open space, staff does not expect any corona-related radio-frequency interference or related complaints and does not recommend any related Condition of Certification.

Audible Noise

The noise-reducing designs related to electric field intensity are not specifically mandated by federal or state regulations in terms of specific noise limits. As with radio noise, such noise is limited instead through design, construction, or maintenance practices established from industry research and experience as effective without significant impacts on line safety, efficiency, maintainability, and reliability. Audible noise usually results from the action of the electric field at the surface of the line conductor and could be perceived as a characteristic crackling, frying, or hissing sound or hum, especially in wet weather. Since the noise level depends on the strength of the line electric field, the potential for perception can be assessed from estimates of the field strengths expected during operation. Such noise is usually generated during rainfall, but mainly from overhead lines of 345 kV or higher. It is, therefore, not generally expected at significant levels from lines of less than 345 kV as proposed for PSEGS. Research by the Electric Power Research Institute (EPRI 1982) has validated this by showing the fair-weather audible noise from modern transmission lines to be generally indistinguishable from background noise at the edge of a right-of-way of 100 feet or more. Since the low-corona designs for the proposed modified project are also aimed at minimizing field strengths, staff does not expect the proposed line operation to add significantly to current background noise levels in the project area. For an assessment of the noise from the proposed line and related facilities, please refer to staff's analysis in the **NOISE AND VIBRATION** section.

Fire Hazards

The fire hazards addressed through the related LORS in **TLSN Table 1** are those that could be caused by sparks from conductors of overhead lines, or that could result from direct contact between the line and nearby trees and other combustible objects.

Standard fire prevention and suppression measures for similar SCE lines would be implemented by the project owner for the proposed modified project line (Solar Millennium 2009a, p. 5.14-10). Such measures are required under section 4292 of the Public Resources Code and section 1250 of Title 14 of the California Code of Regulations. The project owner's intention to comply with the clearance-related aspects of GO-95 would be an important part of this mitigation approach. Existing Condition of Certification **TLSN-3** is recommended to ensure compliance with all aspects of their intended fire prevention program.

Hazardous Shocks

Hazardous shocks are those that could result from direct or indirect contact between an individual and the energized line, whether overhead or underground. Such shocks are capable of serious physiological harm or death and remain a driving force in the design and operation of transmission and other high-voltage lines.

No design-specific federal regulations have been established to prevent hazardous shocks from overhead power lines. Safety is assured within the industry from compliance with the requirements specifying the minimum national safe operating clearances applicable in areas where the line might be accessible to the public.

Implementation of the GO-95- and GO-128-related measures against direct contact with the energized line would serve to minimize the risk of hazardous shocks for the proposed modified project. Existing Condition of Certification **TLSN-1** would be adequate to ensure implementation of the necessary mitigation measures.

Nuisance Shocks

Nuisance shocks are caused by current flow at levels generally incapable of causing significant physiological harm. They result mostly from direct contact with metal objects electrically charged by fields from the energized line. Such electric charges are induced in different ways by the line's electric and magnetic fields.

There are no design-specific federal or state regulations to limit nuisance shocks in the transmission line environment. For modern overhead high-voltage lines, such shocks are effectively minimized through grounding procedures specified in the National Electrical Safety Code (NESC) and the joint guidelines of the American National Standards Institute (ANSI) and the Institute of Electrical and Electronics Engineers (IEEE). For the proposed modified project line, the project owner will be responsible in all cases for ensuring compliance with these grounding-related practices within the right-of-way.

The potential for nuisance shocks around the proposed line would be minimized through standard industry grounding practices. Existing Condition of Certification **TLSN-4** will ensure compliance with standard industry grounding practices.

Electric and Magnetic Field Exposure

The possibility of deleterious health effects from EMF exposure has increased public concern in recent years about living near high-voltage lines. Both electric and magnetic fields occur together whenever electricity flows, and exposure to them together is generally referred to as EMF exposure. The available evidence as evaluated by the CPUC, other regulatory agencies, and staff has not established that such fields pose a significant health hazard to exposed humans. There are no health-based federal regulations or industry codes specifying environmental limits on the strengths of fields from power lines. Most regulatory agencies believe, as staff does, that health-based limits are inappropriate at this time. They also believe that the present knowledge of the issue does not justify any retrofit of existing lines.

Staff considers it important, as does the CPUC, to note that while such a hazard has not been established from the available evidence, the same evidence does not serve as proof of a definite lack of a hazard. Staff therefore considers it appropriate, in light of present uncertainty, to recommend feasible reduction of such fields without affecting safety, efficiency, reliability, and maintainability.

While there is considerable uncertainty about EMF health effects, the following facts have been established from the available information and have been used to establish existing policies:

- Any exposure-related health risk to the exposed individual will likely be small.
- The most biologically significant types of exposures have not been established.
- Most health concerns are about the magnetic field.
- There are measures that can be employed for field reduction, but they can affect line safety, reliability, efficiency, and maintainability, depending on the type and extent of such measures.

State's Approach to Regulating Field Exposures

In California, the CPUC (which regulates the installation and operation of many high-voltage lines owned and operated by investor-owned utilities) has determined that only no-cost or low-cost measures are presently justified in any effort to reduce power line fields beyond levels existing before the present health concern arose. The CPUC has further determined that such reduction should be made only in connection with new or modified lines. It requires each utility within its jurisdiction to establish EMF-reducing measures and incorporate such measures into the designs for all new or upgraded power lines and related facilities within their respective service areas. The CPUC further established specific limits on the resources to be used in each case for field reduction. Such limitations were intended by the CPUC to apply to the cost of any redesign to reduce field strength or relocation to reduce exposure. Publicly owned utilities, which are not within the jurisdiction of the CPUC, voluntarily comply with these CPUC requirements. This CPUC policy resulted from assessments made to implement CPUC Decision 93-11-013.

In keeping with this CPUC policy, staff requires a showing that each proposed overhead line would be designed according to the EMF-reducing design guidelines applicable to the utility service area involved. These field-reducing measures can impact line operation if applied without appropriate regard for environmental and other local factors bearing on safety, reliability, efficiency, and maintainability. Therefore, it is up to each project owner to ensure that such measures are applied in ways that prevent significant impacts on line operation and safety. The extent of such applications would be reflected by ground-level field strengths as measured during operation. When estimated or measured for lines of similar voltage and current-carrying capacity, such field strength values can be used by staff and other regulatory agencies to assess the effectiveness of the applied reduction measures. These field strengths can be estimated for any given design using established procedures. Estimates are specified for a height of 1 meter above the ground, in units of kilovolts per meter (kV/m), for the electric field, and milligauss (mG) for the companion magnetic field. Their magnitude depends on line voltage (in the case of electric fields), the geometry of the support structures, degree of cancellation from nearby conductors, distance between conductors, and, in the case of magnetic fields, amount of current in the line.

Since the CPUC currently requires that most new lines in California be designed according to the EMF-reducing guidelines of the electric utility in the service area involved, their fields are required under this CPUC policy to be similar to fields from similar lines in that service area. Designing the proposed modified project line according to existing SCE field strength-reducing guidelines would constitute compliance with the CPUC requirements for line field management.

The CPUC has revisited the EMF management issue to assess the need for policy changes to reflect the available information on possible health impacts. The findings specified in Decision D.06-1-42 of January 2006, did not point to a need for significant changes to existing field management policies. Since there are no residences in the immediate vicinity of the proposed modified project’s realigned transmission line, there would, as previously noted, not be the long-term residential EMF exposures mostly responsible for the health concern of recent years. The only project-related EMF exposures of potential significance would be the short-term exposures of plant workers, regulatory inspectors, maintenance personnel, visitors, or other individuals in the vicinity of the line. These types of exposures are short term and well understood as not significantly related to the health concern.

Industry’s and Project Owner’s Approach to Reducing Field Exposures

The present focus is on the magnetic field because unlike electric fields, magnetic fields can penetrate the soil, buildings, and other materials to produce the types of human exposures at the root of the health concern of recent years. The industry seeks to reduce exposure, not by setting specific exposure limits, but through design guidelines that minimize exposure in each given case. As one focuses on the strong magnetic fields from the more visible high-voltage power lines, staff considers it important, for perspective, to note that an individual in a home could be exposed to much stronger fields while using some common household appliances than from high-voltage lines (National Institute of Environmental Health Services and the U.S. Department of

Energy, 1998). The difference between these types of field exposures is that the higher-level, appliance-related exposures are short term, while the exposures from power lines are lower level, but long term. Scientists have not established which of these types of exposures would be more biologically meaningful in the individual. Staff notes such exposure differences only to show that high-level magnetic field exposures regularly occur in areas other than around high-voltage power lines.

As with similar SCE lines, specific field strength-reducing measures would be incorporated into the proposed line's design to ensure the field strength minimization currently required by the CPUC in light of the concern over EMF exposure and health.

The field reduction measures to be applied include the following:

1. increasing the distance between the conductors and the ground to an optimal level;
2. reducing the spacing between the conductors to an optimal level;
3. minimizing the current in the line; and
4. arranging current flow to maximize the cancellation effects from interacting of conductor fields.

Since the intended route of the proposed modified project line would have no residences in the immediate vicinity of the right-of-way, the long-term residential field exposures at the root of the health concern of recent years would not be a significant concern. The field strengths of most significance in this regard would be as encountered at the edge of the line's right-of-way. These field intensities would depend on the effectiveness of the applied field-reducing measures. The PSPP project owner (Solar Millennium 2009a, p. 5.14-8 and Figures 5.14-2 and 5.14-3) calculated the maximum electric and magnetic field intensities expected along the proposed route of the project line. Staff has verified the accuracy of the modeling approach used in the project owner's calculations with regard to parameters bearing on field strength dissipation and exposure assessment. The maximum electric field strength was calculated as 0.053 kV/m at the edge of the 150-foot right-of-way and is thus similar to those of SCE lines of the same voltage rating. The maximum magnetic field intensity of approximately 32.5 milligauss (mG) at the edge of this right-of-way is similar to that of SCE lines of the same current-carrying capacity (as required under current CPUC regulations) but is much less than the 200 mG currently specified by the few states with regulatory limits. The requirements in existing Condition of Certification **TLSN-2** for field strength measurements are intended to validate the project owner's assumed reduction efficiency.

NON-OPERATION AND FACILITY CLOSURE IMPACTS AND MITIGATION

If the proposed PSEGS were to be closed and all related structures are removed as described in the **PROJECT DESCRIPTION** section, the minimal area aviation risk electric shocks potential and fire hazards from the physical presence of this tie-in line would be eliminated. Closure and removal would also eliminate the transmission line's field impacts assessed in this analysis in terms of nuisance shocks, radio-frequency impacts, audible noise, and electric and magnetic field exposure. Since the line would be designed and operated according to existing SCE guidelines, these impacts would be as expected for SCE lines of the same voltage and current-carrying capacity and therefore, at levels reflecting compliance with existing health and safety LORS.

PROJECT-RELATED FUTURE ACTIONS

As previously noted, SCE is presently building the Red Bluff Substation, a new 220/500-kV substation southeast of Desert Center, in eastern Riverside County. The location is immediately north of and adjacent to the DPV1 transmission line where it will occupy approximately 90 acres when completed (First Solar, 2009). The construction of this substation is expected to be completed by the end of 2013.

The substation components will include a number of 220 kV and 500 kV transmission lines, 220/ 500 kV transformer banks, associated switch racks and a microwave tower (First Solar 2009). Other typical substation components include dead-end structures to allow the transmission line to enter the substation, and outdoor night lighting to illuminate the switch rack. Large substations like Red Bluff also require a mechanical-electrical equipment room that would house all the controls, protective equipment, and a telecommunications room. The tallest component of a 220/500 kV substation would likely be the terminating transmission tower or turning pole, which would range between 150 and 180 feet tall. The tallest component in the switch rack would likely be the dead-end pole, which would be approximately 130 feet tall. Other equipment would include disconnect switches, protective relays, metering and Supervisory Control and Data Acquisition (SCADA) system equipment. There would also likely be an emergency power generator, a fire prevention system (including hydrants, water tank, and walls between transformer phases), two single-story relay/control shelters, a single-story storage building, an oil containment system and a radio antenna tower to enhance communications. A permanent access road will provide vehicular access to the substation (First Solar 2009).

CUMULATIVE IMPACTS

The impacts from a specific project may, even at insignificant levels, combine with similarly low-level impacts from other nearby projects to produce the total effects that could be characterized as cumulatively considerable. For the proposed and similar projects, being, "cumulatively considerable" means that the incremental effects of an individual project would be significant when viewed in connection with the effects from past, existing or future projects (California Code Regulation, Title 14, Section 15130). NEPA, for example thus states that cumulative effects can result from individually minor, but collectively significant actions taking place over a period of time” (40 CFR §1508.7).

When field intensities are measured or calculated for a specific location, they reflect the interactive, and therefore, cumulative effects of fields from all contributing conductors. Such interactions could be additive or subtractive depending on prevailing conditions.

The staff of the Energy Commission has identified the existing or future area sources of the field and nonfield impacts of concern in this analysis. The sources were identified in terms of source and distance from the proposed project line. Their respective intensities and contributions to cumulative impacts would diminish with distance from each source. These individual impacts would be reflected in the levels estimated for the proposed line at the points of maximum interest. Since the proposed project line would be designed, built, and operated according to applicable field-reducing SCE guidelines (as currently required by the CPUC for effective field management), any contribution to cumulative area fields should be at levels expected for SCE lines of similar voltage and current-carrying capacity. It is this similarity in intensity that constitutes compliance with current CPUC requirements for EMF management. The actual field strengths and contribution levels for the proposed line design would be assessed from the results of the field strength measurements specified in existing Condition of Certification **TLSN-2**.

COMPLIANCE WITH LORS

As previously noted, current CPUC policy on safe EMF management requires that any high-voltage line within a given area be designed to incorporate the field strength-reducing guidelines of the main area utility lines to be interconnected. The utility in this case is SCE. Since the proposed project 230-kV line and related switchyard would be designed according to the respective requirements of the LORS listed in **TLSN Table 1**, and operated and maintained according to current SCE guidelines on line safety and field strength management, staff considers the proposed design and operational plan to be in compliance with the health and safety requirements of concern in this analysis. The actual contribution to the area's field exposure levels would be assessed from results of the field strength measurements required in existing Condition of Certification **TLSN-2**.

NOTEWORTHY PUBLIC BENEFITS

Since the proposed PSEGS tie-in line would pose specific, although insignificant risks of the field and nonfield effects of concern in this analysis, its building and operation would not yield any public benefits regarding the effort to minimize any human risks from these impacts.

RESPONSE TO COMMENTS

Staff received no comments relating to **Transmission Line Safety and Nuisance**.

CONCLUSIONS

Since staff does not expect the proposed 230-kV project transmission line to pose an aviation hazard according to current FAA criteria. We therefore do not consider it necessary to recommend specific location changes on the basis of a potential hazard to area aviation.

The potential for nuisance shocks would be minimized through grounding and other field-reducing measures that would be implemented in keeping with current SCE guidelines (reflecting standard industry practices). These field-reducing measures would maintain the generated fields within levels not associated with radio-frequency interference or audible noise.

The potential for hazardous shocks would be minimized through compliance with the height and clearance requirements of CPUC's General Order 95 and the placement requirements of GO-128 for the on-site underground segment. Compliance with Title 14, California Code of Regulations, section 1250, would minimize fire hazards while the use of low-corona line design, together with appropriate corona-minimizing construction practices, would minimize the potential for overhead corona noise and its related interference with radio-frequency communication.

Since electric or magnetic field health effects have neither been established nor ruled out for the proposed PSEGS and similar transmission lines, the public health significance of any related field exposures cannot be characterized with certainty. The only conclusion to be reached with certainty is that the proposed line's design and operational plan would be adequate to ensure that the generated electric and magnetic fields are managed to an extent the CPUC considers appropriate in light of the available health effects and safety information. The long-term, mostly residential magnetic exposure of health concern in recent years would be insignificant for the proposed line given the general absence of residences in the immediate vicinity of the intended route. On-site worker or public exposure would be short term and at levels expected for SCE lines of similar design and current-carrying capacity. Such exposure is well understood and has not been established as posing a significant human health hazard.

Since the proposed modified project line would be operated to minimize the health, safety, and nuisance impacts of concern to staff and would be routed through an area with no residences in its immediate vicinity, staff considers the proposed design, maintenance, and construction plan as complying with the applicable LORS. With implementation of the four existing Conditions of Certification, any such impacts would be less than significant.

PROPOSED CONDITIONS OF CERTIFICATION

Staff does not propose any changes to the existing Conditions of Certification for the proposed PSEGS project. The existing conditions are presented below.

TLSN-1 The project owner shall construct the proposed project transmission line according to the requirements of: (a) California Public Utility Commission's GO-95, GO-52, GO-131-D, GO-128, Title 8, and Group 2; (b) the High Voltage Electrical Safety Orders, sections 2700 through 2974 of the California Code of Regulations; and (3) Southern California Edison's EMF reduction guidelines.

Verification: At least 30 days prior to start of construction of the transmission line or related structures and facilities, the project owner shall submit to the Compliance Project Manager (CPM) a letter signed by a California-registered electrical engineer affirming that the lines will be constructed according to the requirements stated in the condition.

TLSN-2 The project owner shall use a qualified individual to measure the strengths of the electric and magnetic fields from the line at the points of maximum intensity along the route for which the project owner provided specific estimates. The measurements shall be made before and after energization according to the American National Standard Institute/Institute of Electrical and Electronic Engineers (ANSI/IEEE) standard procedures. These measurements shall be completed no later than six months after the start of operations.

Verification: The project owner shall file copies of the pre-and post-energization measurements with the CPM within 60 days after completion of the measurements.

TLSN-3 The project owner shall as part of its intended fire prevention program ensure that the right-of-way of the transmission line is kept free of combustible material, as required under the provisions of section 4292 of the Public Resources Code and section 1250 of Title 14 of the California Code of Regulations.

Verification: During the first five years of plant operation, the project owner shall provide a summary of inspection results and any fire prevention activities carried out along the right-of-way and provide such summaries in the Annual Compliance Report on transmission line safety and nuisance-related requirements.

TLSN-4 The project owner shall ensure that all permanent metallic objects within the right-of-way of the project-related line are grounded according to industry standards regardless of ownership.

Verification: At least 30 days before the line is energized, the project owner shall transmit to the CPM a letter confirming compliance with this condition.

VISUAL RESOURCES

Testimony of William Kanemoto and Gregg Irvin Ph.D.

SUMMARY OF CONCLUSIONS

California Energy Commission staff (hereafter referred to as staff) has analyzed visual resource-related information pertaining to the proposed Palen Solar Electric Generating System (PSEGS) and concludes that the proposed amended project would result in a substantial adverse impact to existing scenic resource values as seen from several viewing areas and Key Observation Points in the project vicinity and Chuckwalla Valley area, including:

- Eastbound and westbound Interstate 10 (I-10), which is located immediately south of the project site and transmission line;
- State Route 177, to the west and northwest of the project site;
- Joshua Tree National Park to the west and northwest of the project site;
- Palen McCoy Wilderness to the northeast of the project site;
- Chuckwalla Mountains Wilderness to the south of the project site; and
- Corn Springs Road in the immediate vicinity of the project site.

Staff concludes that these visual impacts would be significant in terms of three of the four criteria of California Environmental Quality Act (CEQA) Appendix G, could not be mitigated to less than significant levels, and would thus result in significant and unavoidable impacts under CEQA. Staff also concludes that the project's contribution to significant cumulative visual effects would be cumulatively considerable when combined with the effects of other renewable and development projects along the I-10 corridor, within the Chuckwalla Valley, and within the California Desert Conservation Area as a whole.

In addition, staff concludes that the project would be inconsistent with several goals and policies of the Riverside County Integrated Plan.

If the Energy Commission approves the amended project, staff recommends that the conditions of certification from the Commission Decision for the originally certified Palen Solar Power Project (PSPP), as modified herein by staff, be adopted in order to minimize impacts to the greatest feasible extent.

INTRODUCTION

Visual resources are the natural and cultural features of the environment that can be viewed. This analysis focuses on whether the Palen Solar Electric Generating System (PSEGS) would cause significant adverse visual consequences and whether the project would be in compliance with applicable laws, ordinances, regulations, and standards (LORS). The California Environmental Quality Act (CEQA) requires the California Energy Commission to determine the potential for significant impacts to visual resources resulting from the proposed project. **VISUAL RESOURCES APPENDIX VR-1** describes the visual resources methodology employed for the CEQA analysis (Energy

Commission staff's methodology), and the "Method and Threshold for Determining Significance," subsection below, describes the thresholds for determining environmental consequences (as discussed above in the "Summary of Conclusions" subsection). In accordance with staff's procedure, conditions of certification are proposed as needed to reduce potentially significant impacts (under CEQA) to less than significant levels or to the extent possible, and to ensure LORS conformance, if feasible.

EXISTING PROJECT VISUAL SETTING

REGIONAL SETTING

The proposed project landscape is part of the Great Basin section of Fenneman's Basin and Range physiographic province, a vast desert area of the western U.S. extending from eastern Oregon to western Texas, characterized by periodic north-south trending, highly eroded mountain ranges that rise sharply from and are separated by broad, flat desert valleys (Fenneman, 1931). The project region marks the transition zone between the high elevation Mojave Desert to the north and the arid, lower elevation Sonoran Desert to the south and east. The project site is located adjacent and to the north of I-10 in Chuckwalla Valley, approximately 9 miles east of Desert Center in eastern Riverside County. The Chuckwalla Valley is a broad, flat desert plain that includes scattered dry lakes and rolling sand dunes and is bordered by a number of rugged mountain ranges including the Eagle Mountains to the west and north, the Coxcomb and Granite Mountains to the north, the Palen Mountains to the northeast and the Chuckwalla Mountains to the south.

There are a number of sensitive land uses and protected areas within the expansive viewshed of the site including: to the north – Palen Dry Lake and Sand Dunes Area, and Desert Lily Sanctuary Area of Critical Environmental Concern (ACEC); to the northwest, Joshua Tree National Park; to the northeast – Palen McCoy Wilderness; to the east – Palen Dry Lake ACEC and Ford Dry Lake OHV Area; to the south – Chuckwalla Mountains Wilderness; and to the west – Alligator Rock ACEC and Desert Center. This portion of Chuckwalla Valley offers panoramic views of a desert plain landscape that appears relatively visually intact except for the presence of I-10 to the immediate south and two transmission lines. I-10 is the main travel corridor between Southern California and Phoenix, Arizona.

Project Site and Vicinity

The project site is presently undeveloped and consists mainly of desert scrub (largely scattered Creosote Bush), lakebed, and dune landscapes and is predominantly intact on the broad, Chuckwalla Valley floor (elevation 150 feet). There are three desert washes, indicated primarily by associated vegetation (desert dry wash woodlands), traversing the site (AFC, Page 5.15-7). A wood-pole, H-frame 161 kV transmission line passes through the southwestern corner of the project site. Several BLM 4WD roads that provide recreational access to Palen Dry Lake, the Palen Sand Dunes Area, Palen Dry Lake ACEC, and the perimeter of the Palen McCoy Wilderness also cross the site. **Visual Resources Figure 1**, *Characteristic Landscape of the Project Site*, presents a view of the project site from the BLM recreational access road just off the Corn Springs Road/I-10 off-ramp. The view presented in Figure 1 reveals a primarily natural setting comprised of a mosaic of sparse, shrubby vegetation of darker greens and tans, low-growing grasses and light-colored soils, rocks and desert pavement openings. Views from the site are panoramic, encompassing the open Chuckwalla Valley and the various mountain ranges that define the valley. The rugged ridges, angular forms and bluish hue of the Palen Mountains to the immediate east of the project site provide a contrast of visual interest to the flat, light-colored horizontal landform of the Chuckwalla Valley floor and project site. The area surrounding the project site is very lightly populated. There are two residences within 3,500 feet of the PSEGS northern boundary, one of which reportedly is occupied only seasonally (AFC, Page 5.15-9).

Project Viewshed

The *viewshed* or area of potential visual effect (the area within which the project could potentially be seen) is extensive and encompasses much of Chuckwalla Valley and the site-facing slopes and ridgelines of the surrounding mountains as indicated by the yellow colored area in **Visual Resources Figure 2,** *Project Viewshed*. The computer-generated viewshed mapping is based on the height of the proposed towers. The mapping is accurate within the limits of error of the 10-meter resolution (horizontal) USGS digital elevation model (DEM). In this landscape, because of the general absence of tall land-cover that could alter the actual viewshed, the topographically generated viewshed mapping is considered generally accurate. A feature of this desert landscape is the potential for large projects to be seen over great distances where elevated viewpoints exist, due to the large open areas of level topography and absence of intervening landscape features.

ORIGINAL APPLICATION PROJECT DESCRIPTION

The original approved 2010 Palen Solar Power Project (PSPP) was proposed to occupy roughly the same site as the current PSEGS project, but on a somewhat different footprint. The PSPP proposed a 4.5 square-mile solar thermal generating facility utilizing solar trough technology, consisting of fields of long, linear rows of parabolic mirrors, as well as associated generation facilities. The maximum height of the mirror structures is approximately 25 feet. In addition, various structures such as steam generators, air-cooled condenser, and water-storage tanks would comprise the power generation block. The air-cooled condenser would be 150 feet tall. Other structures in the power block would vary in height but would be considerably shorter. The predominant visual profile of the solar trough power plant would thus be of a vast, level mirror field, relatively low in height (25 feet), with two taller; approximately 26-acre power blocks in the center of two mirror fields. Occasional bright ’glint ‘ reflections of the sun off the mirrors, perceptible to viewers on the ground under certain conditions and times of day, were noted as a potential concern in the review of the PSPP and other solar trough projects. These events are assumed occasional and transitory.

Overall, the visual analysis of the Revised Staff Assessment concluded that the PSPP would cause moderate-to-high levels of visual change for viewers in the Chuckwalla Valley at foreground and middle-ground distances, particularly from Highway I-10; and moderate-to-high levels of visual change for higher elevation viewers in the mountains of the Palen-McCoy and Chuckwalla Mountains wilderness areas, to background distances (over 5 miles distance).

Based on these findings the Energy Commission concluded that proposed conditions of certification would not reduce the project's visual impacts to a less-than-significant level. The Commission also concluded that the PSPP would contribute to significant cumulative visual impacts in the I-10 corridor. The Commission approved the PSPP with a Statement of Overriding Considerations.

AMENDED PROJECT VISUAL DESCRIPTION

As the prior approved project, the proposed amended project would convert a vast area of naturally appearing desert plain to an industrial facility characterized by complex, geometric forms and lines and industrial surfaces that are dissimilar to the surrounding natural landscape character. The overall area of the amended project would be 572 acres smaller than the approved PSPP. Much of the developed area would be covered with the arrays of heliostats (elevated mirrors) that would be used to collect heat energy from the sun. Like the PSPP, these mirror-fields would be relatively low in height (assumed to be under 20 feet maximum height). The amended project would however include two 750-foot-tall solar towers topped by 130-foot-tall solar receivers (SRSGs) that would concentrate the sunlight reflected by the field of heliostats to create steam, as well as reflect sunlight outward. For context, the towers would be the fifth tallest structures in California. The super-heated SRSGs would act as extremely bright sources of light. Similar to the PSPP, the amended project would also include various power-generation structures and a power transmission line from the project site extending westward to the Red Bluff substation, under construction south of I-10 between the project site and Desert Center. The greatest potential for public views of the transmission line would be from I-10 immediately to the south and State Highway 177 roughly 9 miles to the west. The project's transmission line route traverses Colorado Desert Creosote Bush Scrub community shrubs and grasses. **Attachments 1A through 1D** in the **VISUAL RESOURCES APPENDIX VR-1** present typical heliostat (1A), solar tower/power block elevation (1B), project layout (1C), and transmission line route (1D). **Visual Resources Table 1** provides a list of the major project features that would contribute to the apparent visual change of the landscape. A more detailed discussion of the proposed project is presented in the **PROJECT DESCRIPTION** section of this document. In addition to the features listed in Table 1 below, the proposed project would also include the installation of chain link fencing and desert tortoise fencing around the perimeter of the site for security and protection of sensitive biological resources.

Visual Resources Table 1
Key Project Components

Component	Dimensions (LxWxH) (Feet) / Capacity	Footprint (square feet)
Common Area		
Administration Building	180 x 80 x 34	14,400
Maintenance and Electrical Shops and Warehouse	90 x 120 x 48	10,800
Fire Water Storage Tank	25 (diameter) 15 (height)	NA
Fire Water Pump House	12 x 36 x 10	432
Emergency Diesel Generator Enclosure	12 x 18 x 10	216
Power Block #1		
Solar Tower including Solar Receiver Steam Generators	75 (diameter) 750 (height)	NA
Steam Turbine Generator Enclosure	34 x 46 x 52	1,564
Air Cooled Condenser	220 x 300 x 120	NA
Steam Turbine Enclosure	40 x 56 x 52	2,240
Steam Turbine Generator Lube Oil Enclosure	22 x 38 x 18	836
Deaerator/Feedwater Heater Structure	56 x 66 x 80	NA
Emergency Diesel Generator Enclosure	12 x 32 x 12	384
Plant Service Building	56 x 100 x 16	5,600
ACC Power Distribution Center – North	14 x 50 x 16	700
ACC Power Distribution Center – South	14 x 50 x 16	700
Fire Water Pump House	36 x 12 x 12	432
Demineralized Water Storage Tank	26 (diameter) 26 (height)	NA
Service/ Firewater Storage Tank	40 (diameter) 30 (height)	NA
Mirror Wash Water Storage Tank	25 (diameter) 21 (height)	NA
Boiler Pump Power Distribution Center	50 x 14 x 16	700
Waste Water Storage Tank	25 (diameter) 23 (height)	NA
Water Treatment Power Distribution Center	30 x 14 x 16	420
Night Preservation Auxiliary Boiler	10 x 12 x 12	NA
Start-up Auxiliary Boiler	14 x 56 x 16	NA
Mirror Wash Vehicle Refueling and Storage Area Canopy	74 x 116 x 24	NA
Mirror Wash Vehicle Storage Area Canopy	40 x 184 x 20	NA
Wet Surface Air Cooler (WSAC)	48 x 36 x 26	NA
Thermal Evaporation Unit	34 x 18 x 64	NA
Residue Tank	12 (diameter) 13 (height)	NA
Water Treatment Building	66 x 90 x 26	5,940
Generator Step-up Transformer	12 x 26 x 22	NA
Drains Tank	12 (diameter) 13 (height)	NA
Power Block #2		
Solar Tower including Solar Receiver Steam Generators	75 (diameter) 750 (height)	NA
Steam Turbine Generator Enclosure	34 x 46 x 52	1,564
Air Cooled Condenser	220 x 300 x 120	NA
Steam Turbine Enclosure	40 x 56 x 52	2,240
Steam Turbine Generator Lube Oil Enclosure	22 x 38 x 18	836
Deaerator/Feedwater Heater Structure	56 x 66 x 80	NA
Emergency Diesel Generator Enclosure	12 x 32 x 12	384
Plant Service Building	56 x 100 x 16	5,600
ACC Power Distribution Center – North	14 x 50 x 16	700
ACC Power Distribution Center – South	14 x 50 x 16	700

Component	Dimensions (LxWxH) (Feet) / Capacity	Footprint (square feet)
Fire Water Pump House	36 x 12 x 12	432
Demineralized Water Storage Tank	26 (diameter) 26 (height)	NA
Service/ Firewater Storage Tank	40 (diameter) 30 (height)	NA
Mirror Wash Water Storage Tank	25 (diameter) 21 (height)	NA
Boiler Pump Power Distribution Center	50 x 14 x 16	700
Waste Water Storage Tank	25 (diameter) 23 (height)	NA
Water Treatment Power Distribution Center	30 x 14 x 16	420
Night Preservation Auxiliary Boiler	10 x 12 x 12	NA
Start-up Auxiliary Boiler	14 x 56 x 16	NA
Mirror Wash Vehicle Refueling and Storage Area Canopy	74 x 116 x 24	NA
Mirror Wash Vehicle Storage Area Canopy	40 x 184 x 20	NA
Wet Surface Air Cooler (WSAC)	48 x 36 x 26	NA
Thermal Evaporation Unit	34 x 18 x 64	NA
Residue Tank	12 (diameter) 13 (height)	NA
Water Treatment Building	66 x 90 x 26	5,940
Generator Step-up Transformer	12 x 26 x 22	NA
Drains Tank	12 (diameter) 13 (height)	NA

LAWS, ORDINANCES, REGULATIONS, AND STANDARDS

Staff also evaluates the project to determine compliance with federal, state and local laws, ordinances, regulations and standards (LORS). **Visual Resources Table 3** lists relevant LORS pertaining to aesthetics or the preservation and protection of sensitive visual resources, and presents a discussion of project conformance with them. **Visual Resources Table 3** may be found at the end of the section, following the discussion of project impacts and mitigation under CEQA, under “Compliance with Applicable LORS.”

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

This section includes information about the following:

1. Method and threshold for determining significance

2. Direct/indirect/induced impacts and mitigation

3. Cumulative impacts and mitigation

METHOD AND THRESHOLD FOR DETERMINING SIGNIFICANCE

CEQA Criteria of Significance

The following regulatory criteria were considered in determining whether a visual impact would be significant under CEQA.

The CEQA *Guidelines* define a “significant effect” on the environment to mean a “substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project including...objects of historic or aesthetic significance.” (Cal. Code Regs., tit.14, §15382.) Appendix G of the *Guidelines*, under

Aesthetics, lists the following four questions to be addressed regarding whether the potential impacts of a project are significant:

1. Would the project have a substantial adverse effect on a scenic vista?

2. Would the project substantially damage scenic resources, including, but not limited to, trees, rock outcroppings, and historic buildings within a state scenic highway?

3. Would the project substantially degrade the existing visual character or quality of the site and its surroundings?

4. Would the project create a new source of substantial light or glare which would adversely affect day or nighttime views in the area?

Key Observation Points (KOPs)

The visual resources approach is based on detailed analysis from representative Key Observation Points (KOPs). KOPs are generally selected to be representative of the most critical locations from which the project would be seen. KOPs are selected based on their usefulness in evaluating existing landscapes and potential impacts on visual resources with various levels of sensitivity, in different landscape types and terrain, and from various vantage points. Typical KOP locations for the proposed project and alternatives include (1) along major or significant travel corridors (I-10); (2) along recreational access 4WD roads and trails; (3) at key vista points; (4) from publicly accessible vantage points within designated Wilderness or other protected areas; and (5) at locations that provide good examples of the existing landscape context and viewing conditions.

At each KOP, the existing landscape was characterized by photographs that were obtained to indicate existing conditions without the project and then were modified to include a simulation of the project. Consequently, staff has a visual representation of the viewshed before and after a project is introduced to assist in the analysis.

Energy Commission staff evaluated the visual setting and proposed project in detail from several viewing areas represented by existing and simulated views of the following six key observation points, provided by the project owner and shown in **Visual Resources Figure 3,** *Key Observation Points (KOPs).* The project owner's simulations were taken from two submittals with different KOP numbering systems (Solar Millennium 2009a; Palen 2013w). To minimize confusion, a new KOP numbering system is adopted for this report, as described below and depicted in Figure 3. For each KOP, the equivalent KOP number from the relevant document is also provided in parentheses. 'VRA' refers to KOP numbers assigned in the project owner's *PSEGS Visual Resource Analysis Report, May 2013* (Palen 2013w).

- **KOP 1** (VRA 3) – State Route 177, approximately 7 miles northwest of the project site, and approximately 8 miles northwest of the nearest solar tower, looking to the southeast. This KOP is representative of views from the SR 177 corridor. It also represents the nearest viewpoint within Joshua Tree National Park (JTNP, background distance).

- **KOP 2** (VRA 7) – Northwest of Desert Center, approximately 13 miles northwest of the project site, and approximately 14 miles northwest of the nearest solar tower, looking southeast. This viewpoint is the second nearest viewpoint to the project within JTNP (background distance).
- **KOP 3** (AFC 8B) – Eastbound Interstate 10 (I-10), approximately 0.5 mile west of the western boundary of the project site, and approximately 1.5 miles southwest of the nearest solar tower, looking to the east. This KOP represents the view of motorists traveling along I-10 (eastbound, middleground distance).
- **KOP 4** (VRA 13) – Westbound Interstate 10 (I-10), approximately 6.4 miles southeast of the southeast corner of the project site, and approximately 5.7 miles southeast of the nearest solar tower, looking to the northwest. This KOP represents the view of motorists traveling along I-10 (westbound, background distance).
- **KOP 5** (VRA 12) – Chuckwalla Mountains Wilderness, approximately 5 miles southwest of the project site, and approximately 6 miles southwest of the nearest solar tower, looking to the northeast. This KOP represents elevated views within the Chuckwalla Mountains Wilderness at background distance.
- **KOP 6** (VRA 15) – Palen McCoy Wilderness, approximately 3.5 miles northeast of the project site, and approximately 4.5 miles northeast of the nearest solar tower, looking to the southwest. This KOP represents elevated views within the Palen McCoy Wilderness at middle-ground-distance.

Each of these six key observation points is shown on **Visual Resources Figure 3**. At each KOP, a visual analysis was conducted and a discussion of the visual setting for each KOP is presented in the subsection entitled “C. Visual Character or Quality” below, and summarized in tabular form in **Visual Resources Table 2**. Existing conditions photographs and visual simulations of the project are presented in **VISUAL RESOURCES APPENDIX VR-2**.

DIRECT/INDIRECT IMPACTS AND MITIGATION

This analysis considered the potential impacts of the proposed project in relation to the four significance criteria for visual resource impacts listed in Appendix G of the CEQA Guidelines, under Aesthetics, specified above.

A. <u>Scenic Vistas</u>

”Would the project have a substantial adverse effect on a scenic vista?”

For the purposes of this analysis, a *scenic vista* is defined as a designated scenic vista (identified in public planning documents); a view of high scenic quality perceived through and along a corridor or opening; or a view from a designated scenic area. While not the sole criterion for designation of wilderness areas, preservation of scenic values is a key concern underlying the Wilderness Act (P.L. 88-577 (16 U.S. C. 1131-1136)). The highly scenic, currently unspoiled views from elevated viewpoints within the Palen McCoy and Chuckwalla Mountains Wilderness areas are thus considered here to represent scenic vistas.

Yes. Although no designated scenic vistas were identified in the study area, panoramic and highly scenic vistas are available to backcountry recreationists that access the southern ridges of the Palen McCoy Wilderness and the northeastern ridges of the Chuckwalla Mountains Wilderness. Both areas overlook the expansive Chuckwalla Valley ringed by distinguishable mountain ranges. The brightness of glare from the project's two solar receivers would be seen from the two wilderness areas (WAs) at distances of as little as 4.5 miles. At this distance, based on information provided by the project owner, staff has determined that the solar receiver steam generators (SRSGs) would appear to viewers as very bright and prominent. While not physically damaging to the eyes, this level of brightness could impair the recreational use of the WAs within the viewshed of the SRSGs, introducing a prominent, distracting, very bright industrial feature into the wilderness experience within an estimated range of up to 10 miles from the solar towers. Refer to **APPENDIX TT1 - VISUAL SAFETY IMPACT ASSESSMENT** in the **TRAFFIC AND TRANSPORTATION** section of the Final Staff Assessment (FSA) for a more detailed discussion. Thus, within some substantial portion of the exposed wilderness areas, the solar towers and SRSGs would exhibit a high level of contrast with the existing natural background landscape. They would exhibit strong visual dominance, demanding attention. Because wilderness viewers are assumed to have a high level of viewer concern and moderately high overall visual sensitivity, this strong contrast would represent a substantial adverse visual and glare effect.

As shown in **Visual Resources Figures 8B and 9B**, the project would be prominently visible from both wilderness areas and the introduction of glare; industrial character and structural visual contrast would result in substantial adverse effects on these vistas. These effects are discussed under KOPs 5 and 6, below. In addition, based on information provided by the project owner, the SRSGs could potentially have substantial adverse glare effects on certain viewpoints in the easternmost portions of the JTNP as depicted in **Visual Resources Figures 4B and 5B**. These effects are discussed under KOPs 1 and 2, below.

B. Scenic Resources

"Would the project substantially damage scenic resources, including, but not limited to, trees, rock outcroppings, and historic buildings within a state scenic highway?"

For the purpose of this analysis, *scenic resources* include a unique water feature (waterfall, transitional water, part of a stream or river, estuary); a unique physical geological terrain feature (rock masses, outcroppings, layers or spires); a tree having a unique/historical importance to a community (a tree linked to a famous event or person, an ancient, old growth tree); historic building; or other scenically important physical features, particularly if located within a designated federal scenic byway or state scenic corridor.

No. The Chuckwalla Valley floor consists primarily of desert scrub vegetation. The project site is located adjacent and to the north of I-10, which is not listed as an eligible State Scenic Highway, and there are no notable scenic features or historic structures located within the site. Therefore, the project would not substantially damage scenic resources such as trees, rock outcroppings, or historic buildings within a state scenic highway.

C. Visual Character or Quality

"Would the project substantially degrade the existing visual character or quality of the site and its surroundings?"

CEQA Criterion C is typically determined by staff's visual sensitivity/visual change assessment methodology, applied through analysis of representative KOPs throughout the project viewshed. However, due to the unusual character of the proposed project, visual impact conclusions under Criterion C revolve primarily around predicted effects of glare from the SRSGs, whose effects would be much stronger and extend much farther than those from visual change and contrast from the project structures themselves. The reader should thus also refer to the discussion of Criterion D, Light and Glare, and to the discussion in **APPENDIX TT1 – VISUAL SAFETY IMPACT ASSESSMENT** in the **TRAFFIC AND TRANSPORTATION** section of this FSA.

Yes. The proposed project would introduce prominent structures with industrial character into the foreground to background views from SR 177 and the Desert Center area (see KOPs 1 and 2), I-10, Corn Springs Road (see KOPs 3, 4 and 5), nearby wilderness areas (see KOPs 6 and 7), Joshua Tree National Park (see KOPs 1 and 2), and a few nearby residences. The resulting visual change would range from moderate to high among these KOPs and, overall, result in a substantial degradation of the existing visual character or quality of the site and its surroundings.

The visual aspects evaluated according to Criterion C are organized into two categories: 1) construction impacts and 2) operational impacts.

Construction Impacts and Mitigation

Construction of the proposed project would cause temporary visual impacts due to the presence of equipment, materials, and workforce. These impacts would occur at the proposed solar power plant site and along the transmission line route. Construction would involve the use of cranes, heavy construction equipment, temporary storage and office facilities, and temporary laydown/staging areas. Construction would include site clearing and grading, construction of the actual facilities, and site cleanup and restoration. Visible traffic would also increase along I-10 and the BLM recreational access road during construction and grading activities would generate large dust clouds, which can be visually distracting if not controlled properly. Construction activities would be visible from I-10 (the primary travel corridor in the region), nearby BLM recreational access roads, the few residences in the area, SR 177, Palen McCoy Wilderness, and Chuckwalla Mountains Wilderness. Throughout the extensive construction period of approximately 33 months, the industrial character of the activities would constitute adverse and significant visual impacts. However, the vast majority of the area disturbed by construction would eventually be occupied by project facilities (see the “Operational Impacts and Mitigation” subsection below) though some areas of disturbed soil surfaces (characterized by high color, line and texture contrasts) would remain and would be visible from the various viewing vantage points. These areas of residual disturbance would require successful restoration. Proper implementation of Condition of Certification **VIS-2** would ensure that the visual impacts of residual disturbed areas associated with project construction remain less than significant. It is also anticipated that construction activity will take place at night. Implementation of Condition of Certification **VIS-3**, presented later in this analysis, would ensure that significant construction lighting impacts do not occur.

Operational Impacts and Mitigation

An analysis of operation impacts was conducted for the view areas represented by the key viewpoints selected for in-depth visual analysis. The results of the operation impact analysis are discussed below by KOP and presented in **Visual Resources Table 2**. The visual impacts of night lighting are discussed in a separate section of this analysis. For each KOP, an evaluation of visual contrast, project dominance, and view blockage is presented with a concluding assessment of the overall degree of visual change caused by the proposed project. Visual change is then considered within the context of viewers’ overall visual sensitivity to arrive at a determination of visual impact significance.

The analysis that follows is based in part on visual simulations provided by the project owner and reproduced at the end of this section. It should be noted that judgments of visual contrast and dominance should be based on reproductions of the simulations at ‘life-sized’ scale (i.e., at a scale that reproduces the viewing conditions as seen by the naked eye at the site of the KOP). Based on camera lens information provided to staff, this implies figure reproduction at approximately ledger-size, viewed at normal reading distance. It is also noted that brightness of glare sources such as the SRSGs cannot be reproduced in a printed (or projected) image.

KOP 1 – State Route 177 Corridor/Coxcomb Mountain (JTNP)

KOP 1 was selected to characterize the visual impact to residents, park visitors, and motorists on and around State Route (SR) 177, in the area northwest of the proposed project. KOP 1 is located near southbound SR 177, approximately 7 miles northwest of the project site and 8.7 miles to the nearest solar tower (background distance). The view is to the southeast and is depicted in **Visual Resources Figure 4A**. The existing landscape within the SR 177 corridor varies in character, quality, and sensitivity. Much of the corridor between Desert Center and the KOP is typified by disturbance from human activity in the foreground. From the vicinity of the KOP northward, views are intact and natural in appearance. In addition, a range of high-sensitivity viewers is present in this portion of the viewshed, including national park visitors and residents.

Visual Quality: Moderately low. The foreground to middleground views from SR 177 encompass a broad, open and predominantly undeveloped landscape, punctuated however by various signs of human habitation in the highway foreground, including rural residences, jojoba and palm farming, and an auto wrecking yard. From the vicinity of the KOP northward, views are intact and undisturbed by human uses. The KOP is also within the easternmost portion of the JTNP, where the park boundary adjoins SR 177. The landscape in this portion of the viewshed consists of a relatively non-descript, flat, grass- and shrub-covered plain, back-dropped by the angular forms of the Palen and Chuckwalla Mountains to the east and southeast, and the Granite and Coxcomb Mountains to the north. The mountain ranges add visual interest and contribute to the low-to-moderate rating for visual quality.

Viewer Concern: High. Viewer concern is considered particularly high at this KOP due to its location within the JTNP. Similarly, the Desert Lily ACEC is located a short distance from the KOP. In addition, residential viewers in the general SR 177 corridor, including homes along SR 177 and the Lake Tamarisk neighborhood to its west, would have high viewer concern. Viewers at commercial operations, such as farms, an auto-wrecking yard and the Chuckwalla Valley Raceway would have moderately low or low viewer concern. Viewer concern of motorists in this segment of SR 177 is considered moderate. Motorists' expectations would be moderated by the existing intrusion of visual disturbances, although some proportion of motorists would be en route to or from JTNP. Overall, however, due to the high sensitivity of national park, ACEC, and residential viewers, viewer concern in the SR 177 corridor is considered high.

Viewer Exposure: Moderately high. Site visibility is high in that the view of the site from KOP 1 is largely unobstructed. Although the site is at background distance from the KOP, the very tall and extremely bright towers would exert strong visual influence over an unusually large range, extending well into background distances. Based on available information, the SRSGs would be highly prominent from the SR 177 corridor, due particularly to glare. The number of viewers within the SR 177 corridor is moderate. The view duration for residents is high. For motorists view duration would be extended, with uninterrupted sightlines to the site for many miles of travel distance. The high visibility, moderate number of viewers, and extended duration of view would result in moderately high viewer exposure.

Overall Visual Sensitivity: Moderately high. For viewers at KOP 1 and along SR 177, the low-to-moderate visual quality combined with high viewer concern and moderately high viewer exposure result in an overall moderate-to-high visual sensitivity of the visual setting and viewing characteristics.

Visual Resources Figure 4B presents a visual simulation of the proposed project and illustrates the visibility of the project area as viewed from KOP 1.

Visual Contrast: High. As indicated in the simulation, the solar towers and taller features of the power block would remain visible even at this distance, presenting moderate form contrast even at background distances due to their vertical form against the horizontal ground plain. Form and texture contrast would be moderate. One of the two towers would penetrate the ridgeline of the mountains in the background. As depicted in the simulations, the heliostat fields would also be partly visible, and exhibit diffuse reflection of the sky that could be very bright under some conditions, presenting color and texture contrast somewhat similar to a lake surface reflecting the sun. However, as discussed in detail farther below, form and color contrast would tend to be rendered irrelevant in comparison to the brightness of the glare of the solar receivers. Based on available information, staff concluded that at the range of distances characteristic of the SR 177 corridor (very roughly 8 - 10 miles to the nearest solar receiver), viewers would be within the range of strong, significant glare impacts from the SRSGs. The illumination from the SRSGs at the tops of the two solar towers would be clearly visible from KOP 1 and throughout the SR 177 corridor, causing visual distraction and exacerbating the contrast associated with the project facilities. The resulting visual contrast of this combination of strong glare and form contrast would be high (see the **Visual Resources Table 2**).

In addition to glare impacts of the SRSGs, staff is concerned with potential impacts of very bright, inadvertent direct solar reflections from the heliostats (DSRH) caused by stray mirrors, particularly during pre-operation mirror calibration and testing. During full operation, it is assumed that such stray reflections will not occur. However, the intensity of even very transitory ground-based DSRH events are such that they would cause discomfort glare and constitute a significant visual and glare impact. This impact is discussed further under CEQA Criterion D, Light and Glare, below; and is fully addressed in Condition of Certification **TRANS-7**, Heliostat Positioning and Monitoring Plan.

Project Dominance*:* Dominant. As described previously, staff concluded that viewers at KOP 1 and the SR 177 corridor would be within the range of significant glare impacts.

The brightness of the receivers would dominate attention, could not be ignored by the viewer, and could cause discomfort in views toward the project. The proposed project also would appear prominent given the location of the two solar towers within (a) the center of Chuckwalla Valley (north to south) and (b) the center of a primary field of view toward the Palen and Chuckwalla Mountains across the valley. Overall, project dominance would be high.

View Blockage: Moderate. Glare from the solar receivers would make views toward those portions of the Palen and Chuckwalla Mountains near the solar receivers uncomfortable. The receivers would thus effectively block views of the Chuckwalla and Palen Mountains in those portions of the view in which the receivers are seen. The resulting view blockage would be moderate.

Overall Visual Change: Moderately high. Based on available information, from KOP 1, the values for visual contrast, project dominance, and view blockage, when taken together, constitutes a high level of overall visual change.

Visual Impact Significance: Adverse and significant. When considered within the context of the overall moderately high visual sensitivity of viewers in this portion of the viewshed, the moderately high visual change that would be perceived from KOP 1 would cause an adverse and significant visual impact.

Mitigation: Given the large scale of the impact area and the height and glare of the solar towers, no available mitigation measures were identified that would be adequate to mitigate the significant visual impacts to less than significant levels. However, if the amended project is approved, Energy Commission staff recommends the following conditions of certification to minimize structure contrast and lighting and glare impacts to the extent possible: **VIS-1**, Surface Color Treatment of Structures; **VIS-2**, Revegetation of Disturbed Soil Areas; **VIS-3**, Temporary and Permanent Exterior Lighting. Conditions of Certification **VIS-1**, **VIS-2**, and **VIS-3** are from the Commission Decision. Staff also recommends Condition of Certification **TRANS-7** to address inadvertent DSRH glint impacts, both during and prior to project operation.

Residual Impact Significance After Mitigation. No mitigation measures were identified by Energy Commission staff to fully address impacts. Impacts would remain significant and unavoidable.

KOP 2 – Northwest of Desert Center/Big Wash (JTNP)

KOP 2 was selected to characterize the visual impact to recreationists accessing the Joshua Tree National Park, and is the second nearest location to the project within the JTNP after KOP 1. KOP 2 is located at the eastern edge of the hills west of Desert Center and SR 177, approximately 13 miles northeast of the project site and approximately 15 miles from the nearest SRSG. The view is across the Chuckwalla Valley to the southeast and is depicted in **Visual Resources Figure 5A**. This location provides an open and unobstructed view of the site that would be experienced by recreationists seeking an off-road and backcountry recreational experience. The foreground to middleground terrain is flat and supports sparse desert scrub vegetation. The existing landscape appears predominantly natural in appearance and is absent any built features. Visible in the background are the angular forms of the Palen and Chuckwalla Mountains.

Visual Quality: Moderate. The foreground to middleground views encompass a broad, open and undeveloped landscape consisting of a relatively non-descript, flat, grass- and shrub-covered plain, back-dropped by the angular forms of the Palen Mountains (adjacent and to the east of the site). As depicted in the KOP, visual disturbance from human activity is relatively minimal in views toward the site from this portion of the viewshed (JTNP), which is visually isolated by terrain from the Eagle Mine and Hayfield pumping station to the north. The mountain range adds visual interest and contributes to the moderate rating for visual quality.

Viewer Concern: High. Viewers within the JTNP are considered by definition to have high viewer concern, and undisturbed scenery is a primary expectation of such viewers. In general, as the landscapes along the I-10 corridor and within the Chuckwalla Valley become more and more industrialized with the addition of built features with industrial character, opportunities for recreational experiences that offer expansive views of intact and natural-appearing desert landscapes are rapidly diminishing. Thus, the off-road, backcountry recreationists seeking unspoiled landscapes and a respite from the highly urbanized areas of Southern California to the west would be highly sensitive to the introduction of industrial character to this naturally appearing landscape, and would perceive such as an adverse visual change. Therefore, overall viewer concern is rated high.

Viewer Exposure: Moderately high. Site visibility is high in that the view of the site from KOP 2 is unobstructed. As described under KOP 1, although the site is quite distant from KOP 2, the brightness of glare from the SRSGs is expected to greatly accentuate the prominence, dominance and contrast of the project, even at such background distances. Although the precise level of brightness at this distance is not known, based on the information currently available, the SRSGs are anticipated to remain prominent at this viewing distance (15 miles). While the number of viewers would be low, the view duration would be extended, with uninterrupted views to the site from KOP 2 and its vicinity occurring for substantial distances at low travel speeds. The high visibility, low numbers of viewers and extended duration of view would result in moderately high viewer exposure.

Overall Visual Sensitivity: Moderately high. For viewers at KOP 2 and along nearby access roads, the moderately low visual quality combined with high viewer concern and moderately high viewer exposure result in an overall moderate-to-high visual sensitivity of the visual setting and viewing characteristics.

Visual Resources Figure 5B presents a visual simulation of the proposed project site and illustrates the visibility of the project area.

Visual Contrast: Moderate. From this KOP, form contrast of the towers would be low. Their vertical form would contrast with the predominantly horizontal lines of the setting and would penetrate the ridgeline of background mountains, drawing the eye, but their magnitude in the overall field of view would be subordinate to other features in the view. Taller power block features, including the air-cooling condensers, would also be visible but would present a subordinate level of form contrast. If the concern were the project structures alone, project contrast at this distance would be moderately low or low. However, as described previously in KOP 1, the brightness of the solar receivers would be sufficiently intense as to render other aspects of visual contrast secondary. Based on currently available information, this KOP, at a distance of approximately 14 miles from the nearest solar tower, is expected to lie outside the range of significant glare impact identified by staff. However, contrast from glare at this KOP is anticipated to remain moderate.

Project Dominance: Co-dominant. Based on available information, KOP 2 is believed by staff to be outside of the range of significant glare impacts from the SRSGs. However, they would remain evident as very bright, although small, points of light, which would contrast with the visual background and attract attention. The mirror fields would appear relatively inconspicuous at this distance, unless bright glint reflections occurred off mirrors under certain conditions. These conditions would be transitory however. With recommended Condition of Certification **TRANS-7**, glint effects would remain considerably less bright than the SRSGs. Overall project dominance would be co-dominant. Staff considers that SRSG brightness could remain at least moderate and co-dominant from KOP 2. (The reader is referred to **APPENDIX TT1 VISUAL SAFETY IMPACT ASSESSMENT** in the **TRAFFIC AND TRANSPORTATION** section of this document.)

View Blockage: Moderately low. At these distances, glare from the solar receivers would remain prominent in views looking toward the Palen and Chuckwalla Mountains. However, at this distance the proportion of the field of view affected by the project in its entirety remains quite small, as depicted in the simulation. From the vicinity of KOP 2, the solar towers would not block large portions of the Chuckwalla Valley floor, the background Palen and Chuckwalla Mountains, or the sky from view, but the towers would be higher and more prominent than the mountains in the nearby background, and their reflected sunlight would be apparent in views in the direction of the towers. Overall, the resulting view blockage from the effect of glare would be considered moderately low.

Overall Visual Change: Moderate. Based on available information, the values for visual contrast, project dominance, and view blockage, when taken together, constitute a moderate level of overall visual change.

Visual Impact Significance: Adverse and significant. Due to the location within JTNP, based on available information, when considered within the context of viewers' overall moderately high visual sensitivity, the moderate visual change that would be perceived from KOP 2 would represent an adverse and significant visual impact.

Mitigation: Given the large scale of the impact area, no available mitigation measures were identified that would be adequate to mitigate the potentially significant visual impacts to a less than significant level. However, if the amended project is approved, Energy Commission staff recommends the following conditions of certification to minimize structure contrast and lighting and glare impacts to the extent possible: **VIS-1**, Surface Color Treatment of Structures; **VIS-2**, Revegetation of Disturbed Soil Areas; **VIS-3**, Temporary and Permanent Exterior Lighting.

Residual Impact Significance After Mitigation: No measures were identified by Energy Commission staff to fully address impacts. Impacts would remain potentially significant and unavoidable.

KOP 3 – Eastbound Interstate 10

KOP 3 was selected to characterize the visual impact to motorists on I-10 in the immediate vicinity of the proposed project. KOP 3 is located on eastbound I-10, just east of the Corn Springs Road/I-10 eastbound on-ramp, approximately 0.5 mile west of the project site. The view is to the east as depicted in **Visual Resources Figure 6A.** Views from I-10 near the project provide an open and unobstructed view of the site. The foreground to middleground terrain is flat and supports sparse desert scrub vegetation. The existing landscape appears absent any built features and is natural in appearance. The project would be visible in the foreground. To the north and east of the site (background mountains in the image) are the Palen Mountains and Palen McCoy Wilderness. To the north and north-northwest of the site (beyond the frame of the image) are the Granite and southern end of the Coxcomb Mountains, and Joshua Tree National Park.

Visual Quality: Moderate. The foreground to middleground views from I-10 encompass a broad, open and predominantly undeveloped landscape consisting of a relatively non-descript, flat, grass- and shrub-covered plain, backdropped by the striking angular forms of the Palen Mountains and the more distant Granite and Coxcomb Mountains to the north. The mountain ranges add visual interest and contribute to the moderate rating for visual quality. Existing visual disturbances in the highway corridor include existing transmission lines, commercial uses of Desert Center, and the Red Bluff substation, under construction roughly 3.9 miles west of the project site.

Viewer Concern: Moderately high. Typically, viewer concern of highway motorists is considered moderate. However, as the landscapes along the I-10 corridor become more and more industrialized with the addition of built features with industrial character, opportunities for expansive views of natural appearing desert landscapes are rapidly diminishing. Combined with the high volume of travelers on I-10 (the primary travel corridor between Southern California and Phoenix) and viewer expectations of observing higher quality landscape features while traveling through a designated conservation area (CDCA), travelers would be highly sensitive to the introduction of industrial character to this naturally appearing landscape, which would be perceived as an adverse visual change. Therefore, overall viewer concern is rated moderately high.

Viewer Exposure: High. Site visibility is high in that the view of the site from KOP 3 is unobstructed at foreground viewing distances. The number of viewers is high and the view duration for motorists on I-10 would be extended, with uninterrupted sightlines to the site from I-10 extending out many miles of travel. The high visibility and number of viewers and extended duration of view would result in high viewer exposure.

Overall Visual Sensitivity: Moderately high. For viewers at KOP 3 and along I-10, the moderate visual quality combined with moderately high viewer concern and high viewer exposure result in an overall moderately high visual sensitivity of the visual setting and viewing characteristics.

Visual Resources Figure KOP 6B presents a visual simulation of the proposed project as viewed from KOP 3.

Visual Contrast: High. The proposed project would add prominent industrial features to the foreground landscape, including the prominent vertical forms of the solar towers, air-cooled condensers, heliostat fields, and nearby segment of the transmission line to the Red Bluff substation.

As depicted in the simulation of KOP 3 (**Visual Resources Figures 6B)**, form contrast of the towers alone would be very strong at this distance, their vertical form contrasting strongly with the predominantly horizontal lines of the existing valley floor landscape, and breaking the ridgeline of the Palen Mountains in the background. The 750-foot-tall towers would appear massive at this distance (approximately 1.5 mile to the nearest tower). For purposes of comparison, the solar towers would be the third-tallest structures in San Francisco, with a luminous receiver area of approximately 12 stories in height. From the vicinity of I-10, lower project features such as the air-cooling unit, transmission towers, and the heliostat fields would also be prominent, adding a further highly industrial character to views.

However, as described previously, form and color contrast of the towers would be rendered less relevant due to the extreme brightness of the solar receivers, which at this distance would be so bright that viewers would avoid looking directly at the towers. As discussed below under the “Criterion D, Light and Glare” subsection, at this distance (approximately 1.5 mile from the nearest tower) the receivers would appear roughly as large in magnitude within the viewer’s field of vision (subtended visual angle) as the sun, and would be sufficiently bright as to constitute a highly dominant and distracting visual feature. At this distance, the visual effect could thus be subjectively similar to two additional suns in the sky. Although the level of brightness would not cause physical harm to viewers’ vision, it would make the towers visually highly dominant, and would strongly disrupt the experience of the natural landscape. The resulting level of visual contrast due to glare would be high. In addition, high levels of diffuse sky reflection off the heliostats are anticipated during certain hours of the day, extending the area of high project contrast over large portions of the visual field.

Project Dominance: Dominant. At this distance, the solar receiver towers would exert strong scale dominance, as the only comparable vertical element within the immediate field of view in a setting characterized by flat, horizontal topography. The brightness of the solar receivers, however, would be the dominating visual element of the landscape, strongly demanding viewers’ attention. Overall project dominance would be high.

View Blockage: High. From the vicinity of KOP 4, glare from the solar receivers would intrude strongly into views in the direction of the Palen Mountains. In effect, the receivers would thus effectively block views of the Palen Mountains from this general area by distracting viewers, or causing them to avert their gaze. View blockage is thus considered high.

Overall Visual Change: High. From KOP 4, the values for visual contrast, project dominance, and view blockage, when taken together, constitutes a high level of overall visual change.

Visual Impact Significance: Adverse and significant. When considered within the context of the overall moderately high visual sensitivity of the existing landscape and viewing characteristics, the high visual change that would be perceived from KOP 4 would cause an adverse and significant visual impact.

Mitigation: Given the large scale of the impact area, no available mitigation measures were identified that would be adequate to mitigate the significant visual impacts to levels that would be less than significant. However, if the amended project is approved, Energy Commission staff recommends the following conditions of certification to minimize structure contrast and lighting and glare impacts to the extent possible: **VIS-1**, Surface Color Treatment of Structures; **VIS-2**, Off-Site Landscape Screening; **VIS-3**, Revegetation of Disturbed Soil Areas; **VIS-4**, Temporary and Permanent Exterior Lighting. Staff also recommends Condition of Certification **TRANS-7** to address inadvertent DSRH glint impacts.

Residual Impact Significance After Mitigation: No measures were identified by Energy Commission staff to fully address impacts. Impacts would remain significant and unavoidable.

KOP 4 – Westbound Interstate 10

Like KOP 3, KOP 4 represents the experience of motorists on I-10 in the immediate vicinity of the proposed project. For purposes of comparison to KOP 3, which is at middleground distance, KOP 4 is located on westbound I-10, approximately 6.4 miles southeast of the project site, at background distance. The view is to the northwest as depicted in **Visual Resources Figure 7A**. Viewing conditions are as described previously under KOP 3.

Visual Quality, Viewer Concern, and Viewer Exposure: Visual quality, viewer concern, and viewer concern from I-10 near the project site were described above under KOP 3.

Overall Visual Sensitivity: Moderately high. As under KOP 3, for viewers at KOP 4 and along I-10, the moderate visual quality combined with moderately high viewer concern and high viewer exposure result in an overall moderate-to-high visual sensitivity of the visual setting and viewing characteristics.

Visual Resources Figure 7B presents a visual simulation of the proposed project as viewed from KOP 4.

Visual Contrast: High. As described under KOP 3, the proposed project would add prominent industrial features to the landscape of I-10, including the prominent vertical forms of the solar towers, air-cooled condensers, heliostat fields, and nearby segment of the transmission line to the Red Bluff substation. From background distances such as KOP 4, the form contrast of the project features would be moderate. However, based on available information, even at this distance (6.4 miles from project), SRSG glare is anticipated to be strong, demanding viewers' attention, eliciting visual fixation and afterimages, and representing a high degree of contrast. In addition, high levels of bright, diffuse glare off portions of the heliostat fields are anticipated during certain hours of the day, extending high project contrast over a large portion of the field of view.

Project Dominance: Dominant. Dominance of project features alone would be moderate. However, even at this background distance the level of glare from the SRSGs would strongly demand viewers' attention and could not be ignored.

View Blockage: High. From the vicinity of KOP 4, glare from the solar receivers would intrude into views in the direction of the Eagle and Coxcomb Mountains, strongly altering the perception of the natural landscape. In effect, the receivers would thus tend to block views of the Eagle and Coxcomb Mountains from this general area by distracting viewers or causing them to avert their gaze. View blockage is thus considered high.

Overall Visual Change: High. From KOP 4, the values for visual contrast, project dominance, and view blockage, when taken together, constitute a high level of overall visual change.

Visual Impact Significance: Adverse and significant. When considered within the context of the overall moderately high visual sensitivity of the existing landscape and viewing characteristics, the high visual change perceived from KOP 4 would cause an adverse and significant visual impact.

KOP 5 – Corn Springs Road/Chuckwalla Mountains Wilderness

KOP 5, **Visual Resources Figure 8A,** depicts the view from Corn Springs Road, within the Chuckwalla Mountains Wilderness. Corn Springs Road provides access to the wilderness area, and to the BLM Corn Springs Campground, a popular recreational destination located, atypically, within the wilderness area. The campground, noted for a palm oasis and exceptional archaeological features, lies outside of the viewshed of the PSEGS, visually isolated by intervening mountains. KOP 5 is located in the northeast portion of the wilderness area, approximately 3.5 miles southwest of the project site, and roughly 4.7 miles from the nearest solar tower (middleground distance). Open and unobstructed views of the site would be experienced both by recreationists seeking the backcountry recreational wilderness experience and by visitors enroute to and from the Corn Springs Campground. Views in the WA are characterized by panoramic vistas of the project site, Chuckwalla Valley and beyond, seen from an elevated position. The middleground to background view encompasses the flat valley floor, backdropped by the rugged and vivid forms of the Palen, Granite and Coxcomb Mountains. From this vantage point, the existing landscape appears predominantly natural in appearance and is absent any noticeable built features except for the thin linear form of I-10 that passes through the valley.

Visual Quality: Moderately high. As depicted in **Visual Resources Figure 8A**, the middleground to background panoramic vistas from even the lower north-facing foothills of the Chuckwalla Mountains Wilderness encompass broad expanses of the low-lying Chuckwalla Valley, dry lake bed, and bajadas ringed by rugged, angular mountain ranges that appear to rise abruptly from the flat valley floor. Visual integrity of the dramatic desert landscape is relatively high. The Sunrise Powerlink transmission lines, development of Desert Center and the thin line of I-10 are visible in the distance but remain subordinate within the view. The elevated perspective from KOP 5 thus provides a panoramic overview of the relatively intact valley landscape over vast distances. Overall visual quality is moderately high.

Viewer Concern: High. Backcountry recreationists seeking the desert wilderness experience would expect to find viewing opportunities that offer expansive views of intact and natural appearing desert landscapes with minimal if any industrial character. These backcountry and wilderness visitors would be highly sensitive to the introduction of industrial character to this naturally appearing landscape, and would perceive such additions as an adverse visual change. Therefore, overall viewer concern is rated high.

Viewer Exposure: Moderately high. Viewer exposure is high in that the view toward the project site from KOP 5 is both unobstructed and elevated. From this elevated position, expansive, panoramic views of the surface of the valley floor and project site are visible in the distance below. The large scale of the project would render the project highly prominent in the field of view to the north, even at a 5-mile viewing distance. While the number of viewers would be low, the view duration would be extended from throughout the northeastern portion of the Chuckwalla Mountains Wilderness. Viewer numbers would be somewhat higher than typical in wilderness areas due to use of the campground and accessibility provided by Corn Springs Road. The high visibility, low numbers of viewers and extended duration of view would result in moderately high viewer exposure.

Overall Visual Sensitivity: Moderately high. For viewers at KOP 5 and other nearby viewing areas within the Chuckwalla Mountains Wilderness, the moderately high visual quality combined with high viewer concern and moderately high viewer exposure result in overall moderately high visual sensitivity.

Visual Resources Figure 8B presents a visual simulation of the proposed project form KOP 5.

Visual Contrast: High. The proposed project would convert a substantial portion of the existing, natural-appearing desert valley landscape to an industrial facility that would be characterized (at a five-mile viewing distance) by geometric forms and prominent horizontal and vertical lines and industrial colors and surface textures. The project, occupying 5.9 square miles of the valley floor, would dominate a large portion of the northward field of view. Because of the elevated perspective, a majority of the facility would be visible including both towers, the power blocks, heliostat field, and transmission line, though at this viewing distance (approximately five miles) many structural details would not be discernible. As suggested in the simulation, the heliostat fields, viewed from an elevated position, would display large areas of diffuse reflection somewhat like a lake surface, which would vary in brightness with hour and season. Overall the introduced industrial characteristics are highly contrastive with the existing landscape.

However as discussed previously, the brightness of the solar receivers would be sufficiently intense as to render other aspects of visual contrast less relevant. The receivers, visible in this KOP at middleground to background distance, would be perceived as extremely bright light sources demanding attention and causing visual distraction when in the field of view. As such, visual contrast of the project from KOP 5 is considered high.

Project Dominance: Dominant. The proposed project would appear prominent given the spatial prominence of the proposed facility within (a) the center of Chuckwalla Valley (north to south) and (b) the center of a primary field of view toward the Coxcomb, Granite, and Palen Mountains across the valley. The proposed project would dominate views of the broad valley floor surface and strongly intrude into views of the background mountains. Overall, the solar receivers would dominate the visual environment, could not be ignored, and would cause discomfort in views in the direction of the towers over a broad area. Overall project dominance would be high.

View Blockage: Moderately high. Glare from the solar receivers would intrude strongly into views northward from within a broad area of the northeastern Chuckwalla Mountains Wilderness, prominently altering their character from a natural desert landscape to a predominantly industrial one. A From the vicinity of KOP 5, the heliostat fields would also block from view a noticeable and central portion of the Chuckwalla Valley floor. The resulting view blockage would be moderately high.

Overall Visual Change: High. The project would demand attention, could not be overlooked, and would be dominant in the landscape. From KOP 5, the values for visual contrast, project dominance, and view blockage, when taken together, would constitute a high level of overall visual change.

Visual Impact Significance: Adverse and significant. When considered within the context of the overall moderately high visual sensitivity of the existing landscape and viewing characteristics, the high visual change that would be perceived from KOP 5 would cause a significant and unavoidable visual impact.

Mitigation: Given the large scale of the impact area, no available mitigation measures were identified that would be adequate to mitigate the significant visual impacts to levels that would be less than significant. However, if the amended project is approved, Energy Commission staff recommends the following conditions of certification to minimize structure contrast and lighting and glare impacts to the extent possible: **VIS-1**, Surface Color Treatment of Structures; **VIS-2**, Revegetation of Disturbed Soil Areas; **VIS-3**, Temporary and Permanent Exterior Lighting.

Residual Impact Significance After Mitigation: No measures were identified by Energy Commission staff to fully address impacts. Impacts would remain significant and unavoidable.

KOP 6 – Palen McCoy Wilderness

KOP 6 represents the visual impact to recreationists in the Palen McCoy Wilderness. KOP 6 is located on a ridge in the southwestern portion of the wilderness area. The elevated view to the southwest is depicted in **Visual Resources Figure 9A**. This location provides an open and unobstructed elevated view of the site that would be experienced by recreationists seeking the backcountry wilderness experience, with panoramic vista views of the Chuckwalla Valley and beyond. The middleground to background view encompasses the flat valley floor, backdropped by the rugged, angular forms of the Chuckwalla Mountains. From this elevated vantage point, the existing landscape appears predominantly natural in appearance and is absent any noticeable built features except for the thin linear form of I-10 that passes through the valley and some rectilinear fields of irrigated agriculture whose green color contrasts with the surrounding area.

Visual Quality: Moderately high. The middleground to background panoramic views from the ridges along the southern flanks of the Palen McCoy Wilderness encompass broad expanses of the Chuckwalla Valley, ringed by rugged, angular mountain ranges that rise abruptly from the flat valley floor, contributing a vivid, dramatic element. Visual integrity of the desert landscape is high, with minimal intrusions of visually discordant built features to interrupt the distinctive basin-range physiography. The elevated perspective of KOP 6 enables views of considerable visual interest, and overall visual quality is rated moderately high.

Viewer Concern: High. Backcountry recreationists seeking the desert wilderness experience would expect to find viewing opportunities that offer expansive views of intact and natural appearing desert landscapes with minimal if any industrial character, particularly within the California Desert Conservation Area. These backcountry and wilderness visitors would be highly sensitive to the introduction of industrial character to this naturally appearing landscape, and would perceive such additions as an adverse visual change. Therefore, overall viewer concern is rated high.

Viewer Exposure: Moderate. Site visibility is high in that the view of the site from KOP 6 is unobstructed at a middleground viewing distance and the site is central to the field of view. While the number of viewers would be very low, the view duration would be extended from the vista viewpoints along the southern ridges of the Palen McCoy Wilderness. The high visibility, very low numbers of viewers and extended duration of view would result in moderately high viewer exposure.

Overall Visual Sensitivity: Moderately high. For viewers at KOP 6 and other nearby viewing areas within the Palen McCoy Wilderness, the moderately high visual quality combined with high viewer concern and moderate viewer exposure result in an overall moderately high visual sensitivity.

Visual Resources Figure 9B presents a visual simulation of the proposed project from KOP 6.

Visual Contrast: High. The proposed project would convert a substantial portion of the existing, natural-appearing landscape to an industrial facility that would be characterized by rectilinear and geometric forms with strong horizontal and vertical lines and industrial and reflective surfaces. Because of the elevated perspective, the entire facility would be visible, including both towers, the power blocks, heliostat field, and transmission line. These introduced industrial characteristics would contrast strongly in form, line, color and texture with the existing landscape.

As described previously, the brightness of the solar receivers would be sufficiently intense as to render other aspects of visual contrast less relevant. From this typical KOP, the solar receivers would be visible at a distance of between 5 and 6 miles and would be perceived as extremely bright light sources demanding attention and contrasting strongly with the natural background landscape when in the field of view. As such, visual contrast of the project from KOP 6 is considered high.

Project Dominance: Dominant. The proposed project would appear highly prominent given the great spatial extent of the proposed facility within (a) the center of Chuckwalla Valley (north to south) and (b) the center of a primary field of view toward the southwest and the Chuckwalla Mountains across the valley. The proposed project would occupy a large proportion of the valley floor as seen from south- and west-facing slopes in the southernmost area of the Palen McCoy Wilderness. Most significantly, the glare of the solar receivers would dominate the visual environment over a substantial portion of both lowlands and highlands in the south- and west-facing areas of the wilderness. The glare of the SRSGs could not be ignored, and would dominate views in the direction of the towers. Overall project dominance would be high.

View Blockage: Moderately high. Glare from the solar receivers would intrude strongly into views in the direction of the project from within a large area of the wilderness. In addition, from elevated viewpoints such as KOP 6, the project facilities would block from view a substantial and central portion of the Chuckwalla Valley floor. The resulting view blockage would be moderately high.

Overall Visual Change: High. The project would demand attention, could not be overlooked, and would be dominant in the landscape. From KOP 6, the values for visual contrast, project dominance, and view blockage, when taken together, would constitute a high level of overall visual change.

Visual Impact Significance: Adverse and significant. When considered within the context of the overall moderately high visual sensitivity of the existing landscape and viewing characteristics, the high visual change that would be perceived from KOP 6 would cause an adverse and significant visual impact.

Mitigation: Given the large scale of the impact area, no available mitigation measures were identified that would be adequate to mitigate the significant visual impacts to levels that would be less than significant. However, if the amended project is approved, Energy Commission staff recommends the following conditions of certification to minimize structure contrast and lighting and glare impacts to the extent possible: **VIS-1**, Surface Color Treatment of Structures; **VIS-2**, Revegetation of Disturbed Soil Areas; **VIS-3**, Temporary and Permanent Exterior Lighting.

Residual Impact Significance After Mitigation: No measures were identified by Energy Commission staff to fully address impacts. Impacts would remain significant and unavoidable.

Visual Resources Table 2
KOP Ratings: Visual Sensitivity/Visual Change and Impact Significance under CEQA Criterion C

KOP No.	VISUAL SENSITIVITY (Existing Condition)						
			Viewer Exposure				
	Visual Quality	Viewer Concern	Visibility	No. of Viewers	Duration of View	Overall Viewer Exposure	Overall Visual Sensitivity
1 SR 177 Corridor/ Coxcomb Mt. (JTNP)	Moderately low	High	High	Moderat e	High	Moderately high	Moderately high
2 Northwest of Desert Center/ Big Wash (JTNP)	Moderate	High	High	Low	High	Moderate to High	Moderately high
3 Eastbound I-10	Moderate	Moderately high	High	High	High	High	Moderately high
4 Westbound I-10	Moderate	Moderately high	High	High	High	High	Moderately high
5 Corn Springs Road/ Chuckwalla Mountains Wilderness	Moderately high	High	High	Low	High	Moderately high	Moderately high
6 Palen McCoy Wilderness	Moderate high	High	High	Very Low	High	Moderate	Moderately high

KOP No.	VISUAL CHANGE (Project Effect)			
	Contrast	Dominance	View Blockage	Overall Visual Change
1 SR 177 Corridor/ Coxcomb Mt. (JTNP)	High	Dominant	Moderate	Moderately high
2 Northwest of Desert Center/ Big Wash (JTNP)	Moderate	Co-Dominant	Moderately low	Moderate
3 Eastbound I-10	High	Dominant	High	High
4 Westbound I-10	High	Dominant	High	High

5 Corn Springs Road/ Chuckwalla Mountains Wilderness	High	Dominant	Moderately high	High
6 Palen McCoy Wilderness	High	Dominant	Moderately high	High

KOP No.	**KOP VISUAL IMPACT SIGNIFICANCE DETERMINATION – (CEQA Criterion C)**			
	Overall Visual Sensitivity	**Overall Visual Change**	**Visual Impact Significance**	**Mitigation (See Staff Proposed KOP Visual Mitigation Measures)**
1 SR 177 Corridor/ Coxcomb Mt. (JTNP)	Moderately high	High	Significant	VIS-1, -2, -3, -4 Significant and unavoidable
2 Northwest of Desert Center/ Big Wash (JTNP)	Moderately high	Moderate	Significant	VIS-1, -2, -3, -4 Significant and unavoidable
3 Eastbound I-10	Moderately high	High	Significant	VIS-1, -2, -3, -4 Significant and unavoidable
4 Westbound I-10	Moderately high	High	Significant	VIS-1, -2, -3, -4 Significant and unavoidable
5 Corn Springs Road/ Chuckwalla Mountains Wilderness	Moderately high	High	Significant	VIS-1, -2, -3, -4 Significant and unavoidable
6 Palen McCoy Wilderness	Moderately high	High	Significant	VIS-1, -2, -3, -4 Significant and unavoidable

Non-operation and Facility Closure

After the end of the project’s useful life, owner would be required to close the facility. The complete removal of the facility would leave a very prominent visual impact over the entire site due to the strong color contrast created between graded, disturbed soil areas and undisturbed soil areas near the project site. In addition, revegetation of areas in this desert region are difficult and generally of limited success. Thus, visual recovery from land disturbance of the facility closure would likely occur only over a very long period of time.

D. Light And Glare

"Would the project create a new source of substantial light or glare that would adversely affect daytime or nighttime views in the area?"

Glare is defined as a difficulty in seeing in the presence of bright light, and is caused by a significant ratio of luminance between the task (that which is being looked at) and the glare source. Glare can be generally divided into two types, **discomfort** glare and **disability** glare. Discomfort glare results in an instinctive desire to look away from a bright light source or difficulty in seeing a task. Disability glare renders the task impossible to view, such as when driving westward at sunset.

To analyze the potential for significant glare impacts, staff relied on SRSG luminance data provided by the project owner, as well as past technical studies of the anticipated luminance properties of solar receivers, conducted by staff for other projects. According to data provided by the project owner in response to Data Request Set 3, the SRSGs would have a maximum luminance of $1X10^6$ cd/ m^2. On that basis, staff concluded that the SRSGs would appear very bright and distracting, demanding visual attention and eliciting visual fixation to distances of 10 miles or greater, but would not be a source of either discomfort or disability glare. However, based on the luminance level cited and an analysis of the project site and viewing conditions, staff concluded that SRSG brightness would be very high, dominating the landscape when in the field of view, demanding viewers' attention, and exhibiting high levels of visual contrast to distances of 10 miles or greater. Under conditions of moderate or high overall visual sensitivity of viewers, this level of contrast was considered a significant adverse visual impact.

(Please refer to the detailed discussion of glare effects found in the **TRAFFIC AND TRANSPORTATION** section, **APPENDIX TT1 – VISUAL SAFETY IMPACT ASSESSMENT)**.

Non-Mirror Facility Surfaces:

No. Surfaces of the facilities of the PSEGS project (excluding the solar receivers and the mirrored surfaces of the heliostats, which are discussed below) have the potential to introduce reflected glare into the visual environment. With the effective implementation of Condition of Certification **VIS-1** from the PSPP Commission Decision, the project would use colors and finishes on surfaces that do not cause excessive glare and would be in harmony with the project's desert environment (with the exception of the heliostat mirrors and SRGSs, discussed below).

Heliostats:

Yes. Staff is concerned with the potential for inadvertent direct solar reflections from the heliostats (DSRH), both during and prior to project operation, particularly during the project's mirror-calibration phase. DSRH are judged to be in excess of the threshold for discomfort glare for minimum viewing distances of 10 miles. As such staff recommends that all reasonable actions be taken to mitigate these events during site construction, testing and operations. Recommended measures to address DSRH can be found in Condition of Certification **TRANS-7**, Heliostat

Positioning and Monitoring Plan. This condition is anticipated to reduce DSRH impacts to less-than-significant levels.

When observed from a distance during operations the heliostat fields generally reflect a portion of the sky to the viewer. In the region closer to the tower the heliostats often reflect a portion of the sky in greater proximity to the sun and these regions appear brighter and whiter producing a low to moderate level of sustained glare depending on viewing geometry and range. Elsewhere in the mirror field, reflections of the sky are visible ('lake effect'). These heliostat reflections from the mirror fields as a whole would be prominent and would contribute to the overall visual contrast of the project as seen from various KOPs, as discussed under Criterion C, above. However, this type of heliostat glare would not cause either disability or discomfort glare and is not considered a significant glare impact here under Criterion D.

Solar Power Towers/SRSGs:

Yes. Energy Commission staff has determined that the visual impact of glare from the SRSGs will have a significant and unavoidable visual impact.

The principal anticipated project visual impact would result from glare of the SRSGs. For purposes of this analysis, the potential for significant glare impacts have relied on SRSG luminance data provided by the project owner, as well as past technical studies of the anticipated luminance properties of solar receivers, conducted by staff for other projects. According to data provided by the project owner in response to Data Request Set 3, the SRSGs would have a maximum luminance of $1X10^6$ cd/m^2. On that basis, staff concluded that the SRSGs would appear very bright and distracting, demanding visual attention and eliciting visual fixation to distances of 10 miles or greater, but would <u>not</u> be a source of either discomfort or disability glare. However, based on the anticipated luminance level cited and an analysis of the project site and viewing conditions, staff concluded that SRSG brightness would appear very high, dominating the landscape when in the field of view, demanding viewers' attention, and exhibiting high levels of visual contrast to distances of 10 miles or greater. Under conditions of moderate or high overall visual sensitivity of viewers, this level of contrast was considered a significant adverse visual impact.

Staff is also concerned with potential glare from shield structures located directly above and below the SRSGs. These reflective structures shield the tower support structure from heat of stray heliostat reflections. If inadvertently lit by stray mirror reflections, these surfaces have the potential to act as large glare sources and, because they are reflective, have the potential to be brighter glare sources than the SRSGs themselves. If inadvertently lit in this way, the shields would contribute to a larger and brighter combined glare source than the SRSGs alone. However, with recommended Condition of Certification **TRANS-7**, this impact could be avoided.

Night Lighting and FAA Safety Lighting:

No, with recommended conditions. Nighttime light pollution could result from project operational lighting, and from FAA warning lighting required on the solar towers. With effective implementation of light trespass mitigation measures as described in Condition of Certification **VIS-4** (VIS-3 from the Commission Decision), the project's off-site operation-related lighting impacts, excluding FAA safety lighting, would be less than significant. Condition of Certification **VIS-4** requires a comprehensive lighting plan be submitted to Riverside County for review and comment and to the Energy Commission compliance project manager (CPM) for review and approval. Staff recommends Condition of Certification **VIS-4** to ensure full compliance and verification of night lighting measures.

The addition of the aviation safety lighting would alter the nighttime appearance of the project area and would be visible in the night sky due to the height of the towers and the number of lights required by the towers' size. The brightest FAA-required lighting, of medium- or high-intensity white flashing lights, would apply during the day and twilight. At night, these would be replaced by less bright, flashing red safety lighting. Due to the height of the towers, FAA could require either high-intensity flashing white lights or non-luminous marking in addition to medium-intensity flashing white lights for daytime and twilight use. Staff observes that during daytime operation, both high-intensity FAA lighting *and* non-luminous marking would tend to be visually obscured by the much greater brightness of SRSG glare. Since views in the direction of the solar towers during daytime would tend to cause viewers to avert their gaze, both the safety lighting and tower marking would be of less importance than the brighter SRSG glare.

Nighttime light pollution impacts would be of particular concern to visitors to the Palen/McCoy WA, the Chuckwalla Mountains WA, and the JTNP. The pristine, completely unlit night sky is part of the attraction of virtually all WAs within the California desert, and is often cited as a valued attraction of the desert for campers (IDSA, 2010). However, staff concluded that night light pollution effects of the project, including night-time FAA lighting, with appropriate mitigation measures as described in Condition of Certification **VIS-4**, would not be substantial beyond background distances of very roughly 4 or 5 miles. The project would be visible from the portions of Palen/McCoy and Chuckwalla Mountains WAs that lie within this estimated radius of substantial night lighting effect. Camping is permitted throughout the WAs and it is assumed that camping may occur at undesignated sites within 4 miles of the project site. The Corn Springs Campground is located on Corn Springs Road approximately five miles southwest of the project site, in an east-west canyon that screens views of the project site from the campground. Therefore, campers at the Corn Springs Campground would not be affected by project night lighting. Project lighting effects would potentially be more pronounced to WA visitors within 4 miles of the project. With Condition of Certification **VIS-4**, off-site effects of bright operational lighting of the power block would be mitigated to a less-than-significant level. Therefore, the primary nighttime lighting effect to such WA visitors would result from required red FAA nighttime safety lighting. This would be visible in campers' night sky views, which would no longer have a pristine, unlit character and become more urban. The safety lighting would not, however, represent a very bright or highly distracting light source. It was assumed that campers with concern for pristine, completely unlit night skies could seek that experience in more remote locations of the WAs. This, together with the fact that the number of visitors to the WAs is believed to be low, leads staff to the conclusion that night lighting impacts to visitors in the WAs would be less-than-significant.

Two nighttime simulations of the PSEGS, prepared by the project owner, are reproduced at the end of this section as **Visual Resources Figures 10A and 10B, and 11A and 11B.** Staff comments on these simulations may be found under staff responses to intervenor comments, below. These and other night simulations may be found in the project owner's *Joshua Tree National Park Visual Resources Analysis Report,* dated May 31, 2013 (Palen 2013v).

CUMULATIVE IMPACTS AND MITIGATION

A project may result in a significant adverse cumulative impact where its effects are cumulatively considerable. "Cumulatively considerable" means that the incremental effects of an individual project are significant when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects (Cal. Code Regs., tit. 14, § 15130).

Cumulative impacts to visual resources would occur where project facilities occupy the same field of view as other built facilities or impacted landscapes, and an adverse change in the visible landscape character is perceived. In some cases, a cumulative impact could also occur if a viewer perceives that the general visual quality or landscape character of a localized area (Chuckwalla Valley or I-10 corridor) or larger region (California Desert District) is diminished by the proliferation of visible structures or construction effects, even if the changes are not within the same field of view as existing (or future) structures or facilities. The result is a perceived "industrialization" of the existing landscape character.

There is the potential for substantial future development in the Chuckwalla Valley area, along the I-10 corridor and throughout the California Desert District. As stated in the Application for Certification for the previously approved Solar Millennium Palen Solar Power Project at the project site (AFC, Page 5.15-20): *"If all the [cumulative projects] were to be implemented, the projects would convert many thousands of acres along the I-10 corridor between roughly Desert Center and Blythe from undeveloped desert viewshed to a more industrialized appearance."* Analysis of cumulative impacts is based on data provided in the Cumulative Scenario section and includes:

- Cumulative Impacts Figure **1,** I-10 Corridor Existing and Future/Foreseeable Projects along the I-10 Corridor (Eastern Riverside County) **Executive Summary Attachment A – Tables 1, 2, and 3**
- **Executive Summary Attachment A – Table 1**, Existing Projects along the I-10 Corridor (Eastern Riverside County)

The analysis in this section first defines the geographic area over which cumulative impacts to visual resources could occur. The cumulative impact analysis then describes the potential for cumulative impacts to occur as a result of implementation of the proposed project along with the listed local and regional projects.

Cumulative impacts could occur if implementation of the PSEGS would combine with those of other local or regional projects. PSEGS is potentially associated with two types of cumulative impact:

1. Cumulative impacts within the project viewshed (local projects within the viewshed of PSEGS as defined by staff), essentially comprising existing and foreseeable future projects in the Chuckwalla Valley and the nearby stretches of I-10 and SR 177; and

2. Cumulative impacts of foreseeable future solar, renewable and other energy and development projects within the I-10 Corridor (beyond the local viewshed), and other broad basin of the project's affected landscape type, or the California Desert District as a whole (regional projects).

CUMULATIVE VISUAL IMPACTS WITHIN THE PROJECT VIEWSHED

The following discussion of cumulative impacts will address PSEGS's contribution to cumulative impacts within the context of the existing cumulative conditions and within the context of future foreseeable projects.

There has been minimal development and/or industrialization of the project landscape within PSEGS's viewshed. Four existing projects fall within the viewshed of PSEGS including Interstate 10, the West-wide Section 368 Energy Corridor, the Eagle Mountain/Hayfield Pumping Plant, and the Kaiser (Eagle) Mine (see **Executive Summary Attachment A – Table 1** and **Executive Summary Attachment A – Figure 1** in the Cumulative Scenario section). Interstate 10 is visible as a linear, horizontal feature in the landscape but does not possess industrial character (complex forms or lines) on the scale of an energy facility such as PSEGS. The West-wide Section 368 Energy Corridor is a designation that implies the possibility of future linear projects within the corridor. However, the actual corridor designation does not impart any visual impact that could be considered in a cumulative context. The Eagle Mountain/Hayfield Pumping Plant, while potentially visible within the field of view of PSEGS (at a distance of slightly over 14 miles), is minimally noticeable at the distant margin of the viewshed limit. Views of much of the inactive open-pit Kaiser/Eagle Mine are screened from the project site by intervening hills. The remainder of the Kaiser Mine, located approximately 15 miles east of the project site, is minimally noticeable at the distant margin of the viewshed limit. Therefore, given the relative lack of perceptible industrial development (or development with characteristics similar to that of the proposed project) that has occurred within the PSEGS viewshed, PSEGS would not cause a cumulatively significant effect within the context of existing cumulative conditions.

The cumulative contribution of PSEGS must also be considered within the context of future foreseeable projects, including future projects within the project area and future projects within the larger contexts of the I-10 corridor and the California desert as a whole.

Executive Summary Attachment A – Table 2 and **Executive Summary Attachment A – Figure 1** in the Cumulative Scenario section list 37 future foreseeable projects that would be located with PSEGS's viewshed including:

- Devers-Palo Verde 2 Transmission Line Project
- Desert Southwest Transmission Line
- Green Energy Express Transmission Line Project
- Blythe Energy Project Transmission Line
- Eagle Mountain Pumped Storage Project
- Eagle Mountain Landfill
- Eagle Mountain Wind Project
- Graham Pass Wind Project
- Genesis Solar Energy Project
- Chuckwalla Solar I
- Desert Sunlight
- Desert Lily Soleil
- Desert Center 50
- Sol Orchard
- Silverado Power I, II, III
- Desert Harvest
- LH Renewables Riverside County Type II
- EnXco
- Blythe Energy Project II
- Blythe Solar Power Generation Station 1
- Blythe Mesa Solar I
- Milpitas Wash
- Sonoran West
- Mule Mountain Solar
- Mule Mountain III
- Desert Quartzite
- Nextlight Quartzite
- Palo Verde Mesa Solar Project
- La Posa Solar Thermal
- Three Residential (Blythe)

- 12 Residential Developments (Blythe)
- Four Commercial Projects (Blythe)
- Intake Shell
- Chuckwalla Valley Raceway
- Red Bluff Substation
- Colorado River Substation Expansion
- Wileys Well Communication Tower

While most of these projects are energy projects that would share similar industrial visual characteristics with PSEGS, all 37 projects would contribute to the conversion of natural desert landscapes to landscapes with prominent industrial character (complex industrial forms and lines and surface textures and colors not found in natural desert landscapes). Therefore, there would be a significant cumulative impact to visual resources from the combination of PSEGS and the 37 foreseeable projects listed above, both individually (each project plus PSEGS) and collectively (all 37 projects plus PSEGS).

REGIONAL CUMULATIVE VISUAL IMPACTS

Table 3 and Figure 2 in the Cumulative Scenario section also identify an additional nine future foreseeable energy projects along the I-10 corridor that would also contribute to the sense of industrialization of the desert landscape as one drives between Blythe and Desert Center or Los Angeles and Phoenix in a broader context. In a regional context, Table 1A and Figure 1 in the Cumulative Scenario section of the PSPP RSA (CEC 2010b) identified 125 renewable energy projects scattered throughout the California Desert Conservation Area. The number of projects shown in RSA Figure 1 is so great that there would not be a single major travel corridor through the Southern California desert that will not experience at least some visible “industrialization” due to the presence of nearby energy projects. As a result, travelers will encounter numerous industrial landscapes en-route to regionally and nationally significant desert destinations such as Anza-Borrego Desert State Park, the Salton Sea, Joshua Tree National Park, Mojave National Preserve, Death Valley National Park, and the Colorado River. Therefore, as a result of this collective industrialization of the conservation area landscapes, PSEGS would contribute a significant cumulative visual impact to visual resources in combination with foreseeable renewable projects in the California desert.

OVERALL CUMULATIVE IMPACT CONCLUSION

PSEGS would not result in a cumulative visual impact in the context of existing cumulative conditions. However, PSEGS’s contribution to the visible industrialization of the desert landscape would be cumulatively considerable and constitute a significant visual impact when considered with future foreseeable projects, both within the project viewshed and in a broader context that encompasses the whole of the California Desert Conservation Area.

COMPLIANCE WITH APPLICABLE LORS

The proposed project would be subject to the laws, ordinances, regulations, and standards (LORS) of the U.S. Government (Bureau of Land Management – BLM) and environmental laws of the State of California. Because the PSEGS would be located entirely on land managed by the BLM, the project would not be subject to the County of Riverside's LORS. However, staff has included a discussion of the project's consistency with the visual resources goals and objectives of Riverside County since these LORS informed staff's CEQA analysis of the project and indicate the importance of open space and scenic resources to the county. Consistency with these LORS is summarized in the following paragraphs and presented in more detail in **Visual Resources Table 3**.

COMPLIANCE WITH FEDERAL LORS

The project was found to be in compliance with the impact disclosure requirements of the California Desert Conservation Area (CDCA) Plan through the visual impact analysis presented here and in the BLM DEIS for this project.

COMPLIANCE WITH STATE LORS

The proposed project was found to be in compliance with the State Scenic Highway Program as pertains to compliance with scenic highway management objectives. The adjacent Interstate 10 is neither an eligible or a designated scenic highway under the state program.

CONSISTENCY WITH LOCAL LORS

Staff concludes that the project would be inconsistent with several County of Riverside requirements pertaining to protection/preservation of natural features, the visual character of the existing landscape, and scenic corridors. These requirements are found in LU 13.1 (preservation of scenic vistas), LU 13.3 (compatible appearance with surrounding environment), LU 20.1 (environmental character), LU 20.2 (avoid unnatural appearance) and LU 20.4 (open space and rural character). Staff also concludes that the project would be inconsistent with several landscaping requirements and pedestrian access requirements because landscaping is not proposed and pedestrians would not be allowed within the facility. However, given the arid conditions and remote location, this is understandable. These requirements are found in LU 4.1(c), LU 4.1(d), LU 4.1(m), LU 4.1(n), and LU 4.1(p).

Visual Resources Table 3
Laws, Ordinances, Regulations and Standards (LORs)

Applicable LORS	Description	Compliance/Consistency (assumes implementation of staff-recommended conditions of certification)
Federal		
California Desert Conservation Area (CDCA) Plan	PSEGS is located within the California Desert Conservation Area Plan, which is the BLM Resource Management Plan applicable to the project site (USDOI, 1980, as amended). The CDCA Plan did not include Visual Resource Management (VRM) inventory or management classes. However, a BLM-approved Visual Resource Inventory (VRI) was conducted in 2005 for the Devers-Palo Verde 2 Transmission Line Project EIS/EIR, which covers the project site. The PSEGS site is classified in the CDCA Plan as Multiple-Use Class (MUC) M (Moderate Use). Management of MUC M lands is based upon a controlled balance between higher intensity use and protection of public lands. This class provides for a wide variety of present and future uses such as mining, live- stock grazing, recreation, energy, and utility development. Class M management is also designed to conserve desert resources and to mitigate damage to those resources, which permitted uses may cause. The CDCA Plan includes a table (Table 1), which illustrates the types of allowable land uses by MUC Class. The table specifically includes Electrical Power Generation Facilities including Wind/Solar facilities. Guidance provided under this section allows for the authorization of such facilities within MUC M lands in compliance with National Environmental Policy Act (NEPA) requirements. New major electric transmission facilities may be allowed only within designated utility corridors. Existing facilities within designated utility corridors may be maintained and upgraded or improved in accordance with existing rights-of-way or amendments to right-of- way grants.	**Complies**. Solar electrical generation plants are specifically allowed for under the Multiple Use Class (MUC) Class M Guidelines if NEPA requirements are met.

Applicable LORS	Description	Compliance/Consistency (assumes implementation of staff-recommended conditions of certification)
State		
State Scenic Highway Program	The California State Department of Transportation (Caltrans) identifies a state system of eligible and designated scenic highways, which, if designated, are subject to various controls intended to preserve their scenic quality (California Streets and Highways Code, sections 260 through 263).	**Complies**. Highway I-10 within the project viewshed is not an eligible or designated State scenic highway.
Local		
Riverside County Integrated Plan LU-4 Relating to Project Design	LU 4.1 Requires that new developments be located and designed to visually enhance, not degrade the character of the surrounding area through consideration of the following concepts: c. Require that an appropriate landscape plan be submitted and implemented for development projects subject to discretionary review.	**Consistent.** The project owner does not propose to landscape the project site, and therefore would not submit a landscape plan for the project area. However, given the location of the project and the potential impacts to water and biological resources resulting from landscaping this location, staff concludes that this approach is appropriate.
	d. Require that new development utilize drought- tolerant landscaping and incorporate adequate drought-conscious irrigation systems.	**Consistent.** The project owner does not propose any landscaping, and therefore will not require irrigation or unnecessarily use water in the desert.
	l. Mitigate noise, odor, lighting, and other impacts on surrounding properties.	**Consistent.** All outdoor lighting at the project site will be the minimum required to meet safety and security standards and all light fixtures will be hooded to eliminate any potential for glare effects and to prevent light from spilling off the site or up into the sky. In addition, the light fixtures will have sensors and switches to permit the lighting to be turned off at times when it is not required. Condition of Certification **VIS-4** ensures compliance.
	m. Provide and maintain landscaping in open spaces and parking lots.	**Consistent.** The project footprint, as proposed, includes no open space, and parking facilities would be minimal. Planting and maintaining landscaping in the parking area of PSEGS, which would be inaccessible to the public, would require that water be used unnecessarily.
	n. Include extensive landscaping.	**Consistent.** Including extensive landscaping would not serve the project or surrounding viewers, and would require that water be used unnecessarily.

Applicable LORS	Description	Compliance/Consistency (assumes implementation of staff-recommended conditions of certification)
	o. Preserve natural features, such as unique natural terrain, drainage ways, and native vegetation, wherever possible, particularly where they provide continuity with more extensive regional systems.	**Consistent.** Required grading for the amended project would be substantially reduced compared to the PSPP.
	p. Require that new development be designed to provide adequate space for pedestrian connectivity and access, recreational trails, vehicular access and parking, supporting functions, open space, and other pertinent elements.	**Not Consistent.** The project would not be accessible by pedestrians, recreationists, or general vehicular travel.
	LU 4.2 Require property owners to maintain structures and landscaping to a high standard of design, health, and safety through the following: c. Promote and support community and neighborhood based efforts for the maintenance, upkeep, and renovation of structures and sites.	**Consistent**. The project owner would maintain the appearance of the project and ensure proper maintenance practices.
County Scenic Corridors	LU 13.1 Preserve and protect outstanding scenic vistas and visual features for the enjoyment of the traveling public.	**Not Consistent.** The project would not preserve or protect scenic vistas of the southern ridges of the Joshua Tree National Park and Palen McCoy Wilderness and the northeastern ridges of the Chuckwalla Mountains Wilderness, but would significantly impact them.
	LU 13.3 Ensure that the design and appearance of new landscaping, structures, equipment, signs, or grading within Designated and Eligible State and County scenic highway corridors are compatible with the surrounding scenic setting or environment.	**Not Consistent.** The project is not compatible in design and appearance with scenic highway corridors. Riverside County has requested that Interstate 10 (I-10) be designated a State Scenic Highway, but Caltrans has not designated I-10 as either an Eligible or Officially Designated Scenic Highway. Therefore, Riverside County has designated I-10 to be a County Scenic Highway from SR-62 near Palm Springs to the California-Arizona border.
	LU 13.7 Require that the size, height, and type of on-premise signs visible from Designated and Eligible State and County Scenic Highways be the minimum necessary for identification. The design, materials, color, and location of the signs shall blend with the environment, utilizing natural materials where possible.	**Consistent.** The project would include simple identification signage at the facility gate. Such signage would be visible from I-10, a Designated County Scenic Highway.

Applicable LORS	Description	Compliance/Consistency (assumes implementation of staff-recommended conditions of certification)
	LU 13.8 Avoid the blocking of public views by solid walls.	**Consistent.** No solid walls are proposed. However, the high density of project structures would essentially form the appearance of a solid wall of steel and glass that would block views of the surrounding landscape from I-10 and nearby BLM recreational access roads.
The following policies apply to properties designated as Open Space-Rural on the area plan land use maps.	LU 20.1 Require that structures be designed to maintain the environmental character in which they are located. LU 20.2 Require that development be designed to blend with undeveloped natural contours of the site and avoid an unvaried, unnatural, or manufactured appearance. LU 20.4 Ensure that development does not adversely impact the open space and rural character of the surrounding area.	**Not Consistent.** The industrial design and character of the project facilities would not maintain the existing landscape character of a desert valley floor, presently absent such industrial features. **Not Consistent.** The industrial appearance of the project structures and vertical components would not blend with the existing natural-appearing desert valley landscape. **Not Consistent.** Although the project has been intentionally located away from populated areas and sensitive viewers, the project would significantly impact the natural desert landscape and rural character of the site and surroundings.

NOTEWORTHY PUBLIC BENEFITS

While the development of the amended project is intended to address the requirements of federal and state mandates to develop renewable energy, it would not yield any noteworthy public benefits related to visual resources.

RESPONSE TO COMMENTS

STATE OF CALIFORNIA, ENERGY RESOURCES CONSERVATION AND DEVELOPMENT COMMISSION/BASIN AND RANGE WATCH, KEVIN EMMERICH AND LAURA CUNNINGHAM, COMMENTS ON PSA, TN #: 200078, JULY 28, 2013:

Comment: *We would like to see a dark skies KOP simulation of the project. Because the towers would have 16 flashing lights each, this will be a noticeable impact to the night sky.*

Response: The project owner prepared and docketed with the Energy Commission, a study titled *Joshua Tree National Park Visual Resources Analysis Report,* dated May 31, 2013 (Palen 2013v). That study includes three nighttime simulations representing the appearance of the PSEGS at night from three viewpoints within JTNP. Staff did not attempt to validate the accuracy of those simulations, but makes the following observations:

- as indicated in the simulations, at the distances simulated (up to 15 miles), the project would be clearly visible at night.
- in each simulated nighttime view, substantial light from the power block areas is observable, and appears brighter than the solar tower FAA warning lighting. However, Condition of Certification **VIS-3**, which requires shielding of lighting and other mitigation measures, is intended to reduce off-site visibility of power block lighting to a minimum. Lighting conditions similar to those simulated would thus suggest non-compliance with **VIS-3**.
- as illustrated in KOP 3 (South of Eagle Mountain), the broad project setting is not a pristine night sky environment. KOP 3 depicts existing night lighting, apparently of Chuckwalla State Prison, that is a relatively larger and brighter night light source than the proposed project.
- the report also includes analogous night photography of the (under construction) Ivanpah project. However, those photographs include construction lighting and thus appear very bright, compared to what would be expected under PSEGS operation conditions with **VIS-3**. The applicability of those photographs to operational conditions is thus questionable, but they are useful for indicating the considerable brightness of construction activities, even at distances of 15 miles.

Two of the night simulations, KOP 1 and KOP 3, are reproduced at the end of this section as **Visual Resources Figures 10A and 10B, and 11A and 11B.**

Comment: *The impacts that the Palen Project would have on Joshua Tree National Park and wilderness areas surrounding the project can now be compared with the Ivanpah Solar Electric Generating System. The project has now been tested at 10 to 20 percent of full capacity and the glare can be described as intense. It should be blinding at 100 percent. When possible, a full visual analysis of the Ivanpah Project at 100 percent capacity would help us understand the full scope of the visual impacts the Palen towers would have.*

Response: Following publication of the PSEGS PSA, staff conducted field observations of the Ivanpah project during mirror calibration. According to the project owner at that time, one tower (Tower 3) was observed operating at 20 percent capacity, similar to conditions reported by Intervenor Basin and Range Watch. Staff agrees with the commenter that observations of Ivanpah Solar Electric Generating System (ISEGS) at full 100 percent operation would be extremely valuable in evaluating anticipated brightness of PSEGS. As discussed in detail in **APPENDIX TT-1**, clear quantitative criteria for predicting, for example, discomfort levels of glare, are not known. Because no man-made light source of a comparable magnitude of brightness to either the PSEGS or ISEGS solar receivers has ever existed, empirical observations of ISEGS under full operation would provide perhaps the best indication of levels of SRSG brightness impacts, which are in part perceptual and thus partly subjective, experiential effects. Staff understands from the ISEGS project owner, however, that 100 percent operation of ISEGS is unlikely to take place during the time frame of these PSEGS proceedings.

Comment: *Impacts to visual resources could be mitigated with alternate solar technology and preferably, an off –site alternative.*

Response: Staff agrees that visual impacts of PSEGS would be reduced with alternative solar technologies because the most pronounced impact of PSEGS, solar receiver (SRSG) glare, is unique to solar tower technology. This is discussed in the **ALTERNATIVES** section of this FSA.

COUNTY OF RIVERSIDE, JOHN J. BENOIT, COMMENTS ON THE PSA, TN # 200094, JULY 30, 2013:

Comment: The County generally agrees with staff conclusions in the PSA, and notes LORS inconsistencies discussed in the PSA. In addition, the County notes that:

'*Further, the Project is inconsistent with the development standards for any zone in the County's zoning Ordinance No. 348. The two 70-foot tall concrete towers of the Project do not comply with the height limits in any zone in the County. While the Project is not subject to the County's land use ordinance because it is located on BLM land, this inconsistency . . . further demonstrates the visual impact of the project. . . .*

. . . the County does not believe the proposed mitigation is sufficient to off-set the vast changes being imposed on motorists traveling Interstate 10, local residents, and recreational visitors within the vicinity of the Project. Since these impacts cannot be fully mitigated, the residents living in the vicinity should reap some benefit from the Project that they will see and live with daily. . . . The County ask for stronger efforts to minimize and fully mitigate the visual impacts of the Project.'

Response: County's comments are noted. Staff welcomes further discussion of potential visual mitigation that the County proposes.

COLORADO RIVER INDIAN TRIBES, WAYNE PATCH SR., COMMENTS ON THE PSA, TN # 200075, JULY 29, 2013:

Comment: *'CRIT Objects to the Selection of the Key Observation Points in the Visual Resources Section.'*

'The Visual Resources section of the PSA does not address the potential cultural implications of the Project's disruption of the visual landscape on Tribal members.' The CRIT goes on to comment on cultural and spiritual significance of Coxcomb, Chuckwall and McCoy Mountains.

‘CRIT Objects to the PSA’s Absence of Analysis of the Visual Impacts to Traditional Trails.’

‘The analysis of the Project’s impacts to the ‘Prehistoric Trails Network Cultural Landscape’ (PTNCL) does not address the cultural implications of the Project’s disruption of the visual landscape.

Response: Staff acknowledges the absence of discussion on visual effects to the cultural landscape within the Visual Resources analysis. This omission is typically the case in CEQA analyses of visual impacts because, according to staff’s understanding, the applicable criteria for determining significant visual effects on cultural resources, e.g. under Section 106 and corresponding state law, differ from the methodology being used for the visual analysis. Because the expertise needed to evaluate the applicable cultural criteria is outside of the visual resource area, this analysis is typically deferred to cultural resource experts. However, staff is cognizant of the potential for such issues and has strived to provide visual analysis relevant to the purpose of cultural review. Thus, for example, the analysis of KOPs in the Coxcomb, Chuckwalla, and McCoy Mountains should provide an understanding of the extent and intensity of possible *visual* effects in those areas. The selection of KOPs in the visual analysis provides a representative sample of *all* sections of the project viewshed, and thus an understanding of specifically visual effects throughout the viewshed. The evaluation of these visual effects on *cultural* resources and values, including effects on traditional trails is, however, outside of visual staff’s expertise. The reader is thus referred to the **CULTURAL RESOURCES** section of this FSA for these analyses.

SHAUN GONZALEZ, PUBLIC COMMENT, TN # 200041, JULY 15, 2013

Comment: *The CEC should reject BrightSource’s application for a power tower design at the site, and review other alternatives that are significantly less disruptive, such as photovoltaic solar or solar trough with storage.*

Response: For staff’s comparison of potential visual impacts of various alternative technologies, please refer to the **ALTERNATIVES** section of this FSA.

CONCLUSIONS

Energy Commission staff concludes that the Palen Solar Electric Generating System project would result in a substantial adverse impact to existing scenic resource values as seen from several Key Observation Points in the Chuckwalla Valley and Coxcomb, Granite, Palen and Chuckwalla Mountains, including:

- Both westbound and eastbound Interstate 10;
- State Route 177, to the west and northwest of the project site;
- Joshua Tree National Park to the west and northwest of the project site;
- Palen McCoy Wilderness to the northeast of the project site;
- Chuckwalla Mountains Wilderness to the south of the project site.

Staff concludes that these visual impacts would be significant in terms of three of the four criteria of CEQA Appendix G, (the project would have a substantial adverse effect on scenic vistas, the project would substantially degrade the existing visual character or quality of the site and its surroundings, and the project would create a new source of substantial light or glare that would adversely affect daytime or nighttime views in the area). Also, staff concludes that these visual impacts would be significant in terms of the context and intensity of the effects in general. Specifically, the context of the project is one of a broad open desert valley with panoramic vista views of the surrounding rugged mountain ranges and designated wilderness areas including Palen McCoy (to the northeast) and Chuckwalla (to the south), and Joshua Tree National Park (to the north-northwest). Also to the northwest is the Desert Lily Sanctuary Area of Critical Environmental Concern (ACEC). The Palen Dry Lake and Sand Dunes area immediately north of the project site is a popular desert recreation destination area. To the west of the project site is Desert Center and Alligator Rock ACEC.

The landscape of the project vicinity is generally undeveloped and appears mostly natural in character. The panoramic vista views are largely unobstructed and encompass wide-open desert spaces. The proposed project would introduce a densely developed and geographically extensive industrial feature into a landscape presently absent similar features. Most importantly, the project would introduce prominent glare from the solar receiver steam generators (SRSGs) over a large area. Energy Commission staff also concludes that the project's contribution to significant cumulative visual effects would be cumulatively considerable when combined with the effects of other renewable and development projects along the I-10 corridor, within the Chuckwalla Valley, and within the California Desert Conservation Area as a whole.

Energy Commission staff has concluded that the potentially significant visual impacts cited above could not be mitigated to less than significant levels and would thus result in significant and unavoidable impacts under CEQA.

Also, Energy Commission staff concludes that the project would be inconsistent with several goals and policies of the Riverside County Integrated Plan as follows:

- LU 13.1, requiring preservation and protection of outstanding scenic vistas and visual features for the enjoyment of the traveling public. The project would be a highly visible industrial feature in the panoramic, vista views from the southern ridges of Palen McCoy Wilderness, the northeastern ridges of Chuckwalla Mountains Wilderness, and Joshua Tree National Park (though at slightly greater distance).
- LU 13.3, requiring the design and appearance of new structures within Designated County scenic highway corridors (I-10) to be compatible with the surrounding scenic setting. The project would have an industrial appearance that would not be consistent with the surrounding, natural, undeveloped desert landscape.
- LU 20.1, requiring that structures be designed to maintain the environmental character in which they are located. The project's industrial character would not be consistent with the surrounding, natural, undeveloped desert landscape character.

- LU 20.2, requiring that development be designed to blend with undeveloped natural contours of the site and avoid a manufactured appearance. The project would have an industrial, manufactured appearance.
- LU 20.4, requiring that development does not adversely impact the open space and rural character of the surrounding area. The project would convert an open, undeveloped desert landscape to an intensive industrial use.

As stated, staff concludes that the project would have significant unavoidable adverse impacts in both a direct and cumulative context, impacts that could not be fully mitigated. However, if the Energy Commission approves the amended project, staff recommends that the conditions of certification from the Commission Decision for the originally certified Palen Solar Power Project, as modified herein by staff, be adopted in order to minimize impacts to the greatest feasible extent.

CONDITIONS OF CERTIFICATION

The Energy Commission should adopt the following conditions of certification if it approves the amended project. Staff has proposed modifications to the conditions of certification as shown below. (Note: Deleted text is in ~~strikethrough~~, new text is **<u>bold and underlined</u>**).

Condition of Certification **VIS-4** of the PPSP RSA was included in the RSA in response to BLM requirements for what was originally envisioned as a joint state/federal action. However, measures in that condition that are applicable to the current project have been incorporated in the other measures. Condition VIS-4 was thus deleted as redundant to these other conditions.

SURFACE TREATMENT OF PROJECT STRUCTURES AND BUILDINGS

VIS-1 The project owner shall treat the surfaces of all project structures and buildings visible to the public such that a) their colors minimize visual intrusion and contrast by blending with (matching) the existing characteristic landscape colors; b) their colors and finishes do not create excessive glare; and c) their colors and finishes are consistent with local policies and ordinances. The transmission line conductors shall be non-specular and non-reflective, and the insulators shall be non-reflective and non-refractive.

Following in-field consultation with the Energy Commission/BLM Visual Resources specialist and other representatives as deemed necessary, the project owner shall submit for **<u>Energy Commission</u>** Compliance Project Manager (CPM) review and approval, a specific Surface Treatment Plan that will satisfy these requirements. The treatment plan shall include:

A. A description of the overall rationale for the proposed surface treatment, including the selection of the proposed color(s) and finishes based on the characteristic landscape. Colors will be fielded tested using the actual distances from the KOPs to the proposed structures, using the proposed colors painted on representative surfaces;

B. A list of each major project structure, building, tank, pipe, and wall; the transmission line towers and/or poles; and fencing, specifying the color(s) and finish proposed for each. Colors must be identified by vendor, name, and pantone number; or according to a universal designation system;

C. One set of color brochures or color chips showing each proposed color and finish;

D. A specific schedule for completion of the treatment; and

E. A procedure to ensure proper treatment maintenance for the life of the project.

The project owner shall not specify to the vendors the treatment of any buildings or structures treated during manufacture, or perform the final treatment on any buildings or structures treated in the field, until the project owner receives notification of approval of the treatment plan by the CPM. Subsequent modifications to the treatment plan are prohibited without CPM approval.

Verification: At least 90 days prior to specifying to the vendor the colors and finishes of the first structures or buildings that are surface treated during manufacture, the project owner shall submit the proposed treatment plan to the CPM for review and approval and simultaneously to **the BLM and** Riverside County for review and comment. If the CPM determines that the plan requires revision, the project owner shall provide to the CPM a plan with the specified revision(s) for review and approval by the CPM before any treatment is applied. Any modifications to the treatment plan must be submitted to the CPM for review and approval.

Prior to the start of commercial operation, the project owner shall notify the CPM that surface treatment of all listed structures and buildings has been completed and they are ready for inspection and shall submit to each one set of electronic color photographs from the same key observation points identified in (d) above. The project owner shall provide a status report regarding surface treatment maintenance in the Annual Compliance Report. The report shall specify a): the condition of the surfaces of all structures and buildings at the end of the reporting year; b) maintenance activities that occurred during the reporting year; and c) the schedule of maintenance activities for the next year.

REVEGETATION OF DISTURBED SOIL AREAS

VIS-2 The project owner shall minimize visual disturbances due to construction and revegetate disturbed soil areas to the greatest practical extent, as described in Condition of Certification **BIO-8,** measures 1, 2, 5, and 21. In order to address specifically visual concerns, the required spreading of preserved topsoil shall include reclamation of the area of disturbed soils used for laydown, project construction, and siting of the other ancillary operation and support structures that appear in the visual foreground of I-10.

Verification: Refer to Condition of Certification **BIO-8**.

TEMPORARY AND PERMANENT EXTERIOR LIGHTING

VIS-3 To the extent feasible, consistent with safety and security considerations, the project owner shall design and install all permanent exterior lighting and all temporary construction lighting such that a) lamps and reflectors are not visible from beyond the project site, including any off-site security buffer areas; b) lighting does not cause excessive reflected glare; c) direct lighting does not illuminate the nighttime sky, except for required FAA aircraft safety lighting (which should be an on-demand, audio-visual warning system that is triggered by radar technology); d) illumination of the project and its immediate vicinity is minimized, and e) the plan complies with local policies and ordinances. The project owner shall submit to the CPM for review and approval and simultaneously to the **BLM and** County of Riverside for review and comment a lighting mitigation plan that includes the following:

A. Location and direction of light fixtures shall take the lighting mitigation requirements into account;

B. Lighting design shall consider setbacks of project features from the site boundary to aid in satisfying the lighting mitigation requirements;

C. Lighting shall incorporate fixture hoods/shielding, with light directed downward or toward the area to be illuminated;

D. Light fixtures that are visible from beyond the project boundary shall have cutoff angles that are sufficient to prevent lamps and reflectors from being visible beyond the project boundary, except where necessary for security;

E. All lighting shall be of minimum necessary brightness consistent with operational safety and security; and

F. Lights in high illumination areas not occupied on a continuous basis (such as maintenance platforms) shall have (in addition to hoods) switches, timer switches, or motion detectors so that the lights operate only when the area is occupied.

G. Lighting plan shall demonstrate that plant operational lighting will not be reflected upward or off-site by heliostats in nighttime stow position. Control measures for eliminating such reflections shall be incorporated in the HMPP specified in Condition of Certification TRANS-7.

At least 90 days prior to ordering any permanent exterior lighting or temporary construction lighting, the project owner shall contact the CPM to discuss the documentation required in the lighting mitigation plan. At least 60 days prior to ordering any permanent exterior lighting, the project owner shall submit to the CPM for review and approval and simultaneously to the **BLM and** County of Riverside for review and comment a lighting mitigation plan. If the CPM determines that the plan requires revision, the project owner shall provide to the CPM a revised plan for review and approval by the CPM.

The project owner shall not order any exterior lighting until receiving CPM approval of the lighting mitigation plan.

Prior to commercial operation, the project owner shall notify the CPM that the lighting has been completed and is ready for inspection. If after inspection, the CPM notifies the project owner that modifications to the lighting are needed, within 30 days of receiving that notification the project owner shall implement the modifications and notify the CPM that the modifications have been completed and are ready for inspection.

Within 48 hours of receiving a lighting complaint, the project owner shall provide the CPM with a complaint resolution form report as specified in the Compliance General Conditions including a proposal to resolve the complaint, and a schedule for implementation. The project owner shall notify the CPM within 48 hours after completing implementation of the proposal. A copy of the complaint resolution form report shall be submitted to the CPM within 30 days.

PROJECT DESIGN

~~**VIS-4**~~ ~~To the extent possible, the project owner shall use proper design fundamentals to reduce the visual contrast to the characteristic landscape. These include proper siting and location; reduction of visibility; repetition of form, line, color (see VIS-1) and texture of the landscape; and reduction of unnecessary disturbance. Design strategies to address these fundamentals shall be based on the following factors:~~

~~**Earthwork:** Select locations and alignments that fit into the landforms to minimize the size of cuts and fills. Avoid hauling in or hauling out of excess earth cut or fill. Avoid rounding and/or warping slopes. Retain existing rock formations, vegetation, and drainage. Tone down freshly broken rock faces with emulsions or stains. Use retaining walls to reduce the amount and extent of earthwork. Retain existing vegetation by using retaining walls or fill slopes, reducing surface disturbance, and protecting roots from damage during excavations. Avoid soil types that generate strong color contrasts. Reduce dumping or sloughing of excess earth and rock on downhill slopes.~~

~~**Vegetation Manipulation:** Retain as much of the existing vegetation as possible. Use existing vegetation to screen the development from public viewing. Use scalloped, irregular cleared edges to reduce line contrast. Use irregular clearing shapes to reduce form contrast. Feather and thin the edges of cleared areas and retain a representative mix of plant species and sizes.~~

~~**Structures:** Minimize the number of structures and combine different activities in one structure. Use natural, self-weathering materials and chemical treatments on surfaces to reduce color contrast. Bury all or part of the structure. Use natural appearing forms to complement the characteristic landscape. Screen the structure from view by using natural land forms and vegetation. Reduce the line contrast created by straight edges.~~

~~**Linear Alignments:** Use existing topography to hide induced changes associated with roads, lines, and other linear features. Select alignments that follow landscape contours. Avoid fall-line cuts and bisecting ridge tops. Hug vegetation lines and avoid open areas such as valley bottoms. Cross highway corridors and less sharp angles.~~

~~**Reclamation and Restoration:** Reduce the amount of disturbed area and blend the disturbed areas into the characteristic landscape. Replace soil, brush, rocks, and natural debris over disturbed area. Newly introduce plant species should be of a form, color, and texture that blends with the landscape.~~

~~As early as possible in the site and facility design, the project owner shall meet with the CPM to discuss incorporation of these above factors into the design plans. At least 90 days prior to final site and facility design, the project owner shall contact the CPM to review the incorporation of the above factors into the final facility and site design plans. If the CPM determine that the site and facility plans require revision, the project owner shall provide to the CPM a revised plan for review and approval by the CPM.~~

VISUAL RESOURCES APPENDIX VR-1

ENERGY COMMISSION VISUAL RESOURCE ANALYSIS EVALUATION CRITERIA

Energy Commission staff conducts a visual resource analysis according to Appendix G, "Environmental Checklist Form—Aesthetics," California Environmental Quality Act (CEQA). The CEQA analysis requires that commission staff make a determination of impact ranging from "Adverse and Significant" to "Not Significant."

Staff's analysis is based on Key Observation Points or KOPs. KOPs are photographs of locations within the project area that are highly visible to the public—for example, travel routes; recreational and residential areas; and bodies of water as well as other scenic and historic resources.

Those photographs are taken to indicate existing conditions without the project and then modified to include a simulation of the project. Consequently, staff has a visual representation of the viewshed before and after a project is introduced and makes its analysis accordingly. Information about that analytical process follows.

VISUAL RESOURCE ANALYSIS WITHOUT PROJECT

When analyzing KOPs of existing conditions without the project, staff considers the following conditions: visual quality, viewer concern, visibility, number of viewers, duration of view. Those conditions are then factored into an overall rating of viewer exposure and viewer sensitivity. Information about each condition and rating follows.

Visual Quality

An expression of the visual impression or appeal of a given landscape and the associated public value attributed to the resource. Visual quality is rated from *high* to *low*. A high rating is generally reserved for landscapes viewers might describe as picture-perfect.

Landscapes rated high generally are memorable because of the way the components combine in a visual pattern. In addition, those landscapes are free from encroaching elements, thus retaining their visual integrity. Finally, landscapes with high visual quality are visually coherent and harmonious when each element is considered as part of the whole. On the contrary, landscapes rated *low* are often dominated by visually discordant human alterations.

Viewer Concern

Viewer concern represents the reaction of a viewer to visible changes in the viewshed an area of land visible from a fixed vantage point. For example, viewers have a high expectation for views formally designated as a scenic area or travel corridor as well as for recreational and residential areas. Viewers generally expect that those views would be preserved. Travelers on highways and roads, including those in agricultural areas, are generally considered to have moderate viewer concerns and expectations.

However, viewers tend to have low-to-moderate viewer concern when viewing commercial buildings. And industrial uses typically have the lowest viewer concern. Regardless, the level of concern could be lower if the existing landscape contains discordant elements. In addition, some areas of lower visual quality and degraded visual character may contain particular views of substantially higher visual quality or interest to the public.

Visibility

Visibility is a measure of how well an object can be seen. Visibility depends on the angle or direction of views; extent of visual screening; and topographical relationships between the object and existing homes, streets, or parks. In that sense, visibility is determined by considering any and all obstructions that may be in the sightline—trees and other vegetation; buildings; transmission poles or towers; general air quality conditions such as haze; and general weather conditions such as fog.

Number of Viewers

Number of viewers is a measure of the number of viewers per day who would have a view of the proposed project. *Number of viewers* is organized into the following categories: residential according to the number of residences; motorist according to the number of vehicles; and recreationists.

Duration of View

Duration of view is the amount of time to view the site. For example, a high or extended view of a project site is one reached across a distance in two minutes or longer. In contrast, a low or brief duration of view is reached in a short amount of time—generally less than ten seconds.

Viewer Exposure

Viewer exposure is a function of three elements previously listed, *visibility*, *number of viewers*, and *duration of view*. Viewer exposure can range from a *low* to *high*. A partially obscured and brief background view for a few motorists represents a low value; and unobstructed foreground view from a large number of residences represents a high value.

Visual Sensitivity

Visual sensitivity is comprised of three elements previous listed, *visual quality*, *viewer concern*, and *viewer exposure*. Viewer sensitivity tends to be higher for homeowners or people driving for pleasure or engaged in recreational activities and lower for people driving to and from work or as part of their work.

Visual Resource Analysis with Project

Visual resource analyses with photographic simulations of the project involve the elements of contrast, dominance, view disruption, and visual change. Information about each element follows.

Contrast

Contrast concerns the degree to which a project's visual characteristics or elements — form, line, color, and texture — differ from the same visual elements in the existing landscape. The degree of contrast can range from *low* to *high*. A landscape with forms, lines, colors, and textures similar to those of a proposed energy facility is more visually absorbent; that is, more capable of accepting those characteristics than a landscape in which those elements are absent. Generally, visual absorption is inversely proportional to visual contrast.

Dominance

Dominance is a measure of (a) the proportion of the total field of view occupied by the field; (b) a feature's apparent size relative to other visible landscape features; and (c) the conspicuousness of the feature due to its location in the view.

A feature's level of dominance is lower in a panoramic setting than in an enclosed setting with a focus on the feature itself. A feature's level of dominance is higher if it is (1) near the center of the view; (2) elevated relative to the viewer; or (3) has the sky as a backdrop. As the distance between a viewer and a feature increases, its apparent size decreases; and consequently, its dominance decreases. The level of dominance ranges from *low* to *high*.

View Disruption

The extent to which any previously visible landscape features are blocked from view constitutes view disruption. The view is also disrupted when the continuity of the view is interrupted. When considering a project's features, higher quality landscape features can be disrupted by lower quality project features, thus resulting in adverse visual impacts. The degree of view disruption can range from *none* too *high*.

Visual Change

Visual change is a function of *contrast*, *dominance*, and *view disruption*. Generally, *contrast* and *dominance* contribute more to the degree of visual change than does *view disruption*.

WASTE MANAGEMENT

Testimony of Christopher Dennis, PG

SUMMARY OF CONCLUSIONS

The proposed amended project would employ the BrightSource power tower technology, which would eliminate parabolic trough technology and the need for heat transfer fluid (HTF). With the elimination of HTF and the waste management requirements related to this fluid, Condition of Certification **WASTE-8** is no longer required.

Management of the nonhazardous and hazardous waste generated during construction, operation, and closure of the Palen Solar Electric Generating Station (PSEGS) would not result in significant adverse impacts under the California Environmental Quality Act (CEQA) guidelines (Appendix G: Environmental Checklist Section XVI - Utilities and Service Systems). The PSEGS would be consistent with the applicable waste management laws, ordinances, regulations, and standards (LORS), provided that the measures proposed by the applicant and mitigation proposed by Energy Commission staff (staff) are implemented.

INTRODUCTION

This section presents an analysis of the potential adverse environmental impacts and LORS compliance related to the wastes that would be generated by PSEGS during construction, operation, and eventual closure. Management and discharge of wastewater is addressed in the **SOIL AND WATER RESOURCES** section of this document. Additional information related to waste management may also be covered in the **WORKER SAFETY** and **HAZARDOUS MATERIALS MANAGEMENT** sections of this document.

The objectives of this analysis are to evaluate whether:

1. PSEGS generated wastes would be managed in compliance with all applicable LORS;

2. To ensure that wastes generated during PSEGS construction, operation, and closure would be managed and disposed of in an environmentally safe manner and would not significantly and adversely impact existing waste disposal facilities; and

3. To ensure that PSEGS generated wastes and waste constituents would not pose a significant risk to humans or the environment.

METHODOLOGY AND THRESHOLDS FOR DETERMINING ENVIRONMENTAL CONSEQUENCES

Staff analyzed the expected direct, indirect, and cumulative impacts that would be caused by management of waste generated during construction, operation, and closure of PSEGS. This analysis includes evaluation of the potential impact of existing contamination associated with on site activities on or near the PSEGS site and impacts from the generation and management of wastes during demolition of existing structures and during project construction and operation. If potential impacts related to the proposed project would be negative and significant, staff has recommended mitigation to avoid or reduce the effect of those impacts to a level of less than significant.

Staff's analysis includes review of a Phase I Environmental Site Assessment (ESA) submitted as part of the project application for certification. This ESA was updated as part of this proposed project amendment. A Phase I evaluates existing and potential site contamination. The evaluation is performed by a qualified environmental professional who inquires into past uses and ownership of the property, researches hazardous substance releases and hazardous waste disposal at the site and within a certain distance of the site, and visually inspects the property to observe potential contamination and possible areas of concern. After conducting all necessary file reviews, interviews, and site observations, the environmental professional then provides a report of findings about the environmental conditions at the site.

Because the Phase I ESA does not include sampling or testing, the environmental professional may give an opinion about the potential need for any additional investigation. Additional investigation may be needed, for example, if there were significant gaps in the information available about the site, if an ongoing release is suspected, or to confirm an existing environmental condition. If additional investigation is needed to identify the extent of possible contamination, a Phase II ESA may be required. The Phase II ESA usually includes sampling and testing of potentially contaminated media to verify the extent and concentration of contamination. Based on this information, remediation plans, if necessary, can be developed.

If potential or existing releases or contamination is identified, the CEQA significance of the release or contamination is to be determined by site-specific factors, which include:

- The amount and concentration of contaminants or contamination;
- The proposed use of the area where the contaminants/contamination is found; and
- Any potential contaminant exposure pathways to workers, the public or sensitive species or environmental areas.

Unmitigated contamination or releases of hazardous substances that pose a risk to human health or environmental receptors are considered a significant adverse impact.

Staff also analyzed project compliance with the local, state, and federal LORS. LORS compliance is a major component of the determination regarding the significance and acceptability of the proposed project with respect to management of waste.

LAWS, ORDINANCES, REGULATIONS, AND STANDARDS

The following federal, state, and local LORS have been established to ensure the safe and proper management of both non-hazardous and hazardous wastes. These LORS are designed to protect human health and the environment.

Waste Management Table 1
Laws, Ordinances, Regulations, and Standards (LORS)

Applicable LORs	Description
Federal	
Title 42, United States Code (U.S.C.), §6901, et seq. Solid Waste Disposal Act of 1965 (as amended and revised by the Resource Conservation and Recovery Act of 1976, et al.)	The Solid Waste Disposal Act, as amended and revised by the Resource Conservation and Recovery Act (RCRA) et al., establishes requirements for the management of solid wastes (including hazardous wastes), landfills, underground storage tanks, and certain medical wastes. The statute also addresses program administration, implementation and delegation to states, enforcement provisions, and responsibilities, as well as research, training, and grant funding provisions. RCRA Subtitle C establishes provisions for the generation, storage, treatment, and disposal of hazardous waste, including requirements addressing: • Generator record keeping practices that identify quantities of hazardous wastes generated and their disposition; • Waste labeling practices and use of appropriate containers; • Use of a manifest when transporting wastes; • Submission of periodic reports to the United States Environmental Protection Agency (U.S. EPA) or other authorized agency; and • Corrective action to remediate releases of hazardous waste and contamination associated with RCRA-regulated facilities. RCRA Subtitle D establishes provisions for the design and operation of solid waste landfills. RCRA is administered at the federal level by U.S. EPA and its 10 regional offices. The Pacific Southwest regional office (Region 9) implements U.S. EPA programs in California, Nevada, Arizona, and Hawaii.
Title 42, U.S.C., §9601, et seq. Comprehensive Environmental Response, Compensation and Liability Act	The Comprehensive Environmental Response, Compensation and Liability Act (CERCLA), also known as *Superfund*, establishes authority and funding mechanisms for cleanup of uncontrolled or abandoned hazardous waste sites, as well as cleanup of accidents, spills, or emergency releases of pollutants and contaminants into the environment. Among other things, the statute addresses: • Reporting requirements for releases of hazardous substances; • Requirements for remedial action at closed or abandoned hazardous waste sites, and brownfields; • Liability of persons responsible for releases of hazardous substances or waste; and • Requirements for property owners/potential buyers to conduct “all appropriate inquiries” into previous ownership and uses of the property to 1) determine if hazardous substances have been or may have been released at the site, and 2) establish that the owner/buyer did not cause or contribute to the release. A Phase I Environmental Site Assessment is commonly used to satisfy CERCLA “all appropriate inquiries” requirements.
Title 40, Code of	These regulations were established by U.S. EPA to implement the provisions of

Applicable LORs	Description
Federal Regulations (C.F.R.), Subchapter I – Solid Wastes	the Solid Waste Disposal Act and RCRA (described above). Among other things, the regulations establish the criteria for classification of solid waste disposal facilities (landfills), hazardous waste characteristic criteria and regulatory thresholds, hazardous waste generator requirements, and requirements for management of used oil and universal wastes. • Part 257 addresses the criteria for classification of solid waste disposal facilities and practices. • Part 258 addresses the criteria for municipal solid waste landfills. • Parts 260 through 279 address management of hazardous wastes, used oil, and universal wastes (i.e., batteries, mercury-containing equipment, and lamps). U.S. EPA implements the regulations at the federal level. However, California is a RCRA-authorized state, so most of the solid and hazardous waste regulations are implemented by state agencies and authorized local agencies in lieu of U.S. EPA.
Title 49, C.F.R., Parts 172 and 173. Hazardous Materials Regulations	These regulations address the United States Department of Transportation (DOT) established standards for transport of hazardous materials and hazardous wastes. The standards include requirements for labeling, packaging, and shipping of hazardous materials and hazardous wastes, as well as training requirements for personnel completing shipping papers and manifests. Section 172.205 specifically addresses use and preparation of hazardous waste manifests in accordance with Title 40, CFR, section 262.20.
Federal Clean Water Act, 33 U.S.C. §1251 et seq.	The Clean Water Act controls discharge of wastewater to the surface waters of the U.S.
State	
California Health and Safety Code (Health and Safety Code), Chapter 6.5, §25100, et seq. Hazardous Waste Control Act of 1972, as amended	This California law creates the framework under which hazardous wastes must be managed in California. The law provides for the development of a state hazardous waste program that administers and implements the provisions of the federal RCRA program. It also provides for the designation of California-only hazardous wastes and development of standards (regulations) that are equal to or, in some cases, more stringent than federal requirements. The California Environmental Protection Agency (Cal/EPA), Department of Toxic Substances Control (DTSC) administers and implements the provisions of the law at the state level. Certified Unified Program Agencies (CUPAs) implement some elements of the law at the local level.
Title 22, California Code of Regulations (Cal. Code Regs.), Division 4.5. Environmental Health Standards for the Management of Hazardous Waste	These regulations establish requirements for the management and disposal of hazardous waste in accordance with the provisions of the California Hazardous Waste Control Act and federal RCRA. As with the federal requirements, waste generators must determine if their wastes are hazardous according to specified characteristics or lists of wastes. Hazardous waste generators must obtain identification numbers; prepare manifests before transporting the waste off site; and use only permitted treatment, storage, and disposal facilities. Generator standards also include requirements for record keeping, reporting, packaging, and labeling. Additionally, while not a federal requirement, California requires that hazardous waste be transported by registered hazardous waste transporters. The standards addressed by Title 22, CAL. CODE REGS. include: • Identification and Listing of Hazardous Waste (Chapter 11, §66261.1, et seq.). • Standards Applicable to Generator of Hazardous Waste (Chapter 12, §66262.10, et seq.).

Applicable LORs	Description
	• Standards Applicable to Transporters of Hazardous Waste (Chapter 13, §66263.10, et seq.). • Standards for Universal Waste Management (Chapter 23, §66273.1, et seq.). • Standards for the Management of Used Oil (Chapter 29, §66279.1, et seq.). • Requirements for Units and Facilities Deemed to Have a Permit by Rule (Chapter 45, §67450.1, et seq.). The Title 22 regulations are established and enforced at the state level by DTSC. Some generator and waste treatment standards are also enforced at the local level by CUPAs.
Health and Safety Code, Chapter 6.11 §§25404 – 25404.9 Unified Hazardous Waste and Hazardous Materials Management Regulatory Program (Unified Program)	The Unified Program consolidates, coordinates, and makes consistent the administrative requirements, permits, inspections, and enforcement activities of the six environmental and emergency response programs listed below. • Aboveground Petroleum Storage Act requirements for Spill Prevention, Control, and Countermeasure (SPCC) Plans. • Hazardous Materials Release and Response Plans and Inventories (Business Plans). • California Accidental Release Prevention (CalARP) Program. • Hazardous Materials Management Plan / Hazardous Materials Inventory Statements. • Hazardous Waste Generator / Tiered Permitting Program. • Underground Storage Tank Program. The state agencies responsible for these programs set the standards for their programs while local governments implement the standards. The local agencies implementing the Unified Program are known as CUPAs. The DTSC's Calexico Field Office is the CUPA for the SES Solar Two project. Note: The Waste Management analysis only considers application of the Hazardous Waste Generator/Tiered Permitting element of the Unified Program.
Title 27, Cal. Code Regs., Division 1, Subdivision 4, Chapter 1, §15100, et seq. Unified Hazardous Waste and Hazardous Materials Management Regulatory Program	While these regulations primarily address certification and implementation of the program by the local CUPAs, the regulations do contain specific reporting requirements for businesses. • Article 9 – Unified Program Standardized Forms and Formats (§§ 15400–15410). • Article 10 – Business Reporting to CUPAs (§§15600–15620).

Applicable LORs	Description
Public Resources Code, Division 30, §40000, et seq. California Integrated Waste Management Act of 1989 (AB 939)	The California Integrated Waste Management Act (CIWMA) (AB 939) sets mandates and standards for management of solid waste in California for local jurisdictions (cities and counties) and the state. AB 939 sets landfill diversion requirements; a preferred waste management hierarchy (source reduction first, then recycling and reuse, and treatment and disposal last); standards for design and construction of municipal landfills; and programs for county waste management plans and local implementation of solid waste requirements. AB 939 is designed to reduce the volume and toxicity of solid waste landfilled and incinerated by requiring local governments to prepare and implement plans to improve the management of waste resources. AB 939 set out the requirement to reduce the amount of solid waste disposed in landfills and transformed by 50 percent by the year 2000 and every year thereafter, through source reduction, recycling, and composting.
Title 14, Cal. Code Regs., Division 7, §17200, et seq. California Integrated Waste Management Board	These regulations implement the provisions of the California Integrated Waste Management Act and set forth minimum standards for solid waste handling and disposal. The regulations include standards for solid waste management, as well as enforcement and program administration provisions. • Chapter 3 – Minimum Standards for Solid Waste Handling and Disposal. • Chapter 3.5 – Standards for Handling and Disposal of Asbestos Containing Waste. • Chapter 7 – Special Waste Standards. • Chapter 8 – Used Oil Recycling Program. • Chapter 8.2 – Electronic Waste Recovery and Recycling.
Health and Safety Code, Division 20, Chapter 6.5, Article 11.9, §25244.12, et seq. Hazardous Waste Source Reduction and Management Review Act of 1989	This law was enacted to expand the state's hazardous waste source reduction activities. Among other things, it establishes hazardous waste source reduction review, planning, and reporting requirements for businesses that routinely generate more than 12,000 kilograms (approximately 26,400 pounds) of hazardous waste in a designated reporting year. The review and planning elements are required to be done on a four-year cycle, with a summary progress report due to DTSC every fourth year.
Title 22, Cal. Code Regs., §67100.1 et seq. Hazardous Waste Source Reduction and Management Review	These regulations further clarify and implement the provisions of the Hazardous Waste Source Reduction and Management Review Act of 1989 (noted above). The regulations establish the specific review elements and reporting requirements to be completed by generators subject to the act.
Title 23, Cal. Code Regs., Division 3, Chapters 16 and 18	These regulations relate to hazardous material storage and petroleum UST cleanup, as well as hazardous waste generator permitting, handling, and storage. The DTSC Imperial County CUPA is responsible for local enforcement.
Local	
County of Riverside General Plan, Safety Element: Policy S 6.1	Describes the County's policies and siting criteria identified in the County of Riverside Hazardous Waste Management Plan including coordination of hazardous waste facility responsibilities on a regional basis through the Southern California Hazardous Waste Management Authority

Applicable LORs	Description
Riverside County Integrated Waste Management Program	The Countywide Integrated Waste Management Plan (CIWMP) was prepared in accordance with the California Integrated Waste Management Act of 1989, Chapter 1095 (AB 939) to ensure the County's compliance with the requirements of AB 939.
Riverside County Code Title 8 Chapters 8.60, 8.84, and 8.132, Health and Safety	Establishes requirements for the use, generation, storage, and disposal of hazardous and non-hazardous materials and wastes within the County.

PROPOSED MODIFIED PROJECT

The PSEGS site encompasses 3,794 acres, located approximately 0.5 miles north of U.S. Interstate Highway 10 (I-10) and approximately 10 miles east of the community of Desert Center in Riverside County, California. The site is located on vacant, undeveloped public land administered by the Bureau of Land Management (BLM). The only existing structure on the PSEGS site is the Southern California Edison's Eagle Mountain-Blythe 161 kV transmission line. This transmission line would be slightly re-routed near the western end of the PSEGS, around the newly constructed Red Bluff Substation. The modified PSEGS project would consist of:

- Two 250 MW units, each with a 750 feet solar power tower and receiver, power block, and dedicated heliostat field;
- A 15-acre common facilities area with an administration/warehouse building and two, two-acre evaporation ponds;
- A 203-acre temporary construction laydown area;
- A re-routed generation transmission line;
- A re-routed redundant telecommunication line along the generation transmission line; and
- A natural gas delivery connection from a new extension of the existing Southern California Gas distribution system to the PSEGS boundary.

The proposed amended project would employ the BrightSource power tower technology and thereby eliminating the need for parabolic trough technology and HTF.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

This waste management analysis addresses the existing project site conditions and the potential for contamination associated with prior activities on or near the project site, and the potential impacts from the generation and management of wastes during project construction, operation, and closure.

EXISTING PROJECT SITE CONDITIONS AND POTENTIAL FOR CONTAMINATION

Historical use of the PSEGS site included General George Patton's Desert Training Camps during World War II. The site is located near Palen Pass, which was the site of some of the largest mock battles in the California-Arizona Maneuver Area. Live-fire training occurred in camps and facilities in the area and conventional, unconventional, and improvised land mines have been detected in addition to unexploded ordinance (UXO). Due to the proximity of the PSEGS site to Palen Pass and the camps, the project owner plans to conduct pre-construction UXO surveys with qualified technicians that meet Department of Defense requirements and/or employ UXO experts during ground disturbances in areas that may contain UXO (AECOM 2010a, DR-WM-279). The project owner also provided an outline for the Munitions and Explosions of Concern/UXO Recognition Training Program (AECOM 2010a). Existing Condition of Certification **WASTE-1** requires UXO training, investigation, removal, and disposal.

A Phase I ESA, dated May 2009, was prepared by AECOM in accordance with the American Society for Testing and Materials (ASTM) Standard Practice E 1527-05 for ESAs (Solar Millennium, 2009a). The 2009 ESA did not identify any Recognized Environmental Conditions (REC) in connection with historical or current site operations. An REC is the presence or likely presence of any hazardous substances or petroleum products on a property under the conditions that indicate an existing release, past release, or a material threat of a release of any hazardous substance or petroleum products into structures on the property, the ground, groundwater, or surface water.

The environmental records review portion of the 2009 ESA was updated on June 10, 2013. No changes in historical or current records were identified in this update (Palen, 2013cc). The ESA update was done in compliance with ASTM E 1527-05, which contains provisions for updating an existing ESA.[1]

In the event that contamination is identified during any phase of construction, existing Condition of Certification **WASTE-2** requires the availability of an experienced and qualified Professional Engineer or Professional Geologist for consultation. If contaminated soil is identified, existing Condition of Certification **WASTE-3** requires that the Professional Engineer or Professional Geologist inspect the site, determine what is required to characterize the nature and extent of contamination, and provide a report to the Energy Commission compliance project manager (CPM) and DTSC with findings and recommended actions. Condition of Certification **WASTE-3** also requires the Phase I to be updated with a current onsite inspection for RECs.

In the unlikely event that contaminated soil is encountered during excavation activities, the soil would be segregated, sampled, and tested to determine appropriate disposal and treatment options. If the soil is classified as hazardous, the Riverside County Department of Environmental Health would be notified and the soil hauled to a Class I landfill or other appropriate soil treatment and recycling facility, as required. The Riverside County Department of Environmental Health would also be notified if previously unknown

[1] These provisions require an ESA to be updated within a year if a new project is proposed for the property on which the initial ESA was prepared.

wells, tanks, or other underground storage facilities are discovered during construction. Subsequent removal of such equipment, including potential remediation activities, would be conducted in accordance with applicable LORS (Solar Millennium, 2009a). Staff believes that existing Conditions of Certification **WASTE-2** and **WASTE-3** would be adequate to address any soil contamination contingency that may be encountered during construction of the project and would further support compliance with LORS.

IMPACTS FROM GENERATION AND MANAGEMENT OF WASTES DURING PROJECT CONSTRUCTION, OPERATION, AND CLOSURE

Handling and management of waste generated by PSEGS would follow the hierarchical approach of source reduction, recycling, treatment, and disposal as specified in California Public Resources Code Sections 40051 and 40196. The first priority of the project owner is to use materials that reduce the waste that is generated. The next level of waste management involves reusing or recycling wastes. For wastes that cannot be recycled, treatment is to be used, if possible, to make the waste nonhazardous. Finally, waste that cannot be reused, recycled, or treated is to be transported off site to a permitted treatment, storage, or disposal facility.

Direct/Indirect Impacts and Mitigation

The Integrated Waste Management Act of 1989 [Assembly Bill (AB) 939, Sher, Chapter 1095, Statutes of 1989] set landfill waste diversion goals for local jurisdictions of 50 percent by the year 2000. To meet this goal, many jurisdictions require applicants for construction and demolition projects to submit a reuse/recycling plan for at least 50 percent of construction and demolition materials prior to the issuance of a building or demolition permit. While Riverside County does not have such a requirement, staff encourages the project owner to meet the 50 percent waste diversion rate.

Construction

Site preparation and construction of PSEGS would last approximately 34 months and generate non-hazardous, universal, and hazardous wastes in solid and liquid forms. Based on estimates by the project owner, these waste streams and volumes generated by the modified project would be roughly the same as those of the original project. Non-hazardous solid wastes generated during PSEGS construction would consist of scrap wood, rock, sand, concrete, metals, glass, plastic, paper, insulating materials, oil filters, sanitary, and food waste. The composition and volume of PSEGS non-hazardous construction waste would not differ significantly from that of the original project. For all construction waste, recyclable materials would be separated and removed to recycling facilities. Non-recyclable materials would be disposed of at a Class III landfill.

Wastewater would be generated during construction, and would include sanitary waste, hydrostatic test water, and equipment wash water. Sanitary waste would be contained in portable facilities and routinely disposed of at an offsite treatment/disposal facility by a sanitary service. Hydrostatic test water would be disposed of in accordance with in State Water Resources Control Board (SWRCB) *Order No. 2003-003-DWQ Statewide General Waste Discharge Requirements (WDRs) for Discharges to Land with a Low Threat to Water Quality (General WDRs)*. Potentially contaminated equipment wash water would be contained at designated wash areas and transported to a wastewater treatment facility via a licensed hauler. Please see the **SOIL AND WATER RESOURCES** section of this document for more information about the management of project wastewater.

Universal waste generated during construction would include spent alkaline batteries and fluorescent and mercury vapor lamps. The spent batteries and lamps would be recycled or disposed of by licensed universal waste handlers. Universal waste would be accumulated for less than one year and recycled off site. Before construction begins, the project owner would be required to develop and implement a Construction Waste Management Plan to ensure that waste is recycled when possible and properly landfilled as necessary. Existing Condition of Certification **WASTE-4** requires the project owner to submit a Construction Waste Management Plan to the CPM at least 30 days prior to the start of construction activities.

Hazardous waste generated during construction would include empty hazardous material containers, solvents, used oil and lube, paint, adhesives, oily rags, oil sorbent, spent welding materials, spent lead-acid batteries, corrosive cleaning materials, and flushing and cleaning wash water. This hazardous construction waste does not differ significantly from that of the original project. Empty hazardous material containers would be returned to the vendor or disposed of at a hazardous waste facility. Spent lead-acid batteries, solvents, used oils and lube, paint, adhesives, oil sorbent, and oily rags would be disposed of at a hazardous waste facility, recycled, or used for energy recovery. Corrosive cleaning materials would be disposed of at a permitted hazardous waste disposal facility. Flushing and cleaning wash water would be recycled, used for energy recovery, or disposed of based on its specific waste stream characteristics.

The generation of hazardous waste requires a unique hazardous waste generator identification number. The hazardous waste generator number is determined based on site location and, therefore, both the construction contractor and the PSEGS project owner/operator could be considered the generator of hazardous wastes at the site. The PSEGS project owner would be required to obtain a unique hazardous waste generator identification number for the site prior to starting construction in compliance with California Code of Regulation Title 22, Division 4.5. Existing Condition of Certification **WASTE-5** would require the PSEGS project owner to submit the notification and issued identification number documentation to the CPM prior to construction activity.

Hazardous wastes would be collected in hazardous waste accumulation containers and stored in a laydown area, warehouse area, or storage tank on equipment skids for less than 90 days (or less than 180 days in the case of lead acid batteries). The accumulated wastes would then be properly manifested, transported, and disposed of at a permitted hazardous waste disposal facility by a licensed hazardous waste collection and disposal firm. Staff reviewed the disposal methods and concluded that all wastes would be disposed of in accordance with all applicable LORS. Should any construction waste management-related enforcement action be taken or initiated by a regulatory agency, the project owner would be required by existing Condition of Certification **WASTE-6** to notify the CPM whenever the owner becomes aware of such action.

Operation

The proposed modified project would generate non-hazardous, universal, and hazardous wastes in solid and liquid forms under normal operating conditions. Based on estimates by the project owner, these waste streams and volumes generated by the modified project would be roughly the same as those of the original project.

PSEGS would generate non-hazardous waste, such as routine maintenance wastes (used air filters, spent deionization resins, sand and filter media) and domestic and office wastes (office paper, newsprint, aluminum cans, plastic, and glass). All non-hazardous solid wastes would be recycled to the maximum extent possible and non-recyclable wastes would be regularly transported off-site to a solid waste disposal facility.

Non-hazardous liquid wastes would be generated during facility operation and would include reverse osmosis (RO) membrane cleaning waste, RO system concentrate, and sanitary wastewater. RO membrane cleaning waste would be adjusted to neutralize its pH and used as a dust suppressant on-site or disposed of at a permitted waste management facility. Sanitary wastewater would be piped to an on-site septic system and leach field. RO system concentrate would be used for dust control if determined to be inert or disposed of at a permitted waste management facility if determined to be designated waste.

Project operations would also generate universal waste, including spent batteries (e.g., alkaline dry cell, nickel-cadmium, or lithium ion) and spent fluorescent bulbs or high-intensity discharge lamps. Universal waste would be accumulated for less than one year and recycled off-site. In accordance with existing Condition of Certification **WASTE-7**, the project owner would be required to develop and implement an Operations Waste Management Plan which would require documentation of the actual operational waste streams and waste volumes. The measures in the Operations Waste Management Plan would ensure that operational wastes are treated in compliance with all LORS and that an accurate record of PSEGS waste generation, storage, and disposal practices is maintained.

Hazardous wastes generated during project operations would include used lubricating oil and oil filters, solvents, paint, adhesives, oily rags, and oil sorbents. Used oils and grease would be recycled. Effluent from the oil-water separation system would be recycled. Oil adsorbent and oil filters would be sent off-site for recovery or disposal at a Class I landfill. No HTF-related wastes would be generated. Therefore, Condition of Certification **WASTE-8** is no longer required.

The PSEGS project owner would be considered the generator of hazardous wastes during facility operations. The hazardous waste generated identification number that would be required before the start of construction would be the same identification number used during project operations as required by existing Condition of Certification **WASTE-5**.

Proper hazardous material handling, good housekeeping practices, and personnel training would help keep spill wastes to a minimum. To ensure proper cleanup and management of any contaminated soils or waste materials generated from hazardous materials spills, existing Condition of Certification **WASTE-9** requires the project operator to document, clean up, and properly manage and dispose of wastes from any hazardous materials spills or releases in accordance with all applicable federal, state, and local requirements. More information related to hazardous materials management is provided in the **HAZARDOUS MATERIALS MANAGEMENT** section of this document.

The hazardous wastes generated during proposed modified project operations would be temporarily stored on-site, transported off-site by licensed hazardous waste haulers, and recycled or disposed of at authorized disposal facilities in accordance with established standards applicable to generators of hazardous waste (Title 22, Cal. Code Regs., §66262.10 et seq.). Should any operations waste management-related enforcement action be taken or initiated by a regulatory agency, the project owner would be required by existing Condition of Certification **WASTE-6** to notify the CPM when advised of any such action.

Closure

The closure of the proposed modified project would produce both hazardous and non-hazardous solid and liquid waste. The project owner did not identify waste streams or quantities of materials requiring disposal from closure. Required elements of a facility's non-operation and closure are outlined in a repair/restoration plan and facility closure plan as specified in proposed Conditions of Certification **COMPLIANCE-14** and **-15**. To ensure adequate review of a planned project closure, the PSEGS project owner would be required to submit a proposed facility closure plan to the CPM for review and approval at least 36 months (or other period of time agreed to by the CPM) prior to commencement of closure activities. The facility closure plan would document non-hazardous and hazardous waste management practices, including the inventory, management, and disposal of hazardous materials and wastes and permanent disposal of permitted hazardous materials and waste storage units. In addition, the plan would identify landfills with adequate capacity to receive closure-generated wastes. Conditions of Certification **WASTE-1** through **WASTE-10,** excluding **WASTE-8**, would apply to the proposed modified project during closure of PSEGS.

IMPACT ON EXISTING WASTE DISPOSAL FACILITIES

The Rio Mesa SEGF project, which proposed to use the same technology with the same capacity and would occupy virtually the same acreage, provided the following construction and operation non-hazardous waste and hazardous waste volume estimates (CEC, 2012):

- Construction non-hazardous waste (2,135 cubic yards) and hazardous waste (153 cubic yards).
- Operation for 30-years non-hazardous waste (2,070 cubic yards) and hazardous waste (2,160 cubic yards).

The PSEGS project owner estimated the operational non-hazardous waste volume would be 335 tons per year (approximately 1,500 cubic yards over 30 years) (Palen, 2013cc). This volume is similar to the estimate of 2,070 cubic yards provided for Rio Mesa SEGF. These volumes of non-hazardous and hazardous waste do not differ significantly from that of the PSEGS original project, except, however, no HTF would be used and no HTF related wastes would be generated.

Non-hazardous waste would be stored on site in appropriate containers and recycled or disposed of in a Class III landfill on a regular basis. As shown in **Waste Management Table 2**, there are six Class III waste disposal facilities in Riverside County that could potentially accommodate the PSEGS non-hazardous construction and operation wastes project: Badlands, Blythe, Desert Center, Lamb Canyon, Mecca II, and Oasis (CalRecycle, 2013).

Waste Management Table 2
Riverside County Landfill Capacity

Landfill	Permitted Days of Operation	Remaining Capacity (cubic yards)
Badlands	Mon - Sat, closed holidays	14,730,025
Blythe	Mon - Fri and first Sat of the month, closed holidays	4,159,388
Desert Center	2 days per year, closed holidays	23,246
Lamb Canyon	Mon - Sat, closed holidays	18,955,000
Mecca II	2 days per year, closed holidays	34,786
Oasis	Every Weds and Sat, closed holidays	149,597
	Total	**38,052,042**

Sources: CalRecycle, 2013; RCoWMD, 2013.

The combined remaining capacity of these six landfills is approximately 38 million cubic yards (CalRecycle, 2013). The non-recyclable, non-reusable component of the PSEGS waste stream would contribute to filling the available capacity of these landfills and would contribute a substantial portion of the remaining capacity at the Desert Center and Mecca II landfills. The remaining capacity of Desert Center and Mecca II landfills is limited to 34,786 cubic yards and 23,246 cubic yards, respectively (CalRecycle, 2013). In addition, the days of operation of these two landfills is very limited (RCoWMD, 2013). Therefore, existing Condition of Certification **WASTE-10** would require that all project-related non-hazardous, non-recyclable, and non-reusable construction and operation waste be diverted to Riverside County landfills other than Desert Center and Mecca II. Disposal of the non-hazardous solid wastes generated by the proposed modified project could occur without impacting the capacity or remaining life of the other Class III facilities.

There are two Class I waste disposal facilities in California that are currently accepting hazardous waste: Clean Harbors Buttonwillow Landfill in Kern County and the Chemical Waste Management Kettleman Hills Landfill in Kings County (Solar Millennium, 2009a). In total, there is a combined excess of 10 million cubic yards of remaining hazardous waste disposal capacity at these landfills with at least 30 remaining operating years (Solar Millennium, 2009a). In addition, the Kettleman Hills facility is in the process of permitting an additional 4.6 to 4.9 million cubic yards of disposal capacity (Waste Management, 2009). Hazardous wastes generated during construction, operation, and closure would be recycled to the extent possible and practical. Those wastes that cannot be recycled would be transported off site to a permitted treatment, storage, or disposal facility.

As noted above, type and quantity of waste for non-operation and closure have not been identified. The repair/restoration plan and facility closure plan prepared pursuant to Conditions of Certification **COMPLIANCE-14** and **-15** would provide this information as well as disposal facilities with adequate capacity to receive the wastes.

Cumulative Impacts

A project may result in a significant adverse cumulative impact where its effects are cumulatively considerable. "Cumulatively considerable" means that the incremental effects of an individual project are significant when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects (California Code of Regulations, Title 14, section 15130). NEPA states that cumulative effects can result from individually minor but collectively significant actions taking place over a period of time" (40 CFR §1508.7).

As proposed, the amount of non-hazardous and hazardous wastes generated during construction and operation of PSEGS would add to the total quantity of waste generated in Riverside County. Project non-hazardous wastes would be generated in modest quantities, approximately 2,135 cubic yards of solid waste during construction and 69 cubic yards per year during operation. These wastes would be recycled wherever practical and sufficient capacity is available at several treatment and disposal facilities to handle the volumes of wastes that would be generated by the project. The four available Class III landfills listed in **Waste Management Table 2** have a remaining capacity of approximately 38 million cubic yards.

Approximately 153 cubic yards of construction hazardous waste and 72 cubic yards per year of operation hazardous waste would be generated by PSEGS. California Class I landfills have over 15 million cubic yards of remaining capacity for hazardous waste. There is sufficient landfill capacity for hazardous waste in Riverside County.

The amount of non-hazardous and hazardous wastes generated during construction, operation, and closure of PSEGS would add to the total quantity of hazardous and non-hazardous waste generated in Riverside County. Projects in Riverside County would recycle waste wherever practical and sufficient landfill capacity is available throughout the area, especially with the addition of the Mesquite Regional Landfill with a capacity of 600 million tons when it is fully constructed (Fisher, 2013). As part of the County of Riverside AB 939 planning and reporting requirements, the county estimates that the existing county waste disposal system provides approximately 59.3 million tons of permitted disposal capacity (as of 12/31/2006), which would provide more than 15 years of the county's disposal capacity (RCoWMD, 2009). Therefore, impacts of PSEGS, when combined with impacts of other development projects currently proposed within Riverside County, would not result in significant adverse cumulative impacts under CEQA. Staff concludes that the waste generated by PSEGS would not cumulatively result in local or regional significant adverse waste management impacts under CEQA, provided that applicant complies with Condition of Certification **WASTE-10** and diverts project wastes to Riverside County landfills with adequate capacity.

LORS COMPLIANCE

Energy Commission staff concludes that the proposed modified project would comply with all applicable LORS regulating the management of non-hazardous and hazardous wastes during facility construction and operation. The project owner would be required to recycle and/or dispose of non-hazardous and hazardous wastes at facilities licensed or otherwise approved to accept the wastes. Because hazardous wastes would be produced during project construction and operation, PSEGS would be required to obtain a hazardous waste generator identification number from U.S. EPA. PSEGS would also be required to:

- Properly store, package, and label all hazardous waste;
- Use only approved transporters;
- Prepare hazardous waste manifests;
- Keep detailed records; and
- Appropriately train employees in accordance with state and federal hazardous waste management requirements.

NOTEWORTHY PUBLIC BENEFITS

PSEGS would not require use of HTF. The elimination of the use of HTF eliminates the possibility of HTF soil contamination and the need for removal of HTF-impacted soil to a Class I hazardous waste landfill or onsite bioremediation to non-hazardous concentrations.

RESPONSE TO COMMENTS

COUNTY OF RIVERSIDE/JOHN J. BENOIT, COMMENTS ON THE PRELIMINARY STAFF ASSESSMENT FOR THE PROPOSED PSEGS, TN # 200094, JULY 30, 2013:

In a comment letter dated July 30, 2013, the County of Riverside had reserved the right to comment on the waste management section of the Preliminary Staff Assessment pending submittal of additional data staff had requested. Staff has subsequently received the information requested. This information included:

- An updated Phase I ESA;
- Estimates of the type and volume of hazardous and non-hazardous waste expected to be generated by construction and operation of the proposed project; and
- An updated summary of the anticipated operation waste streams, estimated waste volumes, and generation frequency and proposed management methods.

During a telephone conversation on August 15, 2013, staff discussed the project owner's submittal of this information with the county (RCoWMD, 2013b). Based on this discussion, the county believes there would be no significant waste management impacts provided the proposed project complies with all LORS, as proposed by staff.

CONCLUSIONS

After review of the project owner’s proposed waste management procedures, staff concludes that:

- In areas that may contain UXO, pre-construction UXO surveys with qualified technicians that meet Department of Defense requirements and/or employ UXO experts during ground disturbances are required;
- In the unlikely event that contaminated soil is encountered during excavation activities, the soil would be segregated, sampled, and tested to determine appropriate disposal and treatment options;
- PSEGS wastes would be managed in compliance with all applicable waste management LORS;
- Construction, operation, and closure wastes would be characterized and managed as either hazardous or non-hazardous waste;
- All non-hazardous wastes would be recycled or reused to the extent feasible, and non-recyclable wastes would be collected by a licensed hauler and disposed of at a permitted solid waste disposal facility; and
- Hazardous wastes would be accumulated on site in accordance with maximum allowable accumulation times, and then properly manifested, transported to, and disposed of at a permitted hazardous waste management facility by licensed hazardous waste collection and disposal companies.

Based on estimates provided by the project owner, disposal of non-hazardous PSEGS wastes would be approximately the same as the original project, and would not adversely impact Class III landfill capacity and disposal of project-related hazardous wastes would not adversely impact Class I landfill capacity.

Existing Conditions of Certification **WASTE-1** through **-7**, **-9** and **-10** would ensure that PSEGS would remain in compliance and no new conditions of certification are proposed. These conditions would require the project owner to:

- Ensure the project site is investigated and remediated for any UXO that may pose a risk to construction personnel or the environment (**WASTE-1**);
- Ensure the project site is investigated and any contamination identified is remediated as necessary, with appropriate professional and regulatory agency oversight (**WASTE-2** and **-3**);
- Obtain approval for the Construction Waste Management and Operation Waste Management Plans detailing the types and volumes of wastes to be generated and how wastes will be managed, recycled, and/or disposed of after generation (**WASTE-4** and **-7**);
- Obtain a hazardous waste generator identification number from the United States Environmental Protection Agency (**WASTE-5**);
- Report any waste management-related LORS enforcement actions and how violations will be corrected (**WASTE-6**);

- Ensure that all spills or releases of hazardous substances are reported and cleaned-up in accordance with all applicable federal, state, and local requirements; (**WASTE-9**); and
- Ensure that non-recyclable solid waste is diverted to landfills with sufficient remaining capacity (**WASTE-10**).

Because the proposed amended project would employ the BrightSource power tower technology, which would eliminate parabolic trough technology and the need for HTF, staff is recommending the deletion of Waste Discharge Requirement stipulations for treatment of HTF-contaminated soils (**WASTE-8**).

PROPOSED CONDITIONS OF CERTIFICATION

Staff has proposed modifications to the **Waste Management** conditions of certification as shown below. (**Note:** Deleted text is in ~~strikethrough~~; new text is **<u>bold and underlined</u>**)

WASTE-1 The project owner shall prepare a UXO Identification, Training and Reporting Plan to properly train all site workers in the recognition, avoidance and reporting of military waste debris and ordnance. The project owner shall submit the plan to the ~~Compliance Project Manager (~~CPM~~)~~ for review and approval prior to the start of construction. The project owner shall provide documentation of the plan and provide survey results to the CPM. The plan shall contain, at a minimum, the following:

- A description of the training program outline and materials, and the qualifications of the trainers;
- Identification of available trained experts who will oversee earth-moving activities where ordnance could be uncovered and respond to notification of discovery of any ordnance (unexploded or not); and
- Work plan to identify, recover, and remove discovered ordnance, and to complete additional field screening, including geophysical surveys to investigate adjacent areas for surface, near surface or buried ordnance in all proposed land disturbance areas.

<u>Verification:</u> The project owner shall submit the UXO Identification, Training and Reporting Plan to the CPM for approval no later than 30 days prior to the start of site mobilization. The results of geophysical surveys shall be submitted to the CPM within 30 days of completion of the surveys.

WASTE-2 The project owner shall provide the résumé of an experienced and qualified Professional Engineer or Professional Geologist to the ~~Compliance Project Manager (~~CPM~~)~~ for review and approval. The résumé shall show experience in remedial investigation and feasibility studies. This Professional Engineer or Professional Geologist shall be available during site characterization (if needed), excavation, grading, and demolition activities. The Professional Engineer or Professional Geologist shall be given authority by the project owner to oversee any earth-moving activities that have the potential to disturb contaminated soil and impact public health, safety, and the environment.

Verification: No later than 30 days prior to the start of site mobilization the project owner shall submit the resume to the CPM for review and approval.

WASTE-3 If potentially contaminated soil is identified during site characterization, excavation, grading, or demolition at either the proposed site or linear facilities—as evidenced by discoloration, odor, detection by handheld instruments, or other signs—the Professional Engineer or Professional Geologist shall inspect the site; determine the need for sampling to confirm the nature and extent of contamination; and provide a written report to the project owner, representatives of Department of Toxic Substances Control (DTSC) or Regional Water Quality Control Board (RWQCB) and the ~~Compliance Project Manager (~~CPM~~)~~ stating the recommended course of action.

Depending on the nature and extent of contamination, the Professional Engineer or Professional Geologist shall have the authority to temporarily suspend construction activity at that location for the protection of workers or the public. If in the opinion of the Professional Engineer or Professional Geologist significant remediation may be required, the project owner shall contact the CPM and representatives of the DTSC or RWQCB for guidance and possible oversight.

Verification: The project owner shall submit any reports filed by the Professional Engineer or Professional Geologist to the CPM within 5 days of their receipt. The project owner shall notify the CPM within 24 hours of any orders issued to halt construction.

WASTE-4 The project owner shall submit a Construction Waste Management Plan to the ~~Compliance Project Manager (~~CPM~~)~~ for review and approval prior to the start of construction. The plan shall contain, at a minimum, the following:

- a description of all construction waste streams, including projections of frequency, amounts generated and hazard classifications;
- a survey of structures to be demolished that identifies the types of waste to be managed;
- a reuse/recycling plan for construction and demolition materials that meets or exceeds the 50 percent waste diversion goal established by the Integrated Waste Management Compliance Act; and,
- management methods to be used for each waste stream, including temporary on-site storage, housekeeping and best management practices to be employed, treatment methods, and companies providing treatment services, waste testing methods to assure correct classification, methods of transportation, disposal requirements and sites, and recycling and waste minimization/reduction plans.

Verification: The project owner shall submit the Construction Waste Management Plan to the CPM for approval no later than 30 days prior to the initiation of construction activities at the site.

WASTE-5 The project owner shall obtain a hazardous waste generator identification number from the United States Environmental Protection Agency (USEPA) prior to generating any hazardous waste during project construction and operations.

Verification: The project owner shall keep a copy of the identification number on file at the project site and provide documentation of the hazardous waste generation and notification and receipt of the number to the CPM in the next scheduled monthly compliance report after receipt of the number. Submittal of the notification and issued number documentation to the CPM is only needed once unless there is a change in ownership, operation, waste generation, or waste characteristics that requires a new notification to USEPA. Documentation of any new or revised hazardous waste generation notifications or changes in identification number shall be provided to the CPM in the next scheduled compliance report.

WASTE-6 Upon notification of any impending waste management-related enforcement action related to project site activities by any local, state, or federal authority, the project owner shall notify the CPM of any such action taken or proposed against the project itself, or against any waste hauler or disposal facility or treatment operator with which the owner contracts for the project, and describe the owner's response to the impending action or if a violation has been found, how the violation will be corrected.

Verification: The project owner shall notify the CPM in writing within 10 days of receiving written notice from authorities of an impending enforcement action. The CPM shall notify the project owner of any changes that will be required in the way project-related wastes are managed as a result of a finalized action against the project.

WASTE-7 The project owner shall submit the Operation Waste Management Plan to the CPM for review and approval. The plan shall contain, at a minimum, the following:

- a detailed description of all operation and maintenance waste streams, including projections of amounts to be generated, frequency of generation, and waste hazard classifications;
- management methods to be used for each waste stream, including temporary on-site storage, housekeeping and best management practices to be employed, treatment methods and companies providing treatment services, waste testing methods to ensure correct classification, methods of transportation, disposal requirements and sites, and recycling and waste minimization/source reduction plans;
- information and summary records of contacts with the local Certified Unified Program Agency and the ~~Department of Toxic Substances Control~~ **DTSC** regarding any waste management requirements necessary for project activities. Copies of all required waste management permits, notices, and/or authorizations shall be included in the plan and updated as necessary;

- a detailed description of how facility wastes will be managed and any contingency plans to be employed, in the event of an unplanned closure or planned temporary facility closure; and
- a detailed description of how facility wastes will be managed and disposed upon closure of the facility.

Verification: The project owner shall submit the Operation Waste Management Plan to the CPM for approval no later than 30 days prior to the start of project operation. The project owner shall submit any required revisions to the CPM within 20 days of notification from the CPM that revisions are necessary.

The project owner shall also document in each annual compliance report the actual volume of wastes generated and the waste management methods used during the year, provide a comparison of the actual waste generation and management methods used to those proposed in the original Operation Waste Management Plan, and update the Operation Waste Management Plan as necessary to address current waste generation and management practices.

~~**WASTE-8** The project owner shall document all releases and spills of Heat Transfer Fluid (HTF) as described in Condition **WASTE-9** and report only those that are 42 gallons or more, the CERCLA reportable quantity, as required in the **SOIL AND WATER RESOURCES** section of this Decision. Cleanup and temporary staging of HTF-contaminated soils shall be conducted in accordance with the approved Operation Waste Management Plan required in Condition **WASTE-7**. The project owner shall sample HTF-contaminated soil from CERCLA reportable incidents involving 42 gallons or more in accordance with the United States Environmental Protection Agency's (USEPA) current version of "Test Methods for Evaluating Solid Waste" (SW-846). Samples shall be analyzed in accordance with USEPA Method 8015 or other method to be reviewed and approved by DTSC and the CPM.~~

~~Within 28 days of an HTF spill, the project owner shall provide the results of the analyses and their assessment of whether the HTF-contaminated soil is considered hazardous or non-hazardous to the Department of Toxic Substances Control (DTSC) and the CPM for review and approval.~~

~~If DTSC, and the CPM determine the HTF-contaminated soil is considered hazardous, it shall be disposed of in accordance with California Health and Safety Code Section 25203 and procedures outlined in the approved Operation Waste Management Plan required in Condition **WASTE-7** and reported to the CPM in accordance with Condition **WASTE-9**.~~

~~If DTSC and the CPM determine the HTF-contaminated soil is considered non-hazardous it shall be retained in the land treatment unit (LTU) and treated on-site in accordance with the Waste Discharge Requirements contained in the **SOIL AND WATER RESOURCES** section of this Decision.~~

~~**Verification:** The project owner shall submit to the CPM and the DTSC for approval the project owner's assessment of whether the HTF contaminated soil is considered hazardous or non-hazardous under state regulations. HTF-contaminated soil that exceeds the regulatory hazardous waste levels must be disposed of in accordance with California Health and Safety Code Section 25203. HTF-contaminated soil that does not exceed the hazardous waste levels may be discharged to the on-site LTU. For discharges into the LTU, the project owner shall comply with the Waste Discharge Requirements contained in the **SOIL AND WATER RESOURCES** section of this Decision.~~

WASTE-9 The project owner shall ensure that all accidental spills or unauthorized releases of hazardous substances, hazardous materials, and hazardous waste are documented and remediated, and that wastes generated from accidental spills and unauthorized releases are properly managed and disposed of in accordance with all applicable federal, state, and local LORS and requirements. For the purpose of this condition of certification, "release" shall have the definition in Title 40 of the Code of Federal Regulations, Part 302.3.

Verification: No later than 30 days of the date that a project-related hazardous substance release was discovered, the project manager shall provide a copy of the accidental spill or unauthorized release documentation to the CPM.

The project owner shall document management of all accidental spills and unauthorized releases of hazardous substances, hazardous materials, and hazardous wastes that occur on the project property or related linear facilities. The documentation shall include, at a minimum, the following information: location of release; date and time of release; reason for release; volume released; how release was managed and material cleaned up; amount of contaminated soil and/or cleanup wastes generated; if the release was reported; to whom the release was reported; release corrective action and cleanup requirements placed by regulating agencies; level of cleanup achieved and actions taken to prevent a similar release or spill; and disposition of any hazardous wastes and/or contaminated soils and materials that may have been generated by the release.

WASTE-10 The project owner shall ensure that none of the project's non-hazardous, non-recyclable, and non-reusable construction and operation wastes shall be diverted to or deposited at either the Desert Center Landfill or the Oasis Sanitary Landfill.

Verification: The project owner shall provide documentation of all project-related solid waste disposal activities and identify the landfills receiving project-related wastes in the annual compliance report submitted to the CPM.

WORKER SAFETY AND FIRE PROTECTION

Testimony of Alvin Greenberg, Ph.D.

SUMMARY OF CONCLUSIONS

California Energy Commission (Energy Commission) staff (staff) concludes that if the project owner for the proposed modified Palen Solar Electric Generating System (PSEGS) provides a Project Construction Safety and Health Program and a Project Operations and Maintenance Safety and Health Program, as required by revised Conditions of Certification **WORKER SAFETY-1**and **-2** and fulfills the requirements of Conditions of Certification **WORKER SAFETY-3** through **-12**, the project would incorporate sufficient measures to ensure adequate levels of industrial safety and comply with applicable laws, ordinances, regulations, and standards. The conditions of certification in this section of the Final Staff Assessment (FSA), including existing, modified, and new conditions, provide assurance that the Construction Safety and Health Program and the Operations and Maintenance Safety and Health Program proposed by the project owner would be reviewed by the appropriate agencies before implementation. The conditions also require verification that the proposed plans adequately assure worker safety and fire protection and comply with applicable laws, ordinances, regulations, and standards.

Staff has considered the positions of Palen Solar Holdings LLC and the Riverside County Fire Department (RCFD) and has considered all relevant information, including past and current experience at other solar power plants in California. Staff has determined that the modified project would cause a significant direct impact on local fire protection services but would not cause a significant cumulative impact. A direct impact is caused by the need to equip and train the fire department to respond to the specific unique hazards posed by solar tower technology which would be new to the county. No significant cumulative impact would occur because 1) the construction and operation of this solar power plant is not likely to change the overall hazard profile of facilities requiring emergency response in the county, 2) emergency events at this solar power plant are not likely to escalate (i.e., spread to other structures or locations) within or beyond the power plant site, and 3) emergencies are not likely to occur simultaneously with other facilities.

Therefore, staff is proposing mitigation to reduce the direct impact to less than significant by requiring payment to the RCFD for capital improvements and annual support (see proposed revised Condition of Certification **WORKER SAFETY-7**). Staff is also proposing a new Condition of Certification (**WORKER SAFETY-10**) that would clarify the requirement for the project owner to submit plans for all fire detection and suppression systems to the RCFD and to pay the fire department's usual and customary fee for those reviews and subsequent inspections.

In order to protect workers from potential exposure to Valley Fever (VF), staff proposes a revision to existing Condition of Certification, now numbered **WORKER SAFETY-8**, which would require enhanced dust control measures. Additionally, staff proposes Condition of Certification **WORKER SAFETY-12**, which would require reporting of confirmed VF cases (along with heat stress incidences) to the Energy Commission staff.

Staff proposes a new Condition of Certification (**WORKER SAFETY-11**) that would require two Tower Access and Safety Plans, one for construction and one for commissioning and operations, be prepared and implemented to control access to the towers, address fire detection and suppression systems, and ensure that the emergency hoist systems and backup power supply for the elevators and hoists are in place

Lastly, staff deleted and revised various conditions that pertained to design features of the previously approved Palen project.

INTRODUCTION

Worker safety and fire protection is regulated through laws, ordinances, regulations, and standards (LORS), at the federal, state, and local levels. Industrial workers at the facility operate equipment and handle hazardous materials daily and may face hazards that can result in accidents and serious injury. Protection measures are employed to eliminate or reduce these hazards or to minimize the risk through special training, protective equipment, and procedural controls.

The purpose of this Final Staff Assessment (FSA) is to assess the worker safety and fire protection measures proposed by the PSEGS and to determine whether the project owner has proposed adequate measures to:

- comply with applicable safety LORS;
- protect the workers during construction and operation of the facility;
- protect against fire; and
- Provide adequate emergency response procedures.

METHODOLOGY AND THRESHOLDS FOR DETERMINING ENVIRONMENTAL CONSEQUENCES

Two issues are assessed in **Worker Safety and Fire Protection**:

- the potential for impacts on the safety of workers during demolition, construction, and operations activities, and
- Fire prevention/protection, emergency medical response, and hazardous materials spill response during construction and operations.

Worker safety issues are thoroughly addressed by the California Department of Occupational Safety and Health (Cal/OSHA) regulations. If all LORS are followed, workers will be adequately protected. Thus, the standard for staff's review and determination of significant impacts on workers is whether or not the project owner has demonstrated adequate knowledge about and dedication to implementing all pertinent and relevant Cal/OSHA standards.

Regarding fire prevention matters, staff reviews and evaluates the on-site fire-fighting systems proposed by the project owner and the time needed for off-site local fire departments to respond to a fire, medical, or hazardous material emergency at the proposed power plant site. If on-site systems do not follow established codes and industry standards, staff recommends additional measures. Staff reviews and evaluates the local fire department capabilities and response time in each area and interviews the local fire officials to determine if they feel adequately trained, manned, and equipped to respond to the needs of a power plant. Staff then determines if the presence of the power plant would cause a significant impact on a local fire department. If it does, staff will recommend that the project owner mitigate this impact by providing increased resources to the fire department.

Staff has also established a procedure when a local fire department has identified either a significant incremental project impact to the local agency or a significant incremental cumulative impact to a local agency. Staff first conducts an initial review of the position and either agrees or disagrees with the fire department's determination that a significant impact would exist if the proposed power plant is built and operated. A process then starts whereby the project owner can either accept the determination made by staff or refute the determination by providing a Fire Needs Assessment and a Risk Assessment. The Fire Needs Assessment would address fire response and equipment/staffing/location needs while the Risk Assessment would be used to establish that while an impact to the fire department may indeed exist, the risk (chances) of that impact occurring and causing injury or death is less than significant.

LAWS, ORDINANCES, REGULATIONS, AND STANDARDS

Worker Safety and Fire Protection Table 1
Laws, Ordinances, Regulations, and Standards (LORS)

Applicable LORS	Description
Federal	
Title 29 U.S. Code (USC) section 651 et seq (Occupational Safety and Health Act of 1970)	This act mandates safety requirements in the workplace with the purpose of “[assuring] so far as possible every working man and woman in the nation safe and healthful working conditions and to preserve our human resources” (29 USC §651).
Title 29 Code of Federal Regulation (CFR) sections 1910.1 to 1910.1500 (Occupational Safety and Health Administration Safety and Health Regulations)	These sections define the procedures for promulgating regulations and conducting inspections to implement and enforce safety and health procedures to protect workers, particularly in the industrial sector.
29 CFR sections 1952.170 to 1952.175	These sections provide federal approval of California’s plan for enforcement of its own Safety and Health requirements, in lieu of most of the federal requirements found in 29 CFR sections 1910.1 to 1910.1500.
State	
Title 8 California Code of Regulations (Cal Code Regs.) all applicable sections (Cal/OSHA regulations)	These sections require that all employers follow these regulations as they pertain to the work involved. This includes regulations pertaining to safety matters during construction, commissioning, and operations of power plants, as well as safety around electrical components, fire safety, and hazardous materials use, storage, and handling.
24 Cal Code Regs. section 3, et seq.	This section incorporates the current addition of the Uniform Building Code.
Health and Safety Code section 25500, et seq.	This section presents Risk Management Plan requirements for threshold quantity of listed acutely hazardous materials at a facility.
Health and Safety Code sections 25500 to 25541	These sections require a Hazardous Material Business Plan detailing emergency response plans for hazardous materials emergency at a facility.
Local (or locally enforced)	
Riverside County Ordinance 457	Adopts specific building, mechanical, plumbing, and electrical codes from sources such as the California Building Standards Commission with county-specific modifications.
Riverside County Ordinance 787.6	Adopts the 2010 edition of the California Fire Code and portions of the 2010 edition of the California Building Code with county-specific modifications.
Riverside County Ordinance 615	Establishes requirements for the use, generation, storage and disposal of hazardous materials within the County.
Riverside County Department of Environmental Health, Hazardous Materials Releases	Adopts State requirements and guidelines to govern hazardous materials release response plans and inventories.
NFPA 850	This industry standard of the National Fire Protection Association (NFPA) address fire protection at electrical generating stations.
Chapter 22 of the 2010 California Fire Code	This section of the CFC addresses requirement for Motor Fuel-Dispensing Facilities and Repair Garages. It has been adopted by Riverside County and will apply to the fuel depot at the site.
NFPA 30a	This is the NFPA code for Motor Fuel Dispensing Facilities and Repair Garages (2008Edition) and is the industry standard for fuel depots.

PROPOSED MODIFIED PROJECT

On December 17, 2012, Palen Solar Holdings, LLC (PSH) filed a petition with the Energy Commission requesting to modify the Palen Solar Power Project (PSPP) now called PSEGS. The major modification is replacing the parabolic trough solar collection system using heat transfer fluid with Bright Source's solar tower technology. Heliostats—elevated mirrors guided by a tracking system mounted on a pylon—focus the sun's rays on a solar receiver steam generator located atop a 750-foot tower near the center of each solar field to create steam to drive a turbine that generates electricity.

Two adjacent solar fields producing 250 MW each are proposed for a combined nominal output of approximately 500 MW. Each of the 250 MW solar fields would have a dedicated tower, solar field/heliostat array of approximately 85,000 heliostats, and a dedicated steam turbine generator/power block. Both solar fields would share common facilities, including a common area containing an administration building, warehouse, evaporation ponds, maintenance complex, a meter/valve station for incoming natural gas service to the site, an onsite switchyard, and a 10-mile single-circuit 230-kV generation tie-line. Other onsite facilities would include access and maintenance roads (either dirt, gravel, or paved), perimeter fencing, tortoise fencing, and other ancillary security facilities.

SETTING AND EXISTING CONDITIONS

The proposed facility would be located in Riverside County off Interstate 10 approximately 10 miles east of Desert Center, and would consist of two units producing a total output of 500 MW. Fire support services to the site would be under the jurisdiction of the Riverside County Fire Department (RCFD). The closest RCFD fire station to the project site is the Lake Tamarisk Station #49 located at 43880 Lake Tamarisk in Desert Center, about 13 miles from the project. The estimated response time is 14 minutes once dispatched. The next nearest station would be the Blythe Air Base Station #45 located about 40 miles east, with a response time of about 30 minutes once dispatched. The fire station in Indio (Terra Lago Station #87 located at 42900 Golf Center Parkway, about 59 miles west of the PSEGS) would also respond if necessary, with a response time of 45 minutes once dispatched. All RCFD fire stations are staffed full-time with a minimum of three personnel per shift which include paramedics (Solar Millennium 2009a, Section 5.11.2.6 and RCFD 2010a).

The project owner has stated that designated plant personnel would be trained as a hazardous materials response team and that one or more spill response kits would be available on-site (Solar Millennium 2009a, Section 5.6.4.2). In the event of a large incident involving hazardous materials, backup support would be provided by the RCFD, which has a hazmat response unit that is capable of responding to any incident at the proposed PSEGS. The RCFD hazmat unit is located in Palm Desert (about 70 miles away) and would respond within 1.5 to 2 hours (RCFD 2010a).

Worker Safety and Fire Protection Table 2
Fire and Emergency Response for the PSEGS

RCFD Station	Response Time[1]	Distance to PSEGS	EMS/HazMat Capability[2]
Lake Tamarisk Station #49	14 minutes	~13 miles	Y/Y
Blythe Air Base Station #45	30 minutes	~40 miles	Y/Y
Terra Lago Station #87	45 minutes	~59 miles	Y/Y

Notes:
1 - Response times are estimated from the moment of dispatch.
2 - All personnel are trained to EMT-1 level and first responder for hazardous materials incidents.
Source: E-mail communications with the RCFD (RCFD 2010a)

In addition to construction and operations worker safety issues, the potential exists for exposure to contaminated soil during site preparation. The Phase I Environmental Site Assessment conducted for this site in 2009 found no “Recognized Environmental Conditions” per the American Society for Testing and Materials Standards (ASTM) definition. That is, there was no evidence or record of any use, spillage, or disposal of hazardous substances on the site, nor was there any other environmental concern that would require remedial action (Solar Millennium 2009a, Section 5.16.2.3). To address the unlikely possibility that soil contamination would be encountered during construction of the PSEGS, proposed Conditions of Certification **WASTE-2** and **WASTE-3** require a registered professional engineer or geologist to be available during soil excavation and grading to ensure proper handling and disposal of contaminated soil. See the staff assessment section on **WASTE MANAGEMENT** for a more detailed analysis of this topic.

Another potential hazard present at this site is the likelihood of encountering unexploded ordinance (UXOs) left over from large scale military training exercises conducted along what is now the route of Interstate 10 between 1942 and 1945 and in 1964. During WW-II, the area served as part of General George S. Patton’s Desert Training Center (DTC), the largest military facility in the world. As a result of these historic military maneuvers, there is a potential for unexploded ordnance (UXO) to occur at this site. Please see **WASTE MANAGEMENT** for further discussion of this issue. With implementation of Condition of Certification **WASTE-1**, staff concludes that any potential impact to workers from UXO would be reduced to less than significant.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

WORKER SAFETY

Industrial environments are potentially dangerous during construction and operation of facilities. Workers at the proposed PSEGS would be exposed to loud noises, glint and glare, moving equipment, trenches, and confined space entry and egress problems. The workers may experience falls, trips, burns, lacerations, and numerous other injuries. They have the potential to be exposed to falling equipment or structures, chemical spills, hazardous waste, fires, explosions, and electrical sparks and electrocution. It is important for the PSEGS to have well-defined policies and procedures, training, and hazard recognition and control at its facility to minimize such hazards and protect workers. If the facility complies with all LORS and conditions of certification, workers will be adequately protected from health and safety hazards.

A Safety and Health Program would be prepared by the project owner to minimize worker hazards during construction and operation. Staff uses the phrase “Safety and Health Program” to refer to the measures that would be taken to ensure compliance with the applicable LORS during the construction and operational phases of the project.

Construction Safety and Health Program

Workers at the PSEGS would be exposed to hazards typical of construction and operation of a solar thermal electric power generating facility.

Construction Safety Orders are published at Title 8 California Code of Regulations sections 1502, et seq. These requirements are promulgated by Cal/OSHA and would be applicable to the construction phase of the project. The Construction Safety and Health Program would include the following:

- Construction Injury and Illness Prevention Program (8 Cal Code Regs. §1509)
- Construction Fire Prevention Plan (8 Cal Code Regs. §1920)
- Personal Protective Equipment Program (8 Cal Code Regs. §§1514-1522)
- Emergency Action Program and Plan

Additional programs under General Industry Safety Orders (8 Cal Code Regs. §§3200 to 6184), Electrical Safety Orders (8 Cal Code Regs. §§2299 to 2974) and Unfired Pressure Vessel Safety Orders (8 Cal Code Regs. §§450 to 544) would include:

- Electrical Safety Program
- Motor Vehicle and Heavy Equipment Safety Program
- Forklift Operation Program
- Excavation/Trenching Program
- Fall Protection Program
- Scaffolding/Ladder Safety Program
- Articulating Boom Platforms Program
- Crane and Material Handling Program
- Housekeeping and Material Handling and Storage Program
- Respiratory Protection Program
- Employee Exposure Monitoring Program
- Hand and Portable Power Tool Safety Program
- Hearing Conservation Program
- Back Injury Prevention Program
- Ergonomics Program
- Heat and Cold Stress Monitoring and Control Program
- Hazard Communication Program

- Lock Out/Tag Out Safety Program
- Pressure Vessel and Pipeline Safety Program
- Solar Components Safe Handling Program

The Application for Certification (AFC) includes adequate outlines of each of the above programs (Solar Millennium 2009a, Section 5.18.3.1). Prior to the start of construction of PSEGS, detailed programs and plans would be provided to the Energy Commission Compliance Project Manager (CPM) and to the RCFD pursuant to the Condition of Certification **WORKER SAFETY-1**.

Operations and Maintenance Safety and Health Program

Prior to the start of operations at PSEGS, the Operations and Maintenance Safety and Health Program would be prepared. This operational safety program would include the following programs and plans:

- Injury and Illness Prevention Program (8 Cal Code Regs. §3203)
- Fire Protection and Prevention Program (8 Cal Code Regs. §3221)
- Personal Protective Equipment Program (8 Cal Code Regs. §§3401 to 3411)
- Emergency Action Plan (8 Cal Code Regs. §3220)

In addition, the requirements under General Industry Safety Orders (8 Cal Code Regs. §§3200 to 6184), Electrical Safety Orders (8 Cal Code Regs. §§2299 to 2974) and Unfired Pressure Vessel Safety Orders (8 Cal Code Regs. §§450 to 544) would be applicable to the project. Written safety programs for PSEGS, which the project owner would develop, would ensure compliance with the above-mentioned requirements.

The AFC includes adequate outlines of the Injury and Illness Prevention Program, Emergency Action Plan, Fire Prevention Program, and Personal Protective Equipment Program (Solar Millennium 2009a, Section 5.18.3). These outlines are still applicable to PSEGS Prior to operation of PSEGS, all detailed programs and plans would be provided to the CPM and RCFD pursuant to Condition of Certification **WORKER SAFETY-2**.

Safety and Health Program Elements

As mentioned above, the project owner provided the proposed outlines for both a Construction Safety and Health Program and an Operations Safety and Health Program. The measures in these plans are derived from applicable sections of state and federal law. Both safety and health programs would be comprised of six more specific programs and would require major items detailed in the following paragraphs.

Injury and Illness Prevention Program

The IIPP would include the following components as presented in the AFC and are still applicable to PSEGS (Solar Millennium 2009a, Section 5.18.3.1):

- identity of person(s) with authority and responsibility for implementing the program;
- safety and health policy of the plan;

- definition of work rules and safe work practices for construction activities;
- system for ensuring that employees comply with safe and healthy work practices;
- system for facilitating employer-employee communications;
- procedures for identifying and evaluating workplace hazards and developing necessary program(s);
- methods for correcting unhealthy/unsafe conditions in a timely manner;
- safety procedures; and
- Training and instruction.

Fire Prevention Plan

California Code of Regulations requires an Operations Fire Prevention Plan (8 Cal Code Regs. §3221). The AFC outlines a proposed Fire Prevention Plan which is acceptable to staff for the PSEGS project (Solar Millennium 2009a, Section 5.18.3.2). The plan would accomplish the following:

- determine general program requirements (scope, purpose, and applicability);
- determine potential fire hazards;
- develop good housekeeping practices and proper handling and materials storage;
- determine potential ignition sources and control measures for these sources;
- determine persons responsible for equipment and system maintenance;
- locate portable and fixed fire-fighting equipment in suitable areas;
- establish and determine training and instruction requirements; and
- define recordkeeping requirements.

Under the existing license for the project, the project owner is required to submit a final Fire Prevention Plan to the CPM for review and approval and to the RCFD for review and comment to satisfy Conditions of Certification **WORKER SAFETY-1** and **WORKER SAFETY-2**. Staff is recommending that the Best Management Practices for the storage and application of herbicides be removed from Condition of Certification **WORKER SAFETY-2** because herbicides are not proposed to be used to control vegetation in the heliostat field. No other changes are being made to these two conditions.

Personal Protective Equipment Program

California regulations require Personal Protective Equipment (PPE) and first aid supplies whenever hazards are present that, due to process, environment, chemicals or mechanical irritants, can cause injury or impair bodily function as a result of absorption, inhalation, or physical contact (8 Cal Code Regs. §§ 3380 to 3400). The PSEGS operational environment would require PPE.

All safety equipment must meet National Institute of Safety and Health (NIOSH) or American National Standards Institute (ANSI) standards and would carry markings, numbers, or certificates of approval. Respirators must meet NIOSH and Cal/OSHA standards. Each employee must be provided with the following information pertaining to the protective clothing and equipment:

- proper use, maintenance, and storage;
- when to use the protective clothing and equipment;
- benefits and limitations; and
- when and how to replace the protective clothing and equipment.

The PPE Program ensures that employers comply with the applicable requirements for PPE and provides employees with the information and training necessary to protect them from potential workplace hazards.

Emergency Action Plan

California regulations require an Emergency Action Plan (8 Cal Code Regs. §3220). The AFC contains a satisfactory outline for an emergency action plan (Solar Millennium 2009a, Section 5.18.3.2).

The outline lists plans to accomplish the following:

- establish scope, purpose, and applicability;
- identify roles and responsibilities;
- determine emergency incident response training;
- develop emergency response protocols;
- specify evacuation protocols;
- define post emergency response protocols; and
- determine notification and incident reporting.

Written Safety Program

In addition to the specific plans listed above, additional LORS called *safe work practices* apply to the project. Both the Construction and the Operations Safety Programs would address safe work practices under a variety of programs. The components of these programs include, but are not limited to, the programs found under the heading "Construction Safety and Health Program" in this Worker Safety and Fire Protection section.

Safety Training Programs

Employees would be trained in the safe work practices described in the above-referenced safety programs.

Additional Safety Issues

This solar power plant would present several unique work environments, the first of which involves a solar field located in the high desert. The solar field features thousands of heliostats (mirrors) that would focus intense solar flux on the top of a 750-foot tower. Workers would inspect the solar array for broken mirrors at least once each day by driving up and down dirt paths between the rows of mirrors and even under the mirrors thus generating dust. Cleaning the mirrors will also be conducted on a routine schedule. All these activities would take place year-round and especially during the summer months of peak solar power generation, when outside ambient temperatures routinely reach 115°F and above.

The project owner had indicated that workers would be adequately trained and protected, but did not included precautions against heat stress. However, the existing Conditions of Certification **WORKER SAFETY-1** and **-2** include a worker heat stress protection plan that implements and expands on existing Cal OSHA regulations (8 CCR 3395). Staff believes that effective implementation of a Heat Stress Protection Plan would mitigate the potential for significant risks to workers from heat during both construction and operations. And because heat illness incidences (including but not limited to heat stress, heat exhaustion, heat stroke, or heat prostration) are not only highly probable in desert environments but have now occurred at desert solar power plants under construction, staff believes it is imperative to keep track of these incidences to ensure that all worker protections are indeed being implemented and are adequate. Therefore, staff proposes new Condition of Certification **WORKER SAFETY-12** which would require the project owner to immediately report all heat-related incidences (regardless of whether they are reportable under OSHA regulations) to the CPM within 24 hours of occurrence. In this manner, staff can have a current data base of occurrences at all desert power plants to assist in determining the adequacy of worker protection.

The second unique work environment involves the need to protect workers from the adverse effects of glint and glare coming from the tower and the heliostats. Staff evaluated effects on-site workers in proximity to the towers or the heliostats in Appendix tt1 – Visual Safety Impact Assessment of the **TRAFFIC AND TRANSPORTATION** section of this FSA. As described in that section, the PSEGS is located in a bright desert environment thereby increasing the potential chance for photochemical eye damage, specifically to the retina. The cumulative daily exposure to workers to the ambient environment combined with the additional potential cumulative effects of heliostat and SRSG exposure puts project workers at risk for retinal damage. To ensure the safety of the workers and others within the project boundaries, staff recommends that personnel protection equipment (PPE) in the form of protective glasses be provided.

Protective glasses have been developed for workers engaged in intense solar field work, tower work, and intense close viewing of the SRSG. There is precedence for the issuance of special safety glasses, for example they have been issued to the operators at Solar Energy Development Center (SEDC), and the Coalinga and Ivanpah solar thermal plants. Staff therefore proposes a modification to both existing Conditions **WORKER SAFETY-1** (Project Construction Safety and Health Program) and **WORKER**

SAFETY-2 (Project Operations and Maintenance Safety and Health Program) to include this requirement.

And the third unique work environment involves working at an elevated enclosed location, the inside and atop the two 750 ft. solar towers. Experience and site visits to the existing nearly 500 ft. towers at the Ivanpah facility demonstrate the need for the project owner to address this unique work environment. Worker access to the towers must be controlled and monitored so that it is known at all times and with great precision the number of workers inside the towers. Wood near-fire - smoldering - events have occurred in the more open steel-structure towers at Ivanpah and the ability to detect and suppress such a fire in the more closed concrete towers proposed for the PSGES will require more scrutiny and safety procedures. And since the only method of rescue from inside or from the top of these towers would be via the internal elevator (fire department ladder trucks can reach only to ~100 ft.), the need for a safe and effective elevator system and emergency hoist system becomes paramount.

Staff requested additional information about the towers' safety controls from the owner and the reply (Palen 2013ss) indicated that neither detailed nor schematic drawings of the structures have been developed at this time, but the final layout and design would meet all applicable LORS and be subject to review by the CBO. The response indicated that the following safety measures would be implemented:

1. Tower Access would be provided by a rack-and-pinion industrial-type elevator and a staircase.

2. The elevators would be connected to both grid power, and to the plant essential services bus bar powered by an emergency backup diesel generator. The elevators would also have centrifugal braking in the drive unit upon power failure.

3. A fire detection system would be designed and erected per code in the Electrical Equipment Module (electrical room), which would also be equipped with a dry powder extinguisher. Detection system alarms would be generated to plant operation systems and personnel, and addressees as agreed with the Fire Marshal. A water-based fire suppression system would not be needed as there are no especially flammable materials or unusual potential ignition sources in the tower and SRSG.

4. No workers would be stationed at the top of the tower during routine operation. However, the area may be accessed on occasion for maintenance (typically electrical or instrumentation work or checks, and occasionally circulation pump maintenance).

5. A detailed emergency response plan would be created after detailed design of the tower and its internal systems are further developed.

Staff agrees mostly with the petitioner's safety procedures and therefore proposes new Condition of Certification **WORKER SAFETY-11** to require that these safety measures be incorporated into two Tower Access and Safety Plans, one for construction and one for commissioning/operations, that would address controlled access to the towers, fire detection and suppression systems, elevator operations, the planned emergency hoist systems, and backup power supply for the elevators and hoists.

In summary, staff recommends adoption of revised Condition of Certification **WORKER SAFETY- 1** (Project Construction Safety and Health Program), revised Condition of Certification **WORKER SAFETY-2** (Project Operations and Maintenance Safety and Health Program), and new Condition of Certification **WORKER SAFETY-11** (Tower Access and Safety Plan) which are designed to insure that workers in the solar field and towers have a safe work environment and receive and wear the appropriate personal protective equipment including protective sunglasses.

Another worker safety issue has surfaced based upon experience at the Ivanpah solar power plant. During the summer months in what is referred to as the "monsoon season", sub-tropical weather fronts enter the desert southwest from the south and bring intense storms with extremely heavy rainfall over very brief periods of time. These storms are mostly unpredictable and flash floods can result from the dropping of high amounts of water (inches of rain) in a very short time onto the desert floor resulting in high levels of run-off in otherwise dry washes. The force of moving water in a flash flood is often underestimated and workers at a desert solar power plant site may attempt to drive or walk through the swift flows to cross it. However, as little as two feet of water is enough to carry away most passenger vehicles and swiftly moving water six inches deep can cause a person to lose balance (NOAA 2005). A review of Figure 15 from the Soil and Water section of this FSA shows that although the administration building and both power blocks are outside of the large desert washes, the paved main access road connecting the power blocks and several other internal unpaved roads are located within washes and thus would be expected to flood during heavy precipitation events.

To avoid injury or death during a flood event, staff proposes to modify Conditions of Certification **WORKER SAFETY-1** and **WORKER SAFETY-2** to include a Construction Flood Safety Plan and an Operations Flood Safety Plan. These Plans would provide requirements and guidance to on-site workers with respect to avoiding injury or death during a very large flood event (100-year flooding or larger). The Plans would be submitted to the Energy Commission for review and approval and include the following:

- Specific actions to be completed during a very large flood event in order to protect workers.
- Identified flood refuge areas that would not be susceptible to 100-year flooding.
- Requirements that all on-site workers implement the Plan and that the Plan be updated, as needed, during the life of the project.

Additional Mitigation Measures

Protecting construction workers from injury and disease is among the greatest challenges in occupational safety and health. The following facts are reported by the National Institute for Occupational Safety and Health (NIOSH):

- More than 7 million persons work in the construction industry, representing 6 percent of the labor force. Approximately 1.5 million of these workers are self-employed.
- Of approximately 600,000 construction companies, 90 percent employ fewer than 20 workers. Few have formal safety and health programs.
- From 1980 to 1993, an average of 1,079 construction workers were killed on the job each year—more fatal injuries than in any other industry.
- Falls caused 3,859 construction worker fatalities (25.6 percent) between 1980 and 1993.
- Construction injuries account for 15 percent of workers' compensation costs.
- Assuring safety and health in construction is complex, involving short-term work sites, changing hazards, and multiple operations and crews working in close proximity.
- In 1990, Congress directed NIOSH to undertake research and training to reduce diseases and injuries among construction workers in the United States. Under this mandate, NIOSH funds both intramural and extramural research projects.

The hazards associated with the construction industry are thus well documented. These hazards increase in complexity in the multi-employer worksites typical of large, complex, industrial-type projects such as the construction of solar power plants. In order to reduce and/or eliminate these hazards, it has become standard industry practice to hire a Construction Safety Supervisor to ensure a safe and healthful environment for all personnel. That this standard practice has reduced and/or eliminated hazards has been evident in the audits staff recently conducted of power plants under construction. The federal Occupational Safety and Health Administration (OSHA) has also entered into strategic alliances with several professional and trade organizations to promote and recognize safety professionals trained as Construction Safety Supervisors, Construction Health and Safety Officers, and other professional designations. The goal of these partnerships is to encourage construction subcontractors in four areas:

- to improve their safety and health performance;
- to assist them in striving for the elimination of the four hazards (falls, electrical, caught in/between and struck-by hazards), which account for the majority of fatalities and injuries in this industry and have been the focus of targeted OSHA inspections;
- to prevent serious accidents in the construction industry through implementation of enhanced safety and health programs and increased employee training; and
- to recognize those subcontractors with exemplary safety and health programs.

To date, there are no OSHA or Cal/OSHA requirements that an employer hire or provide for a Construction Safety Officer. OSHA and Cal/OSHA regulations do, however, require that safety be provided by an employer and the term *Competent Person* is used in many OSHA and Cal/OSHA standards, documents, and directives. A Competent Person is usually defined by OSHA as an individual who, by way of training and/or experience, is knowledgeable of standards, is capable of identifying workplace hazards relating to the specific operations, is designated by the employer, and has authority to take appropriate action. Condition of Certification **WORKER SAFETY-3** requires that the project owner to designate and provide for a power plant site Construction Safety Supervisor which serves as the Competent Person as required by OSHA and Cal/OSHA. Staff does not propose any changes to this condition.

As discussed above, the hazards associated with the construction industry are well documented. These hazards increase in complexity in the multi-employer worksites typical of large, complex, industrial-type projects such as the construction of solar power plants.

Accidents, fires, and a worker death have occurred at Energy Commission-certified power plants in the past due to the failure to recognize and control safety hazards and the inability to adequately supervise compliance with occupational safety and health regulations. Safety problems have been documented by Energy Commission staff in safety audits conducted in 2005 at several power plants under construction. The findings of the audit staff include, but are not limited to, such safety oversights as:

- lack of posted confined space warning placards/signs;
- confusing and/or inadequate electrical and machinery lockout/tagout permitting and procedures;
- confusing and/or inappropriate procedures for handing over lockout/tagout and confined space permits from the construction team to commissioning team and then to operations;
- dangerous placement of hydraulic elevated platforms under each other;
- inappropriate placement of fire extinguishers near hotwork;
- dangerous placement of numerous power cords in standing water on the site, thus increasing the risk of electrocution;
- construction of an unsafe aqueous ammonia unloading pad;
- inappropriate and unsecure placement of above-ground natural gas pipelines inside the facility but too close to the perimeter fence; and
- lack of adequate employee- or contractor-written training programs addressing proper procedures to follow in the event of finding suspicious packages or objects either on or off-site.

In order to reduce and/or eliminate these hazards, it is necessary for the Energy Commission to have a professional Safety Monitor on-site to track compliance with Cal/OSHA regulations and periodically audit safety compliance during construction, commissioning, and the hand-over to operational status. These requirements are outlined in existing Condition of Certification **WORKER SAFETY-4**. A Safety Monitor, hired by the project owner, yet reporting to the Chief Building Official (CBO) and CPM, will serve as an “extra set of eyes” to ensure that safety procedures and practices are fully implemented at all power plants certified by the Energy Commission. During the audits conducted by staff, most site safety professionals welcomed the audit team and actively engaged it in questions about the team’s findings and recommendations. These safety professionals recognized that safety requires continuous vigilance and that the presence of an independent audit team provided a fresh perspective of the site. Staff does not propose any changes to **WORKER SAFETY-4**.

Valley Fever (Coccidioidomycosis)

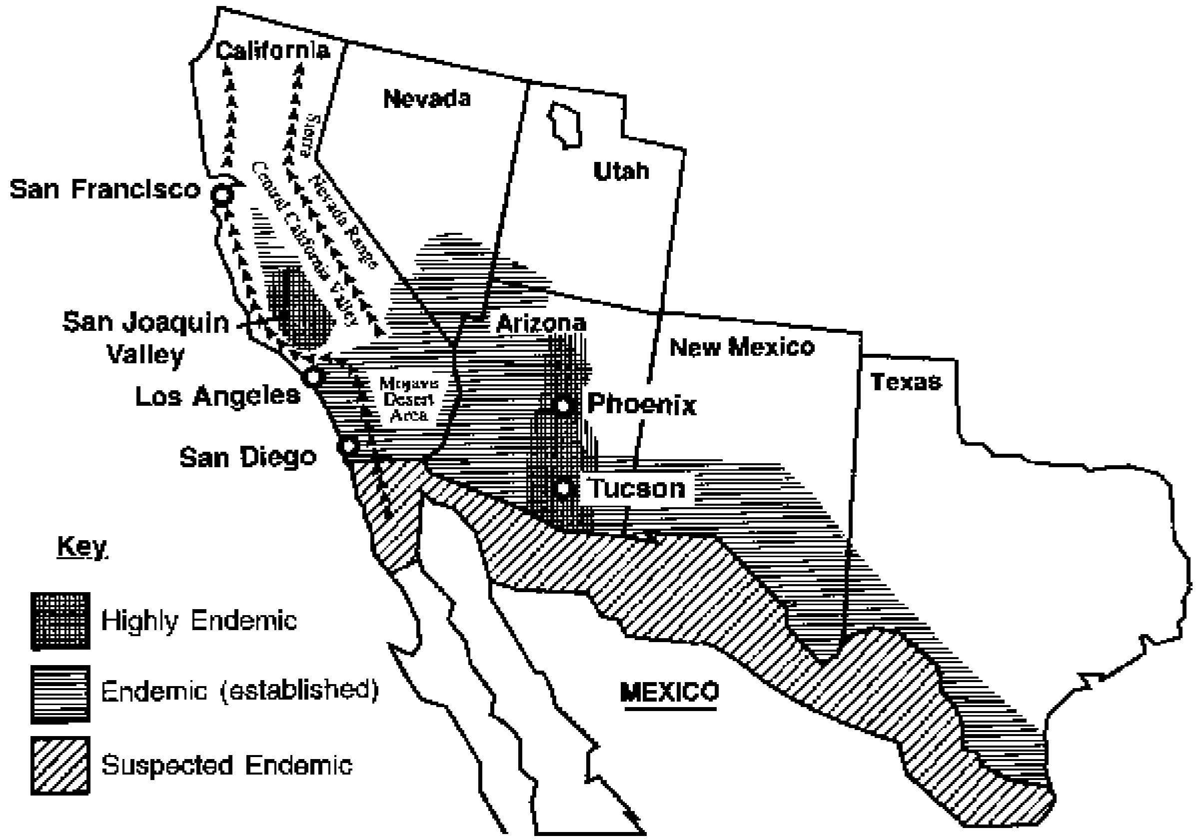
Coccidioidomycosis or "Valley Fever" (VF) is primarily encountered in southwestern states, particularly in Arizona and California (see **Worker Safety and Fire Protection Figures 1** and **2**). It is caused by inhaling the spores of the fungus Coccidioides immitis, which are released from the soil during soil disturbance (e.g., during construction activities) or wind erosion. The disease usually affects the lungs and can have potentially severe consequences, especially in at-risk individuals such as the elderly, pregnant women, and people with compromised immune systems. Trenching, excavation, and construction workers are often the most exposed population. Treatment usually includes rest and antifungal medications. No effective vaccine currently exists for VF. VF is endemic to the San Joaquin Valley in California, which presumably gave this disease its common name. In California, the highest VF rates are recorded in Kern, Kings, and Tulare Counties, followed by Fresno and San Luis Obispo Counties. LA County, San Diego County, San Bernardino County, and Riverside County also have reported VF cases although much fewer.

In October 2007, a construction crew excavated a trench for a new water pipe in California. Within three weeks, 10 of 12 crew members developed Valley Fever) with 7 of the 10 displaying abnormal chest x-rays, four had rashes, and one had an infection that had spread beyond his lungs and affected his skin (Das, Rupali et al. 2012). Over the next few months, the ten ill crew members missed at least 1660 hours of work and two workers were on disability for at least five months. A February 2013 outbreak of VF affecting at least 28 workers at a photovoltaic solar plant in eastern San Luis Obispo County, along with an increase in inmates at two San Joaquin Valley prisons coming down with the disease, has sparked renewed interest and concern. (The California Department of Public Health, Cal-OSHA, and San Luis Obispo County are investigating that outbreak.) The interest is high enough for the California State Senate to declaring the month of August 2013 as Valley Fever Awareness Month. This designation appears justified in that although California does not yet have an official statewide method of tracking the rate of Valley Fever infections, infection rates in California and Arizona have risen 400 percent in the last 10-year reporting period, from an estimated 31 cases for every 100,000 people in 1999 to 157 cases for every 100,000 people in 2011 and the number of cases in Kern County alone has more than tripled from 2009 to a total of 2,051 cases in 2010 and 2,734 cases in 2011 (MMWR 2013).

The Centers for Disease Control and Prevention also reports that the total number of VF cases nationwide rose by nearly 900 percent from 1998 to 2011 (MMWR 2013). Researchers don't have a good explanation for the dramatic increase even when accounting for growing populations throughout the Southwest, although when soil is dry and it is windy, more spores are likely to become airborne in endemic areas, according to Dr. Gil Chavez, Deputy Director of the Center for Infectious Diseases at the California Department of Public Health.

A recent report from the U.S. Centers for Disease Control (CDC 2012, MMWR 2013) showed that the rise in VF incidence has resulted in it being a major cause of community-acquired pneumonia in California and the southwestern U.S. The CDC found that in 2011, more than 20,000 cases were reported in the U.S., twice as many cases as tuberculosis. Nearly 75 percent of people who get VF miss work or school due to their illness, and more than 40 percent of people who get VF need to be hospitalized. In Ventura County after the Northridge earthquake of 1994, 203 cases including 3 deaths occurred with most of the cases occurring in the town of Simi Valley. In 2001, at least 7 people attending the World Championship of Model Airplane Flying in Lost Hills in Kern County developed VF after attending this event for only a few days. And at the Taft Correctional Facility in Kern County, 88 cases were identified from 2003-04. In 2011 (last full year of data), 5697 cases in California were reported to public health officials.

Worker Safety and Fire Protection Figure 1
Geographic Distribution of Coccidioidomycosis*



*Source: CDC 2006, Figure 2

Worker Safety and Fire Protection Figure 2
Geographic Distribution of Coccidioidomycosis in California

Source: Valley Fever Fact Sheet, California Dept. of Public Health. June 2013

A 2004 CDC report attributed increases in California and Arizona prior to 2004 to changes in land use, demographics, and climate in endemic areas, although certain cases might be attributable to increased physician awareness and testing (CDC 2006). According to the CDC Morbidity and Mortality Weekly Report of February 2009, Kern County experienced the highest incidence rates (150 cases per 100,000 population), and non-Hispanic blacks having the highest hospitalization rates (7.5 per 100,000 population).

Public health officials have tried to explain the sudden increase in Coccidioidomycosis cases that began in the early 1990's. They found that the San Joaquin Valley in California has the largest population of C. immitis, which is found to be distributed unevenly in the soil and seems to be concentrated around animal burrows and ancient Indian burial sites. It is usually found 4 to 12 inches below the surface of the soil. The paper also reported that incidences of coccidioidomycosis vary with the seasons; with highest rates in late summer and early fall when the soil is dry and the crops are harvested. Dust storms are frequently followed by outbreaks of coccidioidomycosis (Kirkland 1996). A modeling attempt to establish the relationship between fluctuations in VF incident rates and weather conditions in Kern County found that there is only a weak connection between weather and VF cases (weather patterns correlate with up to 4 percent of outbreaks). One study concluded that the factors that cause fluctuations in VF cases are not weather-related but rather biological and anthropogenic (i.e. human activities, primarily construction on previously undisturbed soil) (Talamantes 2007).

In correspondence with Dr. Michael MacLean of the Kings County Health Department, he noted that according to his experience and of those who study VF, it is very hard to find the fungus in soil that was previously farmed and irrigated, which greatly reduces the risk of infection resulting from disturbance of farmed lands. This does not apply to previously undisturbed lands where excavation, grading, and construction may correlate with increases in VF cases. Dr. MacLean feels that with the current state of knowledge, we can only speculate on the causes and trends influencing VF cases and he does not feel that construction activities are necessarily the cause of VF outbreaks (KCEHS 2009).

VF is spread through the air. If soil containing the fungus is disturbed by construction, natural disasters, or wind, the fungal spores get into the air where people can breathe in the spores. The disease is not spread from person to person. Occupational or recreational exposure to dust is an important consideration. Agricultural workers, construction workers, or others (such as archeologists) who dig in the soil in the disease-endemic area of the Central Valley are at the highest risk for the disease (CDC 2006; CDHS 2010). The risk for disseminated coccidioidomycosis is much higher among some ethnic groups, particularly African-Americans and Filipinos. In these ethnic groups, the risk for disseminated coccidioidomycosis is tenfold that of the general population (CDC 2006) (see **Worker Safety and Fire Protection Table 3,** Disease Forms of Valley Fever).

Worker Safety and Fire Protection Table 3
Disease Forms of Valley Fever

Categories	Notes
Asymptomatic	• Occurs in about 50 percent of patients
Acute Symptomatic	• Pulmonary syndrome that combines cough, chest pain, shortness of breath, fever, and fatigue. • Diffuse pneumonia affects immunosuppressed individuals • Skin manifestations include fine papular rash, erythema nodosum, and erythema multiforme • Occasional migratory arthralgias and fever
Chronic Pulmonary	• Affects between 5 to 10% of infected individuals • Usually presents as pulmonary nodules or peripheral thin-walled cavities
Extrapulmonary/Disseminated Varieties	
Chronic skin disease	• Keratotic and verrucose ulcers or subcutaneous fluctuant abscesses
Joints / Bones	• Severe synovitis and effusion that may affect knees, wrists, feet, ankles, and/or pelvis • Lytic lesions commonly affecting the axial skeleton
Meningeal Disease	• The most feared complication • Presenting with classic meningeal symptoms and signs • Hydrocephalus is a frequent complication
Others	• May affect virtually any organ, including thyroid, GI tract, adrenal glands, genitourinary tract, pericardium, peritoneum

Given the available scientific and medical literature on VF and the recent outbreaks in California, it is clear that the potential for VF to impact workers during construction and operation of the proposed PSEGS is very high. To minimize this potential exposure of workers and also the public to coccidioidomycosis during soil excavation and grading, extensive wetting of the soil prior to and during construction activities should be employed and dust masks should be worn at certain times during these activities. The dust (PM10) control measures found in the Air Quality section of the SA/RSA should be strictly adhered to in order to adequately reduce the risk of contracting VF to less than significant. Towards that, staff proposes revised Condition of Certification **WORKER SAFETY-8** which would require that the dust control measures found in proposed Conditions **AQ-SC3** and **AQ-SC4** be supplemented with additional requirements including implementing additional monitoring methods.

And because VF incidences are not only probable in desert environments but have now occurred at a solar PV power plant under construction in another very arid part of the state (and not under the licensing authority of the Energy Commission), staff believes it is imperative to keep track of these incidences to ensure that all worker protections are indeed being implemented and are adequate. Therefore, staff proposes new Condition of Certification **WORKER SAFETY-12** which would require the project owner to report all verified incidences of VF in all workers at the site to the CPM within 24 hours of receiving notification from a medical professional that the worker does indeed have VF. In this manner, staff can have an up-to-date data base of occurrences at all desert power plants to assist in determining the adequacy of worker protection.

FIRE HAZARDS

During construction and operation of the proposed PSEGS project, there is the potential for both small fires and major structural fires. Electrical sparks, combustion of fuel oil, hydraulic fluid, mineral oil, insulating fluid at the power plant switchyard or flammable liquids, explosions, and over-heated equipment, may cause small fires. Major structural fires in areas with automatic fire detection and suppression systems are unlikely to develop at power plants. Compliance with all LORS and providing mitigation to the RCFD would be adequate to assure protection from all fire hazards.

Staff reviewed the information provided in the AFC and the Fire and Emergency Services Risk Assessment, and spoke to representatives of the RCFD to determine if available fire protection services and equipment would adequately protect workers and to determine the project's impact on fire protection services in the area. The PSEGS will rely on both on-site fire protection systems and local fire protection services. The on-site fire protection system provides the first line of defense for small fires. The on-site system for the power blocks and common area are the same regardless of the type of solar generating system used (parabolic trough or tower). In the event of a major fire, fire support services, including trained firefighters and equipment for a sustained response, would be provided by the RCFD (RCFD 2010a).

Construction

During construction, the permanent fire protection systems proposed for the PSEGS would be installed as soon as practical; until then portable fire extinguishers would be placed throughout the site at appropriate intervals and periodically maintained. Safety procedures and training would be implemented according to the guidelines of the Construction Fire Protection and Prevention Plan (Solar Millennium 2009a, Section 5.18.3.1).

The project owner has also indicated that it intends to construct and operate a concrete batch plant and an above-ground fuel depot on the site during construction. The fuel depot (which may remain in service during operations) will contain a maximum of 20,000 gallons of diesel fuel and 500 gallons of gasoline (Galati & Blek2010i, Revised Project Description).The concrete batch plant will be required to have additional fire detection and suppression systems that will be reviewed and evaluated by the Riverside County Fire Marshall and the Energy Commission CPM.

The fire protection measures that are required by code for the fuel depot and dispensing facility include:

- Chapter 22 of the 2007 California Fire Code: Motor Fuel-Dispensing Facilities and Repair Garages (formally adopted by Riverside County)
- NFPA 30a: Code for Motor Fuel Dispensing Facilities and Repair Garages (2008Edition)

Applicable sections of the 2007 Ca Fire Code and NFPA 30a are very similar; however NFPA 30a contains more details for fuel tank design specifications and other requirements. The requirements listed in these codes include the materials to be used to construct fuel tanks, location of dispensing devices, spacing from other structures, fencing, physical protective barriers, shut-off valves, emergency relief venting, secondary containment, vapor and liquid detection systems with alarms, and other general design requirements.

NFPA 30a requires the following:

- 7.3.5 Fixed Fire Protection.
- 7.3.5.1 For an unattended, self-serve, motor fuel dispensing facility, additional fire protection shall be provided where required by the *authority having jurisdiction.(italics added)*
- 7.3.5.2 Where required, an automatic fire suppression system shall be installed in accordance with the appropriate NFPA standard, manufacturers' instructions, and the listing requirements of the systems.
- 9.2.5 Basic Fire Control.
- 9.2.5.1 Sources of Ignition. Smoking materials, including matches and lighters, shall not be used within 6m (20 ft) of areas used for fueling, servicing fuel systems…
- 9.2.5.2 Fire Extinguishers. Each motor fuel dispensing facility or repair garage shall be provided with fire extinguishers installed, inspected, and maintained as required by NFPA 10, *Standard for Portable Fire Extinguishers.* Extinguishers for outside motor fuel dispending areas shall be provided according to the extra (high) hazard requirements for Class B hazards, except that the maximum travel distance to an 80 B:C extinguisher shall be permitted to be 30.48m (100 feet).
- 9.2.5.3 Fire Suppression Systems. Where required, automatic fire suppression systems shall be installed in accordance with appropriate NFPA standard, manufacturer's instructions, and the listing requirements of the systems.

The authority having jurisdiction is the Energy Commission and the RCFD which will review and comment on the fire detection and suppression plans for the fuel depot before it is built and operated.

The only fire protection measure explicitly listed in the CA Fire Code is a requirement for fire extinguishers to be located within 75 feet of the fuel dispensing equipment. Neither the CFC nor the Riverside County codes require sprinkler systems for fuel dispensing facilities. Section 2203.2 of the CFC requires an approved, clearly identified and readily accessible emergency disconnect switch at an approved location to stop the transfer of fuel to the fuel dispensers in the event of a fuel spill or other emergency. Section 2205.3 requires spill control to prevent liquids spilled during dispensing operations from flowing into buildings and section 2206.5 requires that above-ground tanks be provided with secondary containment in the form of drainage control or placement of berms or dikes in accordance with Chapter 34. The project owner has proposed to install secondary containment.

Staff has assessed the proposed concrete batch plant and fuel depot and has determined that the project owner intends to meet all codes and standards in their operations of the batch plant and fuel depot. Existing Condition of Certification **WORKER SAFETY-1** would require the RCFD to review and the CPM to review and approve the fire protection systems for the fuel depot.

Operation

The information in the AFC indicates that the project intends to meet the fire protection and suppression requirements of the 2007 California Fire Code, all applicable recommended NFPA standards (including Standard 850 addressing fire protection at electric generating plants), and all Cal/OSHA requirements, with the exception of providing a secondary access road and gate for emergency response vehicles. The proposed PSEGS has only one access point, that being through the main gate (via a new paved access road from an I-10 interchange), and the AFC and the Petition to Amend make no mention of needing a secondary access road to the site or another access gate through the perimeter fence (Solar Millennium 2009a, Section 2.5.6.5, Palen 2012a). Indeed, the Petition requests that the requirement for a second access road found in existing Condition of Certification **WORKER SAFETY-6** be removed. Both the California Fire Code (24 CCR Part 9, chapter 5, section 503.1.2) and the Uniform Fire Code (sections 901 and 902) require that access to the site be reviewed and approved by the fire department, and the RCFD stated that a second road and gate for fire and emergency responders is required for this site (RCFD 2010b).

Staff originally recommended that a second access road and access gate was necessary to ensure fire department and other emergency response access should the main road or main gate be blocked. Additionally, the fire department may wish to suppress a fire from multiple sides and access to another part of the site would be needed. A second access road and gate is a standard requirement of the California Fire Code and NFPA codes and existing Condition of Certification **WORKER SAFETY-6** requires such a road.

However, there are several site-specific reasons why staff is not now recommending a second emergency access road but is instead recommending at least two emergency access gates (one each on the north fence line and the south fence line).

First, the removal of heat transfer fluid (HTF) and propane from the proposed modified project lowers the fire risk significantly. And although the need for rescue and high-structure fire fighting has been significantly elevated with the proposed towers in the modified project, the need to obtain access from different sides is greatly reduced. But just as important, various site-specific issues render the placement of a secondary access road problematical.

From a biological perspective, there are several constraints to be considered when siting the secondary access road. Desert tortoise critical habitat occurs north of the I-10 freeway, along the southwestern perimeter of the project site. Development within critical habitat is not desired, and can be costly given the 5:1 mitigation ratio. Additionally, large vegetated ephemeral washes flow across the area likely to be impacted by a secondary access road. Development within washes disrupts natural processes, adversely impacting wildlife and the greater ecosystem by increasing sedimentation, increasing the number of nonnative plants, and destruction of rare microphyll vegetation within and along the washes, which recuperate very slowly under desert conditions. Impacts to desert dry wash woodland are typically mitigated at a 3:1 ratio. For any alignment chosen, thorough and time-consuming surveys of existing would need to be performed as per the following partial list:

- Jurisdictional Delineation (CDFG Code 1600)
- Protocol desert tortoise surveys
- General wildlife surveys
- General botanical surveys
- Rare plant surveys
- Burrowing owl surveys

In order to comply with the requirements of LORS, staff proposes modifications to Condition of Certification **WORKER SAFETY-6** that would require the project owner to provide at least two secondary access gates for emergency vehicles to enter the site from around the perimeter in the event the main access road is blocked, and to ensure that all roads are capable of supporting a 60,000 pound fire engine. There must be at least two access gates equipped with either a keypad or key for fire department and other emergency response personnel to open the gate. The RCFD, the California Highway Patrol, and the Riverside County Sheriff's Department shall be given access to these gates. In the event of an emergency that requires the RCFD to enter the site through these gates, the RCFD will be able to access the gate by using their two all-terrain fire engines that were purchased for them by the Genesis Solar Energy Project. PSEGS will be required by **WORKER SAFETY-6** to "buy-into" these specialized fire engines by paying one-half the costs (payable to Genesis) and one-half the annual operating/maintenance costs (payable to Genesis).

Fire suppression elements in the proposed plant would include both fixed and portable fire extinguishing systems. The fire water would be supplied from up to ten on-site wells and stored in two 800,000-gallon water storage tanks (one at each power block) with a dedicated fire protection supply of 600,000 gallons in each power block and 480,000 gallons in a storage tank in the common area (Palen 2012a). One primary electric and one diesel-fueled backup firewater pump would ensure water supply to each fire protection loop at a maximum flow of 5000 gpm (Palen 2012a).

Fire hydrants would be installed throughout the site per NFPA requirements and a sprinkler deluge system would be installed in areas of risk including each unit's transformer. A sprinkler system would be installed at the steam turbine generators (STGs), in the towers, and in administrative buildings (Palen 2012a). In addition to the fixed fire protection system, appropriate class of service portable extinguishers and fire hydrants/hose stations would be located throughout the facility at code-approved intervals.

According to NFPA standards and Uniform Fire Code (UFC) requirements, the fire protection system must have fire detection sensors and monitoring equipment that would trigger alarms and automatically actuate the suppression systems. Staff has determined that these systems will ensure adequate fire protection.

The project owner would be required by Conditions of Certification **WORKER SAFETY-1** and **-2** to provide the final Fire Protection and Prevention Program to staff and to the RCFD prior to construction and operation of the project to confirm the adequacy of the proposed fire protection measures.

The major issue in contention regarding fire protection at this proposed solar power plant is the level of mitigation required to reduce the direct impacts to the RCFD to a level of insignificance. The petitioner, RCFD, and staff have all spent a considerable amount of time and effort reviewing this issue and explaining their respective positions. Despite these efforts and agreement that direct impacts would occur, no agreement among the parties has been achieved regarding the level of mitigation required and thus staff has undertaken a comprehensive review and evaluation of the impacts to the RCFD and arrived at a recommended level of mitigation.

Staff has considered the position of the RCFD and all relevant information as well as past experience at existing solar power plants that are similar to the proposed modified project. The proposed facility would be located in an area that is currently served by the RCFD. The fire, HazMat, rescue, inspection, and EMS needs at the proposed plant are real and would pose significant added demands on local fire protection services. In addition, staff concludes that the RCFD's Hazmat Response Team is not adequately equipped and staffed to respond to hazardous materials incidents at the proposed facility with an adequate response time. Staff concurs with the past and current assessment of the RCFD regarding direct impacts and has determined that the PSEGS would cause a significant direct impact on the local fire department but not cause a significant cumulative impact. A direct impact is caused by the need to equip and train the fire department to respond to the specific unique hazards posed by solar tower technology which would be new to the county. No significant cumulative impact would occur because the construction and operation of this solar power plant is not likely to change the overall hazard profile of facilities requiring emergency response in the county, emergency events at this solar power plant are not likely to escalate within or beyond the power plant site, and emergencies are not likely to occur simultaneously with other facilities.

Staff concludes that the RCFD will have to provide some level of services and encumber significant time and funds in six areas:

1. Becoming familiar with and planning for emergency responses to a facility using a solar energy technology new to Riverside County.

2. Plan reviews and inspections..

3. Fire response.

4. Hazmat spill response.

5. Rescue.

6. Emergency Medical Services (EMS).

Because there are no thermal solar power plants currently operating within the jurisdiction of the RCFD (one parabolic trough solar project, the Genesis Solar Energy Project, is expected to begin commercial operations in the Fall 2013), staff reviewed incidents involving solar power plants in San Bernardino County, including the newly built segments of the Ivanpah Solar Electric Generating System that uses solar tower technology. In summary, staff found that including emergency response for fire, rescue, medical and hazardous materials incidents, approximately 30 incidents occurred since 1998 that required the San Bernardino County Fire Department (and other fire stations through mutual aid agreements) to respond to four solar power plant sites currently operating within San Bernardino County. These included fires, fire alarm activations, injuries, medical emergencies, hazardous materials spills, complaints/calls from the public, and false alarms. However, the available records did not include documentation of a major fire at the SEGS 8 facility (80 MW) in January of 1990 that required a large part of the regional resources from four different fire districts including the San Bernardino County, Edwards Air Force Base, California Department of Forestry (now Cal Fire), and the Kern County fire departments. This fire is the largest incident that has occurred at a solar thermal plant in California and demonstrates the magnitude of fire department resources that can be required to respond to a fire at a large thermal solar facility. The inability to quickly control this event had ramifications for the project's finances and reliability - it took almost two years to bring the SEGS 8 heaters back on-line and supplement the solar field generation – and resulted in a "draw-down" of emergency response resources in the northern part of San Bernardino County. A "draw-down" is when emergency response teams vacate an area to respond to an emergency, thus leaving that area without adequate fire and other emergency response services. This represents a very serious situation where the population and infrastructure is left vulnerable.

The proposed PSEGS is very different from the industrial, commercial, and residential development currently found in the Riverside County desert region. It is also different from the existing solar plants located at Harper Lake and Kramer Junction in San Bernardino County. The PSEGS would consist of two towers, 750-feet high that would be similar to the solar towers being built and presently under commissioning at the Ivanpah project. The towers would present a much greater challenge for rescue than the original, mostly ground-level, PSPP project and present a greater challenge to fight a fire at the high elevations of the tower.

Presently, staff believes that the RCFD would able to respond to fire, hazmat, and EMS emergencies in a timely manner at the PSEGS, but not to high angle technical rescue emergencies. The standard fire department response for a fire or for a hazmat spill includes response of six engines and at least three fire fighters on each engine. To fight a fire inside a structure, the RCFD must adhere to standard operating procedures and Cal-OSHA regulations that require “two in, two out”. Thus, a response of three fire fighters from one station would not allow fire fighters to attack a fire from within a structure or conduct a rescue. Confined space and collapsed trench rescues would also be problematic with only three fire fighters. Therefore, no matter what size the fire or how many workers are initially in need of rescue, the RCFD would dispatch engines from at least three fire stations so that at a minimum, nine firefighters are sent to the scene but the RCFD could eventually dispatch a total of 9 engines. Even if mutual aid was available and an “automatic aid” pact was in effect (which as of the date of the FSA there are none in effect), the RCFD would still have to respond to an emergency at the PSEGS site because it is the Authority Having Jurisdiction. Additionally, it is very important to note that the PSEGS will be located in an extremely harsh desert environment. The ability of a fire fighter to perform duties while wearing a turn-out coat, heavy boots, and a respirator (self contained breathing apparatus) is limited under the best of circumstances. If conducting a rescue or fighting a fire that necessitates use of a respirator, the high-temperatures of the desert, often exceed 115°F, severely limits a fire fighter’s ability to perform the duties to 15 minutes at a time. This severe time restriction necessitates the mobilization of more fire fighters to respond to the emergency. Therefore, there exists ample evidence of a significant direct impact on the RCFD.

In order to assist in determining proper mitigation for significant impacts, staff has developed an Emergency Response Matrix that staff, the fire departments, and project owners may use to assess the level of emergency response need (CEC 201o). This analytical tool has a weighting scheme for the various categories of fire department response and utilizes professional judgment in the assignment of the “score” to the categories. Staff has tested this methodology on existing and planned solar power plants and concludes it to be useful but cautions against using it as the <u>sole</u> basis for determining need or for allocating financial responsibility for direct individual or cumulative impacts. Otherwise, staff recommends that the project owner prepare an independent fire needs assessment and a fire risk assessment for the Palen project to better assess impacts on emergency response services in the jurisdictions.

Staff's analysis and determination of mitigation is based upon the following:

1. A revised Staff Emergency Response Matrix(CEC 2013k; see **Worker Safety/Fire Protection Appendix A**);
2. The recent events at the Ivanpah Solar Energy Project which utilizes solar tower technology;
3. The increased need for and difficulty of rescue in a tower;
4. The need for the RCFD to expend resources to become familiar with new technology within its jurisdiction;
5. The decreased fire risk due to the removal of HTF and propane from the project;
6. The decreased risk of explosion due to the removal of propane; and
7. Staff's expertise and judgment.

Although the modified project will undoubtedly lower the risks of certain impacts, other risks would be raised. The original PSPP project is required by the Decision to pay to the RCFD as mitigation of both direct and cumulative impacts a total of $12,100,000 over a 30-year project lifespan ($850,000 initially for capital improvements and $375,000 annually for operations and maintenance). This amount was determined by staff when considering the impacts of the three solar projects proposed for the I-10 corridor within Riverside County that included the Genesis project and when considering that the PSPP was going to use HTF in a parabolic trough solar power plant.

The petitioner has provided a Fire and Emergency Services Risk Assessment (FESRA; Palen 2013ll) that staff has reviewed. The stated scope of this FESRA was to "review the potential for hazards to occur" during construction and operation of the PSEGS and "define the risks that would require fire protection and emergency medical services". An implied but not stated part of the scope was to recommend mitigation in the form of payments to the RCFD.

Staff had requested that a "Fire Needs Assessment" and a "Risk Assessment" both be prepared if the petitioner wished to make a case for a reduction in the amount of funds required for mitigation in the Decision. As discussed in the section entitled "Methodology and Thresholds for Determining Environmental Consequences" above, staff had previously established a procedure where a project owner can either accept the determination made by staff or refute the determination by providing a Fire Needs Assessment and a Risk Assessment. The Fire Needs Assessment would address fire response and equipment, staffing, and location needs while the Risk Assessment would be used to establish that while an impact to the fire department may indeed exist, the risk (chances) of that impact occurring and causing injury or death is less than significant.

In this case, the Energy Commission in its Decision has determined the amount of payments necessary and proper to fund fire and emergency services as mitigation for both direct and cumulative impacts. That amount, which is required by current Condition of Certification **WORKER SAFETY-7,** would amount to $12,100,000 dollars over a 30-year facility life-time. When the current petitioner (Palen Solar Holdings LLC) purchased the approved Palen project, they also purchased all encumbrances and responsibilities including the requirement to pay all amounts required by the Conditions of Certification.

However, staff is very much aware that things do change and has made an effort to provide some relief to the petitioner based upon what staff believes is a fair and objective metric and in consideration that a significant cumulative impact no longer exists because of the change in technology from parabolic tough utilizing HTF to a solar tower with heliostats. Staff recommended in the PSA that, in considering all the information available and taking the ratio of the new scores obtained for the modified PSEGS (2.4) vs. the present Genesis project (2.8) obtained by utilizing the revised Emergency Response Matrix and applying that ratio (0.86) to the $12,100,000 required by the Commission Decision, the result is a small reduction to ~$10,400,000 over thirty years and that would be the proper revised amount as mitigation to be paid by PSEGS.

In reviewing the new information contained in the FESRA provided by the petitioner, staff found that the report provided some useful information and perspective, despite containing a number of flaws. Staff notes that the report contains some assertions of probabilities unsupported by data or references, has no analysis of recent incidences at a similar solar tower in California (Ivanpah), and fails to provide a more robust economic analysis found in most fire service needs assessments, including the one prepared for the Abengoa Mojave Solar Project in 2012 (BAE 2012) that addressed the issue of facility exemption from property taxes, and the one in 2011 addressing U.S. fire service needs (NFPA 2011).

Specifically, staff found the following sections of the report to be either useful, lacking in substantive explanatory discussion, stating a position with which staff disagrees, or stating a position with which staff agrees.

- Section 2.2.11 Fire Protection System: This section contains a comprehensive description of fire systems at the PSEGS.
- Section 3.0 Applicable Standards contains a comprehensive discussion of LORS.
- Section 4.0 Fire Protection System: There is no discussion of any fire detection or suppression systems for the towers or lack thereof until a brief few words in Appendix A which did not include any discussion, elaboration, or detail.
- Section 6.0 Hazards of the Project contains a useful discussion of all hazards during construction and operations except those sections noted below.

- Section 6.4, Table 6-5 (Risk Probability at PSEGS): Although briefly discussed in the narrative on page 6-9 and purportedly based upon Cal-OSHA, National Fire Incident Reporting System (NFIRS), and California State Fire Marshall (CSFM) data (references not provided in the report), this table lacks any detailed explanation for the assigned risk probabilities of “Remote” and “Improbable” for many worker safety hazards. The probabilities appear to be based more on professional opinion rather than an analytical quantitative approach. Staff has considerable experience in occupational safety and health and in power plant OSHA matters and strongly disagrees with the assigned probabilities. Staff believes that the probabilities of hazards resulting in worker injuries at solar power plants under construction is actually very likely (almost a certainty) and not remote or improbable. Staff believes that the argument made in the report – that there is little, if any, chance that an event would occur at the proposed PSEGS, and that fire and emergency services would rarely, if ever, be needed – even if accurate is not an acceptable approach to fire protection and emergency response. Fire departments must plan for the possible, not the probable, and staff believes that unless the chances of an event are so remote as to be beyond the scope of reality, the fire department must plan for those events. Determining mitigation payments based upon an estimated future use is not appropriate fire protection. Even if the need for high angle rescue occurred only once in 30 years, staff is confident that the life of that one worker is worth the investment in rescue ability. Most homeowners and business owners never have the need for fire or emergency services in their lifetime and yet all pay for those services regardless of use. The fact that a solar tower environment is inherently risky and that smoke events have already occurred in the towers at Ivanpah convinces staff that the probabilities listed in Table 6-5 are inaccurate.
- Section 7.0 Existing Resources provided useful information about the RCFD and service call history.
- Section 8.1.1 Fire Protection: There appears to be no basis for stating risks requiring fire protection and EMS during construction and operation would be “extremely low”. No attempt was made to examine the fire, rescue, and EMS needs at existing solar power plants in the world or in California. For example, staff has reviewed the need for fire response at the Ivanpah solar power plant under construction and notes that the San Bernardino County Fire Department has responded to 3 incidences of fire or smoke events during the past 2 and ½ years of construction.
- Section 8.1.2 Technical Rescue: The report categorizes the demand for technical rescue (defined by the NFPA as including rope rescue, swiftwater rescue, confined space rescue, ski rescue, cave rescue, trench/excavation rescue, building collapse rescue, and high angle rescue) as being “extremely low”. The report appears to provide no basis for this assertion and provided little or no empirical evidence or data. Staff disagrees that the probability is “extremely low” and believes that rescue from a tower is not improbable. Besides, a fundamental duty of any fire department is to prepare for any reasonably foreseeable event and the need for rescue or evacuation from an enclosed 750-ft. tower which will contain high pressure and temperature steam piping systems that require ongoing maintenance both inside and outside the tower near the 750-ft. level is most definitely foreseeable and, quite frankly, likely to be needed.

- Section 8.1.2 Technical Rescue: The statement in the last sentence at the bottom of page 8-2 is incorrect. Currently there is no mutual aid contract with the Blythe Fire Department.
- Section 9.0 Recommendations: The report claims that workers at the towers will be trained based on “federal and state standards and equipment manufacturers’ requirements”. Other than generic federal and state OSHA standards, no citation has been provide for any safety standard specific to solar tower workers or to manufacturer’s requirements.
- Section 9.0 Recommendations: This section also contains recommendations for mitigation with which staff disagrees. The analysis appeared to minimize the need for fire and emergency services thus resulting in a level of mitigation inconsistent with staff’s analysis and findings.
- Appendix A: PSEGS Fire Protection Design Basis provided some information about the towers not before presented by the petitioner and therefore was both informative and useful.

The County of Riverside (CR) and the RCFD (CR 2013c**)** provided its assessment of the FESRA and staff has reviewed their comments. In summary, the CR/RCFD takes issue with some of the content and conclusions of the FESRA, what it feels to be a downplaying and minimization of the possible severity and frequency of occurrence of any potential impacts to the RCFD, the amount of mitigation to be provided, and the attempt to demonstrate that, based on call volume, no additional RCFD staff would be needed as a result of this Project (Paragraph 2, Page 7-5).

Specifically, staff found the following sections of CR/RCFD’s review of the FESRA to be on some points useful, lacking in substantive explanatory discussion, stating a position with which staff disagrees, or stating a position with which staff agrees.

- P. 1, 2: CR takes issue with some of the content and conclusions of the FESRA, the attempt to downplay and minimize the possible severity and frequency of occurrence of any potential impacts to the RCFD. – Staff agrees with this position.
- P. 1, 2, and 3: CR takes issue with Table 6-4 of the FESRA, the use of subjective adjectives in the “Description” column to quantify the frequency of occurrence for possible incidents, and the appearance that descriptions were chosen to create an image of little to no possibility that such an incident will occur. – Staff agrees with the CR position and has explained its criticism of Table 6-4 in comments above.
- P. 3, 1: CR takes issue with the FESRA attempt to use call volume, to support its contention that no additional RCFD staff would be needed as a result of this Project. RCFD has not claimed a significant call demand would occur; it is the various hazards created by this Project and the types of inherent risks associated with potential emergencies which will impact the County. RCFD categorizes these as low *frequency/high risk/little discretionary time* emergencies. The most significant impact to RCFD is the need to be prepared to provide immediate Technical Rescue services, which has normally been necessary only in built up commercial/industrial areas of the County. This is a significant increase in the service level from the basic service level historically provided to this otherwise rural desert area. – Staff agrees with this position and has articulated it above on page 4.14-28.

- P. 3, 2: CR believes that industrial accidents still occur in spite of all the LORS and that even basic medical emergencies can create access and rescue challenges when such emergencies occur high on catwalks or inside piping, tanks, vaults, or within a tower. – Staff agrees and while not wanting to downplay these risks, does not want to exaggerate them either. As staff has stated above (p. 4.14-6) and in the analysis of all power plants, industrial environments are potentially dangerous during construction and operation of facilities.
- P. 3, 3: CR states that it hopes that the RCFD would never need to respond to this facility but it is not realistic to base emergency preparedness on such hopes. The RCFD will need to be prepared to provide Technical Rescue services in addition to fire response as a result of the development of power plant. – Staff agrees and once again reiterates that it believes that fire departments must plan for and be cable of responding to all reasonably anticipated emergency scenarios.
- P. 3, 4: CR feels that the FESRA minimally addresses technical rescue in Section 8.1.2 and strongly disagrees with the conclusion. - Staff shares this view and has articulated in concerns above on page 4.14-29.
- P. 3, 6: CR explains that RCFD is the official "Authority Having Jurisdiction" for emergency responses to the project and disagrees with the suggestion that mutual aid might be used to help mitigate primary fire services for this project. CR goes on to explain that providing mutual aid is voluntary, not required, and is dependent on the availability of the provider's fire resources during any particular emergency. Mutual aid, therefore, is generally not depended on for primary service delivery. – Staff agrees with this position and has stated similar views on pages 4.14-4 and 4.14-29 above.
- P. 3, 7: CR states that The California Mutual Aid Plan clearly articulates that a jurisdiction is not required to respond outside their jurisdiction based on its own activities and needs, and further provides "… that no party shall be required to unreasonably deplete its own resources in furnishing mutual aid." While the County fully believes the Blythe City Fire Department would make every effort to assist RCFD at the project, it is not appropriate to assume Blythe City Fire Department would always be available, based on their own responsibility to respond first to incidents within their own jurisdiction. – Staff concurs with this interpretation of mutual aid in California.
- P. 4, 2: CR states that each jurisdiction relies first upon its own resources and thus has a responsibility to plan for these emergencies through proper training, equipping and staffing. It is inappropriate to burden, and potentially overextend, the Blythe City Fire Department in a first response capacity within the County's jurisdiction in lieu of appropriately staffing, training and outfitting RCFD resources. – Staff concurs and finds that this approach is consistent with its understanding of basic emergency planning.

- P. 4, 5: Section 2.2.3 access roads: The County wants all fire access road to meet RCFD Standards. – Staff agrees and towards that proposes three requirements in Conditions of Certification: 1), all roads must be capable of supporting fire engines that weight up to 60,000 pounds; 2) the Construction Fire Prevention Plan required by proposed Condition **WORKER SAFETY-1** must be submitted to the RCFD for review and comment, and 3),) the Operations Fire Prevention Plan required by proposed Condition **WORKER SAFETY-2** must also be submitted to the RCFD for review and comment.
- P. 4, 6: Section 2.2.11: CR notes that the reference to the Indio Office of the Riverside County Fire Department is incorrect. – Staff notes this.
- P. 4, 7: Section 2.2.11: CR notes that the references to Riverside County Ordinance No. 787.1 are outdated and that the correct reference is Ordinance No. 787.6. – Staff notes this.
- P. 4, 8: Section 3.2: CR notes that while the Uniform Fire Code, Article 80, is listed as a National Consensus Standard, the applicable code for this project will be the 2010 California Fire Code Chapter 27. – Staff agrees and had already noted this in **Worker Safety and Fire Protection Table 1** Laws, Ordinances, Regulations, and Standards (LORS) found on page 4.14-3&4 of this section.
- P. 4, 9: Section 3.3: Riverside County Fire Protection and Medical Master Plan - 1987. CR notes that this document is referenced in the FESRA several times yet was not discussed with RCFD during the development of the FESRA. The 1987 Master Plan is in the process of being replaced. A draft companion “Strategic Master Plan” has been completed and is in final editing, and will finalize the replacement of the 1987 Master Plan document. This is anticipated to be finalized prior to the Project’s approval. – Staff thanks the CR for this update.
- P. 4, 10: Section 8.1.3: CR disagrees with the statement in the FESRA that “addition of the PSEGS to the RCFD service area would not require additional emergency medical responses from the RCFD.” Any private duty industrial health care provider would not supersede the authority of, and has less capability than, RCFD paramedics operating within EMS control. Although an onsite nurse would be practical in an occupational health and safety situation, an onsite nurse is not recognized as a pre-hospital provider within the Riverside County EMS system. – Staff concurs and believes that any on-site provision of emergency response would be in addition to, not instead of, EMS response from the RCFD.

- P. 5, 2: Section 8.2: CR disagrees with the contention that the project can eliminate the need for emergency medical services and takes exception to paragraph 5 of this section wherein the applicant attempts to further deflect mitigation by introducing the argument that added resources would “primarily be used for incidents involving the general population…” and “…provide a net benefit to Riverside County.” It must be remembered that impacts on the County and requested mitigations are a direct and proximate result of the construction of major solar thermal power plants, including this project. Absent the construction of these significant industrial projects, impacts on the County and consequent need for mitigation would be substantially reduced. Riverside County is not seeking a net benefit from these facilities, but must respectfully demand that RCFD’s necessary capital and operational costs of emergency preparedness resulting from this Project be mitigated. – Staff agrees with this criticism of the FESRA and believes that ample evidence exists, as discussed above, that a direct significant impact on the RCFD is posed by the project that must be mitigated. This includes all types of services as listed above on page 4.14-24.
- Staff also wishes to point out that CR has not commented on the change in technology from parabolic trough using HTF to solar tower described in the FESRA in Sections 2.1 and 6.1. This change will result in a greatly reduced hazard posed by HTF and propane and was not been adequately discussed in the assessment by the County. This greatly diminished risk should not go overlooked and staff has noted this factor several times in the PSA and in this FSA. It is on this point, and the contribution this lowered risk makes to the impacts on the RCFD, that most likely serves as the basis for the difference in mitigation requested by staff and the County.

Riverside County also presented information and opinion on fire needs and mitigation from the RCFD in a comment letter on the PSA (CR 2013a). Several points made by CR under **Worker Safety & Fire Protection**, beginning on page 10 of that letter include:

> P. 10, 2: The County acknowledges that the change in technology reduces the presence of flammable products on-site but there still remain significant potential site hazards, worker safety risks, numerous sources of potential fire and explosions, medical emergencies, and technical rescues. -- Staff agrees that potential significant fire and safety risks would exist with the modified project but not that they would be numerous.
>
> P. 10, 3: In many respects, a number of these significant risks and hazards and any response to them are actually greater under the proposed tower technology than under the previously approved trough technology, and these greater risks and hazards off-set the reduction in risk attributable to the removal of flammable products. -- Staff disagrees with CR on this point and believes that in total, the risks and hazards are less with the modified project.

P. 10, 4: The RCFD must prepare for more complex emergencies requiring technical expertise and specialized equipment including, but not limited to, confined space, trench, hi-angle rope rescues, entrapments, etc. -- Staff agrees only with the need to prepare for high angle technical rescue. Staff believes that the need for confined space rescue would be less with the modified project and trench, entrapment, and medical emergencies would also be less or about the same. RC has not presented any data or professional experience to support its claim.

P. 11, 1: This also may include medical emergencies which occur in restricted access locations in and around the power block or within the towers.-- Staff believes that the need for response to medical emergencies would not be increased for the power block but would be increased for emergencies within the tower.

P. 11, 3: The RCFD will have an immediate and urgent need to rapidly ramp up a significantly greater level of planning, staffing, equipping, training, housing, and overall preparedness for responding to these potential and likely emergencies before major construction activity begins on the project. -- Staff agrees in part that there will be an immediate need to plan, staff, and train for the specific unique fire and safety risks posed by the construction and operations of the towers but not for the power blocks or heliostat arrays.

P. 11, 3: It will be necessary to configure and prepare RCFD Battalion 8 to respond to the PSEGS and Genesis projects and therefore there will be a significant impact on the County's emergency services which must be mitigated. -- Staff agrees and Genesis is already mitigating its direct and cumulative impact and staff proposes that PSEGS mitigate its direct impact.

P. 11, 4: In 2010, it was determined by the CEC that the impacts to RCFD must be fully mitigated and mitigations were crafted to be spread out over four solar thermal projects. In reality, there is now one project underway that is contributing (Genesis), and this project (Palen) in which there is a request to reduce their participation in our mitigation. As of the date of this letter, the other two solar thermal projects, Blythe and Rice, have not moved forward. The County does not have the ability to go back and re-condition Genesis for a larger participation level. -- Staff understands this issue and is sympathetic to the complexities and difficulties of planning for fire and emergency response in a constantly changing environment. But CEQA dictates that staff proposes mitigation for direct impacts from only those projects that are actually built and proposes additional mitigation for cumulative impacts when such impacts exist. In this case, staff must address the impacts of the project as it is currently modified and while staff has found that direct impacts would exist, it has determined that no cumulative impact would exist. As a factual matter, Rice is scheduled to break ground in March 2014 and Blythe has a modification before the Commission which if granted would result in some level of mitigation, albeit a reduced level.

P. 11, 5: This leaves Riverside County with still having a need to increase our fire and emergency service level in order to serve PSEGS and Genesis, and a significant lack of mitigating funds in order to cover our costs to do so. – Staff differs with this contention and believes that the mitigation already required and paid by the Genesis project and that proposed by staff would be adequate to mitigate the direct impacts of both projects and the cumulative impacts of the Genesis project.

P. 11, 5: It is therefore crucial that fire mitigation not be decreased as proposed by PSH, but instead at minimum, the previous level of mitigation conditioned for the project is maintained – commensurate with the mitigation currently paid by the Genesis project. – Staff understands the rationale for this request but differs on the amount of mitigation. However, staff notes that with the staff recommended annual escalator (requested by the RCFD), the total received by the RCFD for mitigation from PSEGS would be greater over the life of the project than the amount now required by the decision.

The County also provided additional comments specifically on the PSA which are discussed and responded to in the section **RESPONSE TO COMMENTS** below.

Staff finds that both the RCFD and the petitioner have raised some valid issues and important points in their comments and both also neglected to discuss certain variables that staff believes should be a factor in determining impacts and hence mitigation.

Although staff has differences of opinion with both the petitioner’s Fire and Emergency Services Risk Assessment and the position of the RCFD as outlined above, staff finds that the arguments made by the County of Riverside to be more compelling and better documented. Differences of professional opinion also exist between the petitioner and the RCFD and thus staff must make a recommendation without the benefit of a consensus among the parties. Staff finds that the Fire and Emergency Services Risk Assessment did not provide compelling evidence or arguments to serve as a basis for staff to modify its recommendation for funds to mitigate direct impacts to the RCFD.

Staff therefore continues to propose a one-time payment of $1.0 M for capital improvements and an annual payment of $313,000 for O&M for the remaining lifetime of the power plant as mitigation for direct impacts. Staff also believes that the RCFD raised an important point when it requested that the annual payments for mitigation include a cost-of-living escalator. Staff agrees and has added this to proposed revised Condition of Certification **WORKER SAFETY-7.** Staff proposes that the Consumer Price Index (CPI-U, US City Average, All Items Less Food and Energy) for the previous calendar year as published by the U.S Bureau of Labor Statistics be used as the annual escalator to account of inflation. The following table shows the different amounts proposed for mitigation:

Worker Safety and Fire Protection Table 6
Proposed Mitigation

	Decision	Staff proposed in PSA	Staff proposed in FSA	Petitioner	RCFD
one-time payment for capital improvements	$850,000	$1,000,000	$1,000,000	$1,200,000 (for a medium rescue vehicle)	$850,000
annual first 3 yrs	$375,000	$313,333	$313,000	$684,000	$375,000
annual yrs 4 - 30	$375,000	$313,333	$313,000	$114,000	$375,000
annual escalator	None	none	CPI-U	none	requested
Total over 30 yrs	$12,100,000	$10,400,000	$13,700,000*	$6,330,000**	$16,000,000

* at an average of 2% increase/yr, total over 30 yrs = $13.7 M (the average yearly increase in the CPI-U excluding food and energy in the past 10 years is ~2.1%)
** with 2% annual increase, total over 30 years would be ~$7.32M
*** with 2% escalator

Staff is recommending that both the initial one-time payment and the first annual payment be made no later than 30 days prior to the start of site mobilization because the fire department needs as much lead time as possible to procure equipment, adjust staffing needs, become familiar with the exact layout of the project, and conduct training.

Also, because of a few problems at other solar and gas-fired power plants where questions about fire department plan review and inspections have been raised, staff believes that it is necessary to clearly define the duty of the project owner to work with the local fire department in the review of fire detection and suppression systems. Staff therefore recommends adoption of new condition of Certification **WORKER SAFETY-10** which would require the project owner to submit to the RCFD all plans and schematic diagrams that show the details of all fire detection and suppression systems and pay the RCFD its usual and customary fee for the review of those plans and for inspections to ensure compliance with those plans. The project owner would then be required to provide proof to the CPM that the plans have been submitted to the RCFD on a timely basis, a copy of the comments received from the RCFD, and proof that the usual and customary payments for plan review have been made to the fire department.

EMERGENCY MEDICAL SERVICES RESPONSE

Staff conducted a statewide survey to determine the frequency of Emergency Medical Services (EMS) response for natural gas-fired power plants in California. The purpose of the analysis was to determine what impact, if any, power plants may have on local emergency services. Staff concluded that incidents at gas-fired power plants that require EMS response are infrequent and represent an insignificant impact on the local fire departments, except for instances where response times are high or a rural fire department has mostly volunteer fire-fighting staff. However, staff has determined that the potential for both work-related and non-work-related heart attacks exists at power plants. In fact, staff's research on the frequency of EMS response to gas-fired power plants shows that many of the responses for cardiac emergencies involved non-work-related incidences, including those involving visitors. The need for prompt response within a few minutes is well documented in the medical literature. Staff believes that the quickest medical intervention can only be achieved with the use of an on-site automatic external defibrillator (AED); the response from an off-site provider would take longer regardless of the provider location. This fact is also well documented and serves as the basis for many private and public locations (e.g., airports, factories, government buildings) maintaining on-site cardiac defibrillation devices. Therefore, staff concludes that, with the advent of modern cost-effective cardiac defibrillation devices, it is proper in a power plant environment to maintain such a device and the trained staff on-site in order to treat cardiac arrhythmias resulting from industrial accidents or other non-work related causes.

Existing Condition of Certification **WORKER SAFETY-5,** requires that a portable AED be located on-site, that all power plant employees on-site during operations be trained in its use, and that a representative number of workers on-site during construction and commissioning also be trained in its use. Comments from the RCFD include the suggestion that condition **WORKER SAFETY-5** also include a requirement that workers on-site be trained in basic first aid and that basic first aid kits be available on-site. Staff agrees with these suggestions and thereof proposes changes to this condition to include these requirements.

Also, at the request of the Riverside County Airport Land Use Commission, who raised a concern about the safety of medevac helicopters flying into or landing in an area where a thermal plume would exist (CR 2013b), a revision to Conditions of Certification **WORKER SAFETY-1** and **WORKER SAFETY-2** is proposed by staff to include a requirement that the project owner submit an Emergency Medical Evacuation Plan as part of the Emergency Response Plan, one for the construction period and another for operations. Staff does not anticipate emergency medical helicopters landing within the heliostat fields due to space constraints; instead, emergency medical helicopters would likely land at the perimeter of the facility, or in the common area. Thus, staff believes that no helicopters would be at risk from a thermal plume at the site. The requirement that an Emergency Medical Evacuation be prepared and submitted to the Compliance Project Manager (CPM) for review and approval would ensure that the helicopters are not placed at risk.

NON-OPERATION AND FACILITY CLOSURE IMPACTS AND MITIGATION

Closure of the proposed PSEGS (temporary or permanent) would follow a facility closure plan prepared by the project owner and designed to minimize public health and environmental impacts. Non-operation and facility closure procedures would be consistent with all applicable LORS (Solar Millennium 2009a, Section 5.6.3.4). Staff expects that impacts from non-operation and facility closure process would represent a fraction of the impacts associated with the construction or operation of the proposed PSEGS. Therefore based on staff's analysis for the construction and operation phases of this project, staff concludes that worker safety and fire protection-related impacts from non-operation and closure of the PSEGS would be insignificant.

Red Bluff Substation

The SCE Red Bluff Substation is expected to be operational in December, 2013. Therefore, staff concludes that there won't be any overlap of construction phase of SCE Red Bluff Substation and the PSEGS. Therefore, there is no need to discuss the potential impacts of the construction of the SCE Red Bluff Substation.

Conclusion

Incorporation of the measures discussed above and the Conditions of Certification recommended for the PSEGS would ensure adequate levels of industrial safety and fire protection and would comply with applicable LORS.

CUMULATIVE IMPACTS

The **Executive Summary** provides detailed information on the potential cumulative solar and other development projects in the project area. Together, these projects comprise the cumulative scenario which forms the basis of the cumulative impact analysis for the proposed modified project. In summary, these projects are placed into three categories:

- Existing energy projects on BLM, State, and private lands: Four projects are listed in **Executive Summary Attachment A – Table 1**.
- Foreseeable future energy projects in the immediate area and in the desert region: Thirty-eight foreseeable projects are listed in **Executive Summary Attachment A – Table 2**.
- Existing and foreseeable non-energy projects on BLM, State, and private lands: One hundred and nine projects are listed identified in **Executive Summary Attachment A – Tables 1** and **2**.

All of the above projects are defined within a geographic area that has been identified by the Energy Commission as covering an area large enough to provide a reasonable basis for evaluating cumulative impacts for all resource elements or environmental parameters. Most of these projects have, are, or will be required to undergo their own independent environmental review under the California Environmental Quality Act (CEQA). Even if the cumulative projects listed in the **Executive Summary Attachment A** tables have not yet completed the required environmental processes, they were considered in the cumulative impacts analyses in this section.

EFFECTS OF PAST AND PRESENT PROJECTS

For this analysis, staff notes that all of these projects or developments in the area or region have or will need the plan review and emergency response services of the RCFD. And, staff has found that when combined with the proposed PSEGS, all would not have a cumulative impact on the region. The need for rescue, fire, hazardous materials, and EMS response is frequent, yet not concentrated in this county because the distances between the projects are very great. Area power plants that are operating, under construction, or proposed p have had any direct fire protection impacts mitigated to a level of less than significance.

Staff has analyzed the potential for fire protection cumulative impacts at many other power plant projects located in California and in the region of the proposed PSEGS. A significant cumulative fire protection impact is defined as the simultaneous emergency at multiple locations that would require the concurrent response for rescue, fire fighting, hazardous materials spill control, and/or EMS response. Existing locations that would likely need emergency response, or locations where such facilities might likely be built, were both considered.

Staff believes that while cumulative impacts are theoretically possible, they are not probable because of the many safeguards implemented to both prevent and control the work environment, spills, and fires. The chances of one event requiring a concerted response from the RCFD is high because accidents do happen at industrial environments. However, the chance of two or more occurring simultaneously, with resulting draw-down of fire department resources to the point of endangering other communities with lack of fire department coverage are real but not as great. Staff believes the risk of draw-down due to an event at the proposed PSEGS is less than significant and thus the mitigation proposed in revised Condition of Certification **WORKER SAFETY-7** would address a direct individual impact and reduce it to a less than significant impact.

The project owner will develop and implement a fire protection program for the PSEGS independent of any other projects considered for potential cumulative impacts. Staff believes that the facility, as proposed by the project owner and with the additional mitigation measures proposed by staff, poses a less than significant risk.

Contribution of the Palen Solar Electric Generating System to Cumulative Impacts

Construction. The construction of PSEGS is not expected to result in short term adverse impacts related to fire protection during construction activities. It is expected that some of the cumulative projects described above which are not yet built may be under construction the same time as the PSEGS, however, short term impacts related to fire protection during construction of those cumulative projects are not expected to occur.

Operation. The operation of the PSEGS is expected to result in long term adverse impacts during operation of the project related to fire protection and staff has recommended mitigation in the form of Condition of Certification **WORKER SAFETY-7** to reduce that impact to a less than significant level.

Non-operation and Facility Closure. The non-operation and facility closure of the PSEGS is not expected to result in adverse impacts related to fire protection similar to construction impacts. It is unlikely that the construction or facility closure of any of the cumulative projects would occur concurrently with the facility closure of this project, because the facility closure is not expected to occur for approximately 30 years. As a result, it is not expected that significant impacts related to fire protection during facility closure of the PSEGS generated by the cumulative projects will occur.

COMPLIANCE WITH LORS

Staff concludes that construction and operation of the PSEGS project with staff's proposed mitigation would be in compliance with all applicable laws, ordinances, regulations, and standards (LORS) regarding long-term and short-term project impacts in the area of worker safety and fire protection.

NOTEWORTHY PUBLIC BENEFITS

Staff is unable to describe any noteworthy pubic benefit in the area of Worker Safety and Fire Protection.

RESPONSE TO COMMENTS

Staff has received numerous comments on fire protection issues consisting of opinions, suggestions, technical information, and factual rebuttal of other parties' comments as well as general comments on the contents of the PSA. Technical information and those comments staff considers to be more of a factual rebuttal of other technical information are described and responded to within the section on Fire Protection beginning above on page 4.14-24.

PSA WORKSHOP ON JULY 17, 2013:

The RCFD made the following verbal comments and suggestions:

Comment: The RCFD had no issues with existing Conditions of Certification **WORKER SAFETY-1** through **4.**

Response: *Thank you*.

Comment: Regarding existing Condition of Certification **WORKER SAFETY-5**, the RCFD suggested that the workers be trained in the operations of an AED and that they also be trained in basic first aid and have basic first aid kits available on-site.

Response: *Training on AEDs is already required in this condition and staff agrees that training in first aid should be required and has been proposed that it be added to this Condition.*

Comment: Regarding revised Condition of Certification **WORKER SAFETY-6**, the RCFD agreed with the wording but voiced a concern that any desert dirt access road be capable of supporting a 60,000 pound fire truck.

Response: *Comment noted and the Petitioner has noted it as well and assured the fire department that the access road and all roads within the facility would be capable of supporting any fire truck. Towards that, staff has proposed a requirement in Condition of Certification **WORKER SAFETY-6.***

Comment: Regarding revised Condition of Certification **WORKER SAFETY-7**, the RCFD disagreed with staff's recommended mitigation, stated that the impacts to the fire department did not decrease with a change in technology, and suggested that staff consider a cost-of-living or other inflation adjustment for the annual payments as the amount proposed would be greatly diminished by inflation over a thirty-year lifespan of the project.

Response: *Staff agrees that a cost-of-living or other escalator metric be used to increase the annual payment over the life of the project and has added that to Condition of Certification* ***WORKER SAFETY-7.*** *In regards to the mitigation payments, in the absence of adequate and appropriate documentation to the contrary, staff stands by its assessment of the mitigation needs.*

Comment: The RCFD stated support for existing Condition of Certification **WORKER SAFETY-8** and for revised proposed Condition of Certification **WORKER SAFETY-9**.

Response: *Thank you.*

Comment: The RCFD stated support for new Condition of Certification **WORKER SAFETY-10** and suggested that a requirement to pay fees for inspections be added.

Response: *Staff agrees with this suggestion and the proposed Condition of Certification* ***WORKER SAFETY-10*** *has been revised accordingly.*

GALATI BLEK LLP, MARIE FLEMING,PALEN SOLAR HOLDINGS LLC'S FINAL COMMENTS ON THE PSA, TN # 200077, JULY 29, 2013:

In a letter dated July 29, 2013, the Petitioner (Palen Solar Holdings, LLC), made the following written comments (Palen 2013dd):

Comment: WS/FP p.20, 1: agrees with staff's proposed WS-6.

Response: *Thank you.*

Comment: p. 20, 2, WS-7: believes that staff's matrix does not include all projects that may impact RCFD and thus the matrix does not allocate the correct percentages of the needs to the PSEGS

Response: *Staff indicated on page 25 of the PSA (page 26 of this FSA) that the matrix was but one tool staff used to allocate mitigation costs to the PSEGS. Staff believes the matrix to be complete in that it was meant to address only CEC-licensed solar power plants. In the FSA, staff explained that it also relied upon six other criteria including professional opinion, the petitioner's Fire and Emergency Services Risk Assessment, and the comments from the RCFD to determine an appropriate level of mitigation.*

Comment: p. 20, 3, WS-7: urges staff to consider the information contained in the Fire [Needs] Assessment.

Response: *Staff has indeed considered the Fire and Emergency Services Risk Assessment in this FSA.*

Comment: p. 20, 3, WS-7: would like the Commission to note that at no time has Riverside County provided any analysis justifying or providing evidence that it needs the financial support it has requested.

Response: *Staff notes that at the time this submittal was written, this statement was true. It is not now true and staff has considered the two filings by the County of Riverside on this matter.*

Comment: p. 20, 4, WS-7: offers to fund the cost of a medium rescue vehicle and equipment estimated cost $1.2 M.

Response: *Staff agrees with the need for this vehicle, equipment, and training and proposes funding of $1.0 M prior to site mobilization and funds for O&M beginning on the day of site mobilization and annually thereafter after. The net effect of staff's proposal would be an initial total funding of $1.313 M by the start of site preparation.*

Comment: p. 21, 1, WS-7: during construction, fund one Fire Captain and half the cost of a firefighter to staff the rescue unit.

Response: *Staff does not support a bifurcated level of annual mitigation for periods of construction and operations. No case has been made that the need for services (familiarization, plan review, inspections, fire response, hazmat spill response, rescue, EMS) is so substantially different during the periods suggested so as to warrant a greater or lesser payment. While different responses might be needed during different times, the overall net impact remains about the same.*

Comment: p. 21, 1, WS-7: during operation, fund one sixth of the on-going operations cost for one firefighter.

Response: *Staff finds no justification in these comments or in the Fire Risk Assessment for the provision of one-sixth the annual cost of full-time staffing of one firefighter as adequate mitigation during operations.*

Comment: p. 21, 2 & 3, WS-7: want to modify WS-7 as follows: initial payment of $1.2 M, annual payments of $684K for three years, and $144K each year after that.

Response: *Staff has given a great deal of consideration to this proposal and for the reasons stated above on pages 4.14-27 through 4.14-33 of this FSA, believes this proposal provides inadequate mitigation.*

COUNTY OF RIVERSIDE, JOHN J. BENOIT, COMMENTS ON PSA, TN # 200094, JULY 30, 2013:

The County of Riverside (CR 2013a) provided 31 separate and distinct substantive comments and technical arguments that staff has reviewed. Some were comments specifically on the PSA and are listed here while others were more technical in nature and pertained to the issue of impacts and mitigation. Those comments and staff's responses can be found beginning on page 4.14-29 above.

Comment: P. 11, **Worker Safety-1** through **Worker Safety -4**: The County continues to support.

Response: *Staff thanks the County for its support.*

Comment: P. 12, **Worker Safety-5**: The County supports the presence of an on-site Automatic External Defibrillator (AED) program and the concurrent training of sufficient staff. The County also recommends the CEC require that delegated staff be trained in First Aid and CPR.

Response: *Staff agrees and has proposed a revision to Condition **Worker Safety-5**.*

Comment: P. 12, Worker Saftey-5: In addition, the County recommends requiring Trauma/First-Aid kits sufficient to handle anticipated industrial accidents and requests that **Worker Safety-5** be amended to reflect this change.

Response: *Staff agrees and has proposed a revision to Condition **Worker Safety-5**.*

Comment: P. 12, **Worker Safety-6**: Regarding the road access, the County reminds CEC Staff and the applicant that any roads conditioned for fire access must meet Riverside County Fire Standards.

Response: *Staff agrees and it is clear that all LORS must be followed. Also, the specific requirement of the roads being able to handle the weight of a fire engine has been added to **Worker Safety-6.***

Comment: P. 12, 3, **Worker Safety-6:** The accepted life span of a fire apparatus is 20 years – with 15 years generally seen serving in a front-line capacity, and 5 years in reserve. This means these two all-wheel drive fire engines, expected to go into service in 2013, will be scheduled for 15-year replacement in approximately 2028. However, this is only halfway through the anticipated PSEGS life-span of 30 years. The County proposes the project owner be required to pay to Riverside County Fire in engine year 15 the then-current cost difference between two two-wheel drive fire engines and two all-wheel drive fire engines to mitigate the added cost of upgrading these engines.

Response: *Staff understands this matter but does not agree that the PSEGS should be responsible for the costs of mitigation for two 4WD fire engines. Staff also feels that the proposed annual mitigation fee for O&M (Operations and Maintenance) with an annual escalator to account for inflation would be adequate to cover the difference between the cost of a new 2WD fire engine and a new 4WD fire engine.*

Comment: P. 12, ¶4, **Worker Safety-7**: The County disagrees with CEC Staff's conclusions and recommendation on this point. As discussed at length above, RCFD has determined, consistent with the findings of the CEC's own Emergency Response Matrix, that the relative potential risks and hazards posed by this Project, and the corresponding level of emergency response preparedness necessary as a result, remain significant under the proposed change in technology. Furthermore, we have concluded that the change in technology does not afford us any reduction in needed mitigation. This will include the need for increased staffing and equipment, which in turn will entail expanded facilities, as well as ongoing training and planning.

Response: *This issue is discussed in great detail starting on page 14.4-24 above. Staff disagrees that the change in technology does not result in lower impacts and thus warrant a reduction in mitigation, however small that reduction may be. Staff continues to believe that its recommended level of mitigation found in the PSA, with a newly recommended escalator, is the appropriate level.*

Comment: P. 12, ¶5, **Worker Safety-7:** As outlined in more detail in Attachment A to this letter, at this time RCFD has identified the ongoing need for the addition of two additional firefighters per shift at the Blythe Airport Station (#45) an added annual cost in present dollars of $831,000 in addition to the position already added to the Lake Tamarisk Station (#49) at an annual cost of $334,000, and 24/7 coverage by a battalion chief at an annual added cost of $230,000. RCFD has also identified one-time needs for equipment upgrades estimated at $158,000 and technical rescue training totaling $120,000, with ongoing annual training for recertification and skills refreshers totaling $40,000 per year. In addition, to adequately house the additional personnel, trucks and equipment, RCFD will need to expand and/or replace facilities at both the Lake Tamarisk (#49) and Blythe Airport (#45) Fire Stations, at a currently estimated total cost of approximately $5,000,000.

Response: *Staff thanks the RCFD for the detailed cost estimates. This issue is discussed in great detail starting on page 14.4-24 above. Staff believes that the PSEGS should not be responsible for all the above-mentioned upgrades, personnel additions, and training. Staff continues to believe that its recommended level of mitigation found in the PSA, with a newly recommended escalator, will contribute to the funding of the these enhancement at the appropriate level.*

Comment: P. 12, 6: The annual mitigation payment of $375,000 received from the Genesis project is currently being used to support the additional position at the Lake Tamarisk Station, and the anticipated one-time payment of $850,000 from that project will be applied to offset a portion of the anticipated capital costs.

Response: *Thank you for this information.*

Comment: P. 13, 1: Since one of the projects (Blythe) on which these mitigation thresholds were calculated is changing to lower impact photovoltaic technology, and one (Rice) currently appears dormant, it is crucial to the County that at minimum the CEC condition the fire mitigation for PSEGS at the same level previously approved for PSPP. Given that the County is agreeing to accept secondary access gates, rather than insisting on a secondary access road, which will generate significantly greater project savings, the County does not see this request to maintain the previously approved mitigation level to support essential emergency response services as unreasonable.

Response: *This issue is discussed in great detail starting on page 14.4-24 above. Staff notes that mitigation funds will most likely be forthcoming in the future from Rice as it is scheduled to begin construction in March 2014. Staff has no information yet about the modified Blythe project as the decision on the petition is pending. Staff continues, however, to believe that its recommended level of mitigation found in the PSA, with a newly recommended escalator, is the appropriate level and will result in a greater amount of mitigation funds coming to the RCFD than with the current Decision.*

Comment: P. 13, **Worker Safety-8**: The County supports.

Comment: P. 13, **Worker Safety-9**: The County supports.

Comment: P. 13, **Worker Safety-10:** This addresses the need for RCFD to conduct plan checks and provide comments and requires the project owner to pay RCFD its usual and customary fee for the review of those plans. The County requests that RCFD's usual and customary fees for inspections also be paid by the project owner.

Response: *Staff agrees and has revised proposed Condition **Worker Safety-10** to reflect this requirement.*

Comment: P. 13, 3: In addition, the County requests that the following Worker Safety Condition of Certification be added:

Worker Safety – 11: The project owner shall comply with NFPA 56(PS) and not allow any fuel gas pipe cleaning activities on-site, either before placing the pipe into service or at any time during the lifetime of PSEGS, that involve "flammable gas blows" where natural (or flammable) gas is used to blow out debris from piping and then vented to atmosphere. Instead, an inherently safer method involving a non-flammable gas (e.g. air, nitrogen, or steam) or mechanical pigging shall be used. Pursuant to NFPA 56(PS), exceptions to this provision may be allowed only if no other satisfactory method is available, and then only with the approval of the CPM.

Response: *Staff agrees with the County and has placed a new more restrictive condition in the section on **HAZARDOUS MATERIALS MANAGEMENT** as proposed Condition **HAZ-4**.*

Attachment A: The RCFD provided an update on Battalion 8, the RCFD's fire and emergency response unit that covers the desert regions of eastern Riverside County. This Appendix discusses the present state of staffing and infrastructure and recommended staff, equipment, facility, and training enhancement planned or desired for this unit. Staff treated this Appendix as technical information and it thus considered in the discussion of impact mitigation beginning on page 4.14-24 above.

AIRPORT LAND USE COMMISSION, RIVERSIDE COUNTY, ED COOPER, COMMENTS ON THE PSA, TN # 200112, JULY 30, 2013:

In a letter dated July 30, the Riverside County Airport Land Use Commission (CR 2013b) made the following comment and request:

Comment: The thermal plume could affect low-flying emergency medical evacuation helicopters. Provision should be made for the wet surface air cooler, auxiliary boiler, and nighttime boiler to be shut down in the event of an (on-site) emergency requiring an airborne evacuation.

Response: *Staff has reviewed this issue and does not anticipate emergency medical helicopters landing within the heliostat fields due to space constraints or flying into the space between the heliostats and the towers; instead, emergency medical helicopters would likely land at the perimeter of the facility, or in the common area and would not fly through the space between the heliostats and the towers. Staff therefore believes that no helicopters would be at risk from a thermal plume at the site. However, to ensure the safety of medevac helicopters, a revision to Conditions of Certification* ***WORKER SAFETY-1*** *and* ***WORKER SAFETY-2*** *is proposed by staff to include a requirement that the project owner submit an Emergency Medical Evacuation Plan as part of the Emergency Response Plan, one for the construction period and another for operations. The requirement that an Emergency Medical Evacuation be prepared and submitted to the Compliance Project Manager (CPM) for review and approval would ensure that the helicopters are not placed at risk.*

OFFICE OF COUNTY COUNSEL, COUNTY OF RIVERSIDE, TIFFANY NORTH, COMMENTS ON PALEN SOLAR HOLDINGS LLC'S FIRE AND EMERGENCY SERVICES RISK ASSESSMENT FOR PROPOSED PSEGS AMENDMENT, TN # 200211, AUGUST 16, 2013

In a letter dated August 16, 2013, the County of Riverside provided written comments on the petitioner's Fire and Emergency Services Risk Assessment (CR 2013c). Staff has provided detailed responses to 16 separate and distinct substantive comments on pages 4.14-29 through 4.14-33 above.

CONCLUSIONS

Staff concludes that if the project owner for the proposed PSEGS project provides a Project Construction Safety and Health Program and a Project Operations and Maintenance Safety and Health Program as required by Conditions of Certification **WORKER SAFETY-1**, and **-2** and fulfils the requirements of Conditions of Certification **WORKER SAFETY-3** through **-12**, the project would incorporate sufficient measures to ensure adequate levels of industrial safety and comply with applicable LORS. With the implementation of staff's proposed Condition of Certification **WORKER SAFETY-8** (enhanced dust control measures), the potential impacts of Valley Fever would be minimized. Staff also concludes that the operation of this power plant, with mitigation, would not significantly impact the provision of emergency services.

PROPOSED CONDITIONS OF CERTIFICATION

Staff has proposed modifications to the conditions of certification as shown below. (**Note:** Deleted text is in ~~strikethrough~~, new text is **<u>bold and underlined</u>**)

WORKER SAFETY-1 The project owner shall submit to the Compliance Project Manager (CPM) a copy of the Project Construction Safety and Health Program that complies with all applicable federal and state LORS for Worker Safety and Health and includes the following:

- a Construction Personal Protective Equipment Program **<u>(including compliance with ANSI Standard Z87.1-2010 for protective eye wear)</u>;**
- a Construction Exposure Monitoring Program;
- a Construction Injury and Illness Prevention Program, including measures to prevent exposure to Valley Fever;
- a Construction heat stress protection plan that implements and expands on existing Cal-OSHA regulations as found in 8 CCR 3395;
- a Construction Emergency Action Plan **<u>(including an Emergency Medical Evacuation Plan for the period of construction)</u>**;
- **<u>a Construction Flood Safety Plan;</u> and**
- a Construction Fire Prevention Plan that includes the concrete batch plant and the above-ground fuel depot.

The Personal Protective Equipment Program, the Exposure Monitoring Program, the Heat Stress Protection Plan, and the Injury and Illness Prevention Program shall be submitted to the CPM for review and approval concerning compliance of the program with all applicable safety orders. The Construction Emergency Action Plan and the Fire Prevention Plan shall be submitted to the Riverside County Fire Department (RCFD) for review and comment prior to submittal to the CPM for approval.

<u>Verification:</u> At least 30 days prior to the start of construction, the project owner shall submit to the CPM for review and approval a copy of the Project Construction Safety and Health Program. The project owner shall provide a copy of a letter to the CPM from the Riverside County Fire Department stating the fire department's comments on the Construction Fire Prevention Plan and Emergency Action Plan.

WORKER SAFETY-2 The project owner shall submit to the CPM a copy of the Project Operations and Maintenance Safety and Health Program that complies with all applicable federal and state LORS related to Worker Safety and Health and include the following:

- an Operation Injury and Illness Prevention Plan, including measures to prevent exposure to Valley Fever;
- an Operation heat stress protection plan that implements and expands on existing Cal OSHA regulations (8 CCR 3395);
- ~~a Best Management Practices (BMP) for the storage and application of herbicides;~~
- an Emergency Action Plan **<u>(including an Emergency Medical Evacuation Plan for operations)</u>**;
- Hazardous Materials Management Program;
- Fire Prevention Plan that includes the fuel depot should the project owner elect to maintain and operate the fuel depot during operations (8 Cal Code Regs. § 3221) as well as the fire protection measures described in this Decision and any necessary upgrades required by current applicable LORS;
- **<u>An Operations Flood Safety Plan</u>**; **and**
- Personal Protective Equipment Program (8 Cal Code Regs, §§ 3401-3411) **<u>that also includes compliance with ANSI Standard Z87.1-2010 for protective eye wear</u>.**

The Operation Injury and Illness Prevention Plan, Emergency Action Plan, Heat Stress Protection Plan, ~~BMP for Herbicides,~~ and Personal Protective Equipment Program shall be submitted to the CPM for review and comment concerning compliance of the programs with all applicable safety orders. The Fire Prevention Plan and the Emergency Action Plan shall also be submitted to the Riverside County Fire Department for review and comment.

<u>Verification:</u> At least 30 days prior to the start of first-fire or commissioning, the project owner shall submit to the CPM for approval a copy of the Project Operations and Maintenance Safety and Health Program. The project owner shall provide a copy of a letter to the CPM from the Riverside County Fire Department stating the fire department's comments on the Operations Fire Prevention Plan and Emergency Action Plan.

WORKER SAFETY-3 The project owner shall provide a site Construction Safety Supervisor (CSS) who, by way of training and/or experience, is knowledgeable of power plant construction activities and relevant laws, ordinances, regulations, and standards; is capable of identifying workplace hazards relating to the construction activities; and has authority to take appropriate action to assure compliance and mitigate hazards. The CSS shall:

- have overall authority for coordination and implementation of all occupational safety and health practices, policies, and programs;
- assure that the safety program for the project complies with Cal/OSHA and federal regulations related to power plant projects;
- assure that all construction and commissioning workers and supervisors receive adequate safety training;
- complete accident and safety-related incident investigations and emergency response reports for injuries and inform the CPM of safety-related incidents; and
- assure that all the plans identified in Conditions of Certification **WORKER SAFETY-1** and **-2** are implemented.

Verification: At least 30 days prior to the start of site mobilization, the project owner shall submit to the CPM the name and contact information for the Construction Safety Supervisor (CSS). The contact information of any replacement CSS shall be submitted to the CPM within one business day.

The CSS shall submit in the Monthly Compliance Report a monthly safety inspection report to include:

A. A record of all employees trained for that month (all records shall be kept on-site for the duration of the project);

B. A summary report of safety management actions and safety-related incidents that occurred during the month;

C. A report of any continuing or unresolved situations and incidents that may pose danger to life or health; and

D. A report of accidents and injuries that occurred during the month.

WORKER SAFETY-4 The project owner shall make payments to the Chief Building Official (CBO) for the services of a Safety Monitor based upon a reasonable fee schedule to be negotiated between the project owner and the CBO. Those services shall be in addition to other work performed by the CBO. The Safety Monitor shall be selected by and report directly to the CBO and will be responsible for verifying that the Construction Safety Supervisor, as required in Condition of Certification **WORKER SAFETY-3**, implements all appropriate Cal/OSHA and Energy Commission safety requirements. The Safety Monitor shall conduct on-site (including linear facilities) safety inspections at intervals necessary to fulfill those responsibilities.

Verification: At least 30 days prior to the start of construction, the project owner shall provide proof of its agreement to fund the Safety Monitor services to the CPM for review and approval.

WORKER SAFETY-5 The project owner shall ensure that a portable automatic external defibrillator (AED) **and Trauma/First-Aid kits sufficient to handle anticipated industrial accidents are** ~~is~~ located on-site during construction and operations and shall implement a program to ensure that workers are properly trained in ~~its~~ **AED use and basic first aid (which includes CPR)** and that the equipment is properly maintained and functioning at all times. During construction and commissioning, the following persons shall be trained in ~~its~~ **AED use and basic first aid (which includes CPR)** and shall be on-site whenever the workers that they supervise are on-site: the Construction Project Manager or delegate, the Construction Safety Supervisor or delegate, and all shift foremen. During operations, all power place employees shall be trained in ~~its~~ **AED** use **and basic first aid (which includes CPR)**. The training program shall be submitted to the CPM for review and approval.

Verification: At least 60 days prior to the start of site mobilization, the project owner shall submit to the CPM proof that a portable automatic external defibrillator (AED) **and trauma/first aid kits** exist~~s~~ on-site and a copy of the training and maintenance program for review and approval.

WORKER SAFETY-6 The project owner shall:

A. Provide ~~a~~ **not less than two (2)** secondary site access gates for emergency personnel to enter the site**, one on the north site of the site and the other on the south side of the site**. ~~This~~ **These** secondary site access gate**s** shall be **located** at least one-~~quarter~~half mile from the main gate **and shall be equipped with locks that can be opened by emergency response personnel including the Riverside County Fire Department, the Riverside County Sheriff's Department, and the California Highway Patrol**.

~~B.~~ **In lieu of providing** ~~Provide~~ a second access road which provides entry to the site**, the project owner shall share the financial responsibility for the costs of obtaining and maintaining two all-terrain fire engines for the Riverside County Fire Department and shall initially pay to the Genesis Solar Energy Project owner an amount equally to 50 percent of the costs of the engines plus annually 50 percent of the annual maintenance**. ~~This road shall be at a minimum an all-weather gravel road, at least 20 feet wide, and shall come from the Interstate-10 right-of-way to the project site at the location of where the fence line of the eastern solar field comes the nearest to the I-10 right-of-way, if approved by Caltrans, a locked gate shall be placed in the I-10 right-of-way fence. The RCFD, the California Highway Patrol, and the Riverside County Sheriff's Department shall be given access to the gate.~~

C. Maintain the main access road ~~and the second access road~~ and provide a plan for construction and implementation, **<u>and ensure that the main access road and all internal site roads (paved or dirt) are capable of supporting fire engine with a weight of 60,000 pounds.</u>**

Plans for the secondary access gates, the method of gate operation, ~~secondary gravel road,~~ and maintenance of the roads shall be submitted to the Riverside County Fire Department for review and comment and to the CPM for review and approval.

<u>Verification:</u> At least 60 days prior to the start of site mobilization, the project owner shall submit to the RCFD and the CPM preliminary plans showing the **<u>locations of at least two (2)</u>** secondary site access gate<u>s</u> to the site, a description of how the secondary site access gate**<u>s</u>** will be opened by the fire department and other emergency services, and a description and map showing the location, dimensions, and composition of the main road~~, and the gravel road to the secondary site access gate~~.

At least 30 days prior to the start of site mobilization, the project owner shall submit the secondary site access gate<u>s</u> final plans plus the road maintenance plan to the CPM for review and approval. The final plan submittal shall also include a letter containing comments from the Riverside County Fire Department or a statement that no comments were received.

<u>At least 30 days prior to the start of site mobilization, the project owner shall submit to the CPM proof of payment for one-half of the cost of the two all-terrain fire trucks to the Genesis Solar Energy Project owner. In the Project Owners Annual Report, the project owner shall provide proof that it has paid to the Genesis Solar Energy Project owner its share of the annual maintenance costs of the two all-terrain fire trucks.</u>

~~At least 30 days after approval by Caltrans, the project owner shall submit final plans for the gate in the I-10 right-of-way to the Riverside County Fire Department for review and comment and to the CPM for review and approval.~~

WORKER SAFETY-7 The project owner shall ~~either:~~

~~A. Reach an agreement with the Riverside County Fire Department regarding funding of its project-related share of capital costs to build fire protection/response infrastructure and provide appropriate equipment as mitigation of project-related impacts on fire protection services, or, if no agreement can be reached shall~~ fund ~~its share of the~~ capital costs in the amount of ~~$850,000~~ **<u>$1,000,000</u>** and shall provide an annual payment of ~~$375,000~~ **<u>$313,000</u>** to the RCFD ~~for the support of three fire department staff~~ commencing with ~~the date of~~ site mobilization and continuing annually thereafter. **<u>All annual payments after the initial payment shall be subject to an annual escalator equal to the Consumer Price Index (CPI-U, US City Average, All Items Less Food and Energy) for the previous calendar year as published by the U.S Bureau of Labor Statistics to account of inflation</u>** on the anniversary until the final date of power plant **<u>closure</u>**~~decommissioning~~.

Verification: At least 30 days prior to the start of site mobilization, the project owner shall provide **proof** to the CPM ~~for review and approval~~ ~~either:A copy of the agreement with the RCFD or D~~ d~~ocumentation~~ ~~that a letter of credit in the amount of $850,000~~ that **$1,000,000** has been ~~provided~~ paid to the RCFD **for capital costs.**

Documentation that the annual payment of ~~a letter of credit in the amount of $375,000 will be provided~~ **$313,000 has been paid to the RCFD on the first day of site mobilization and each year after that** ~~each year at the start of commercial operations~~. ~~Proof of the annual~~ ~~$375,000 letter of credit~~ ~~payment of $313,333~~ **plus escalator** ~~has been made commencing with site mobilization~~ shall be included each year in the Project Owner's Annual Report to the CPM.

~~**WORKER SAFETY-8** The project owner shall place a water spray system on the two LPG storage tanks. The engineering design plans shall comply with NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection* and be provided to the CPM for review and approval prior to commencing construction of the water spray system.~~

~~**Verification**:~~ ~~At least 30 days prior to site mobilization, the project owner shall provide the engineering design plans to the CPM for review and approval. At least 30 days prior to the delivery of any LPG to the facility, the project owner shall provide a written statement to the CPM that the LPG tank water spray system has been built and successfully tested.~~

WORKER SAFETY-~~9~~8 The project owner shall develop and implement an enhanced Dust Control Plan that includes the requirements described in Conditions **AQ-SC3** and **AQ-SC4**, and additionally requires:

A. Site worker use of dust masks (NIOSH N-95 or better) whenever visible dust is present;

B. ~~Implementation of Rule 402 of the Kern County Air Pollution Control District (as amended Nov. 3, 2004); and~~ **No downwind PM10 ambient concentrations to increase more than 50 micrograms per cubic meter above upwind concentrations as determined by simultaneous upwind and downwind sampling. High-volume particulate matter samplers or other EPA-approved equivalent method(s) for PM10 monitoring shall be used. Samplers shall be:**

a. Operated, maintained, and calibrated in accordance with 40 Code of Federal Regulations (CFR), Part 50, Appendix J, or appropriate EPA-published documents for EPA-approved equivalent methods(s) for PM10 sampling;

b. Reasonably placed upwind and downwind of the large operation based on prevailing wind direction and as close to the property line as feasible, such that other sources of fugitive dust between the sampler and the property line are minimized; and

c. Operated during active operations.

C. Implementation of enhanced dust control methods (increased frequency of watering, use of dust suppression chemicals, etc. consistent with **AQ-SC4**) immediately whenever visible dust persists in the breathing zone of the workers, or when PM10 measurements obtained when implementing B (above) indicate an increase in PM10 concentrations due to project activities of 50 µg/m^3 or more.

Verification: At least 30 days prior to the commencement of site mobilization, the enhanced Dust Control Plan shall be provided to the CPM for review and approval.

WORKER SAFETY-~~10~~9 The project owner shall participate in annual joint training exercises with the Riverside County Fire Department (RCFD). The project owner shall coordinate this training with other Energy Commission-licensed solar power plants within Riverside County such that this project shall host the annual training on a rotating yearly basis with the other solar power plants.

Verification: At least 10 days prior to the start of commissioning, the project owner shall submit to the CPM proof that a joint training program with the RCFD is established. In each January Monthly Compliance Report during construction and the Annual Compliance Report during operation, the project owner shall include the date, list of participants, training protocol, and location of the annual joint training.

WORKER SAFETY-10 The project owner shall submit to the Riverside County Fire Department (RCFD) all plans and schematic diagrams that show the details of all fire detection and suppression systems and shall pay the RCFD its usual and customary fee for the review of those plans and for site inspections after construction but before operations begin. The project owner shall provide proof to the CPM that the plans have been submitted to the RCFD on a timely basis and a copy of the comments received from the RCFD after plan review and after site inspections.

Verification: In each Monthly Compliance Report during construction, the project owner shall include any and all comments received from the RCFD on fire detection and suppression systems and proof that the required plan review and inspection fees have been paid to the fire department.

During operation, the project owner shall provide proof in the Annual Compliance Report that the required inspection fees have been paid to the fire department.

WORKER SAFETY-11 The project owner shall prepare and implement a Tower Access and Safety Plan for the construction phase and one for operations (which includes commissioning). These plans shall include descriptions of the following:

1. **The type of elevators (cage, enclosed, man-lift, etc.) and emergency hoist systems, their capacity in number of people and pounds, the dimensions of the elevator cage or enclosed structure, and a diagram of the emergency hoist systems.**

2. **The primary and secondary (emergency) power supply to the elevators hoist systems and how emergency backup power will be triggered.**

3. <u>The emergency elevator recall system (manual on-site activation, remote from the control room, wired or wireless).</u>

4. <u>The fire detection and suppression systems (fixed and portable) within the towers and in the room at the top of tower behind the boiler.</u>

5. <u>Any planned ventilation systems for inside the towers.</u>

6. <u>The maximum number of workers allowed in each tower at any one time, allowed in the room at the top of each of the towers during periods when the tower will be exposed to solar flux, temperature sensors within the towers and the room at the top, and the expected durations and frequency of this need to have workers at the top of a tower.</u>

7. <u>The manner in which access to the towers and the tower elevators will be controlled, including how a Lockout/Tagout system will be implemented.</u>

8. <u>An Emergency Response Plan that includes a fire suppression plan to respond to emergencies in the tower, the type of PPE that would be available and required for workers both in a tower and those responding to an emergency in a tower to use in the event of a fire or smoke incidence, evacuation of workers, how the emergency hoist systems will be used, and evacuation or rescue of an injured worker from any level of the tower.</u>

9. <u>The project owner shall provide these plans to the CPM for review and approval.</u>

<u>Verification:</u> <u>At least 30 days prior to the start of construction, the project owner shall submit to the CPM for review and approval a copy of the construction Tower Access and Safety Plan. The project owner shall also provide a copy of a letter to the CPM from the RCFD stating the RCFD's comments on the Construction Tower Access and Safety Plan or a letter stating that no comments were received from the RCFD within thirty (30) days of sending the plan to the RCFD.</u>

<u>At least 30 days prior to the start of commissioning (as defined by the CPM), the project owner shall submit to the CPM for review and approval a copy of the Operations Tower Access and Safety Plan. The project owner shall also provide a copy of a letter to the CPM from the RCFD stating the RCFD's comments on the Operations Tower Access and Safety Plan or a letter stating that no comments were received from the RCFD within thirty (30) days of sending the plan to the RCFD.</u>

<u>WORKER SAFETY-12 The project owner shall report to the CPM within 24 hours of any incidence of heat illness (heat stress, exhaustion, stroke, or prostration) occurring in any worker on-site and shall report to the CPM the incidence of any confirmed case of Valley Fever in any worker on the site within 24 hours of receipt of medical diagnosis.</u>

<u>Verification:</u> **<u>The project owner shall provide reports of heat-related and Valley Fever incidences in any worker on the site via telephone call or e-mail to the CPM within 24 hours of a heat-related occurrence or confirmed diagnosis of a case of Valley Fever, and shall include such reports in the Monthly Compliance Report.</u>**

Engineering Assessment

FACILITY DESIGN

Testimony of Shahab Khoshmashrab

SUMMARY OF CONCLUSIONS

The California Energy Commission (Energy Commission) staff (staff) concludes that the design, construction, and eventual closure of the Palen Solar Electric Generating System (PSEGS) and its linear facilities would likely comply with applicable engineering laws, ordinances, regulations and standards. The proposed modifications as described in the Petition to Amend would not change staff's analysis or the conditions of certification as approved in the December 2010 Energy Commission Decision for the approved Palen Solar Power Project (PSPP). The existing conditions of certification below would ensure compliance with these laws, ordinances, regulations and standards.

INTRODUCTION

Facility design encompasses the civil, structural, mechanical, and electrical engineering design of the PSEGS. The purpose of this analysis is to:

- Verify that the laws, ordinances, regulations and standards (LORS) that apply to the engineering design and construction of the project have been identified;
- Verify that both the project and its ancillary facilities are sufficiently described, including proposed design criteria and analysis methods, in order to provide reasonable assurance that the project would be designed and constructed in accordance with all applicable engineering LORS, which would ensure the public health and safety;
- Determine whether special design features should be considered during final design to address conditions unique to the site which could influence public health and safety; and,
- Describe the design review and construction inspection process and establish the conditions of certification used to monitor and ensure compliance with the engineering LORS, in addition to any special design requirements.

Subjects discussed in this analysis include:

- Identification of the engineering LORS that apply to facility design;
- Evaluation of the project owner's proposed design criteria, including identification of criteria essential to public health and safety;
- Proposed modifications and additions provided in the Petition to Amend necessary for compliance with applicable engineering LORS; and
- Conditions of certification proposed by staff to ensure that the project would be designed and constructed to comply with all applicable engineering LORS, which would ensure public health and safety.

LAWS, ORDINANCES, REGULATIONS AND STANDARDS

Lists of LORS applicable to each engineering discipline (civil, structural, mechanical, and electrical) are described in the PSEGS Petition to Amend (Palen 2012a, §§ 2.15.1, 3.1.4, Appendices 2E through 2J). Key LORS are listed in **Facility Design Table 1,** below:

Facility Design Table 1
Key Engineering Laws, Ordinances, Regulations and Standards (LORS)

Applicable LORS	Description
Federal	Title 29 Code of Federal Regulations (CFR), Part 1910, Occupational Safety and Health standards
State	2010 (or latest edition) California Building Standards Code (CBSC) (also known as Title 24, California Code of Regulations)
Local	Riverside County regulations and ordinances
General	American National Standards Institute (ANSI) American Society of Mechanical Engineers (ASME) American Welding Society (AWS) American Society for Testing and Materials (ASTM)

PROPOSED MODIFIED PROJECT

The modifications proposed in the petition include replacing the parabolic trough solar collection system, steam turbine generator, and associated heat transfer fluid with BrightSource's solar tower technology. Heliostats—elevated mirrors guided by a tracking system mounted on a pylon—focus the sun's rays on a solar receiver steam generator (SRSG) located atop a 750-foot-tall tower near the center of each solar field to create steam to drive a turbine that generates electricity. These modifications do not change staff's analysis or conclusions as related to **Facility Design**.

SETTING AND EXISTING CONDITIONS

PSEGS would be built on a site located in Riverside County, California. For more information on the site and its related project description, please see the **PROJECT DESCRIPTION** section of this document. Additional engineering design details are contained in the Petition to Amend, § 3.1.3, Appendices 2E through 2J.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

The purpose of this analysis is to ensure that the project would be built to applicable engineering codes, which would ensure public health and life safety. This analysis further verifies that applicable engineering LORS have been identified and that the project and its ancillary facilities have been described in adequate detail. It also evaluates the project owner's proposed design criteria, describes the design review and construction inspection process, and establishes conditions of certification that would monitor and ensure compliance with engineering LORS and any other special design requirements. These conditions allow both the California Energy Commission (Energy

Commission) compliance project manager (CPM) and the project owner to adopt a compliance monitoring scheme that would verify compliance with these LORS.

SITE PREPARATION AND DEVELOPMENT

Staff has evaluated the proposed design criteria for grading, flood protection, erosion control, site drainage, and site access, in addition to the criteria for designing and constructing linear support facilities such as natural gas and electric transmission interconnections. The project owner proposes the use of accepted industry standards (see Palen 2012a, § 3.1.4, Appendces 2E through 2J for a representative list of applicable industry standards), design practices, and construction methods in preparing and developing the site. Staff concludes that this project, including its linear facilities, would most likely comply with all applicable site preparation LORS, and proposes conditions of certification (see below and the **GEOLOGY AND PALEONTOLOGY** section of this document) to ensure that compliance is met.

MAJOR STRUCTURES, SYSTEMS, AND EQUIPMENT

Major structures, systems, and equipment are structures and their associated components or equipment that are**:** necessary for power production, costly or time consuming to repair or replace**;** are used for the storage, containment, or handling of hazardous or toxic materials**;** or**,** could become potential health and safety hazards if not constructed according to applicable engineering LORS.

PSEGS shall be designed and constructed to the 2010 California Building Standards Code (CBSC), also known as Title 24, California Code of Regulations, which encompasses the California Building Code (CBC), California Building Standards Administrative Code, California Electrical Code, California Mechanical Code, California Plumbing Code, California Energy Code, California Fire Code, California Code for Building Conservation, California Reference Standards Code, and other applicable codes and standards in effect when the design and construction of the project actually begin. If the initial designs are submitted to the chief building official (CBO) for review and approval after the update to the 2010 CBSC takes effect, the 2010 CBSC provisions shall be replaced with the updated provisions.

Certain structures in a power plant may be required, under the CBC, to undergo dynamic lateral force (structural) analysis; others may be designed using the simpler static analysis procedure. In order to ensure that structures are analyzed according to their appropriate lateral force procedure, staff has included Condition of Certification **STRUC-1**, below, which, in part, requires the project CBO's review and approval of the owner's proposed lateral force procedures before construction begins.

PROJECT QUALITY PROCEDURES

The project's Petition to Amend (Palen 2012a, § 3.1.3, Appendices 2E through 2J) describes a quality program intended to inspire confidence that its systems and components will be designed, fabricated, stored, transported, installed, and tested in accordance with all appropriate power plant technical codes and standards. Compliance with design requirements will be verified through specific inspections and audits. Implementation of this quality assurance/quality control (QA/QC) program will ensure that PSEGS is actually designed, procured, fabricated, and installed as described in this analysis.

COMPLIANCE MONITORING

Under California Code of Regulations Title 24, Part 2, Section 104.2 of the CBC, the CBO is authorized and directed to enforce all provisions of the CBC. The Energy Commission itself serves as the building official, and has the responsibility to enforce the code for all of the energy facilities it certifies. In addition, the Energy Commission has the power to interpret the CBC and adopt and enforce both rules and supplemental regulations that clarify application of the CBC's provisions.

The Energy Commission's design review and construction inspection process conforms to CBC requirements and ensures that all facility design conditions of certification are met. As provided by Section 104.2.2 of the CBC, the Energy Commission appoints experts to perform design review and construction inspections and act as delegate CBOs on behalf of the Energy Commission. These delegates typically include the local building official and/or independent consultants hired to provide technical expertise that is not provided by the local official alone. The project owner, through permit fees provided by the CBC, pays the cost of these reviews and inspections. While building permits in addition to Energy Commission certification are not required for this project, the project owner pays in lieu of CBC permit fees to cover the costs of these reviews and inspections.

Staff has developed proposed conditions of certification to ensure public health and safety and compliance with engineering design LORS. Some of these conditions address the roles, responsibilities, and qualifications of the engineers who will design and build the proposed modified project (conditions of certification **GEN-1** through **GEN-8**). These engineers must be registered in California and sign and stamp every submittal of design plans, calculations, and specifications submitted to the CBO. These conditions require that every element of the project's construction (subject to CBO review and approval) be approved by the CBO before it is performed. They also require that qualified special inspectors perform or oversee special inspections required by all applicable LORS.

While the Energy Commission and delegate CBO have the authority to allow some flexibility in scheduling construction activities, these conditions are written so that no element of construction (of permanent facilities subject to CBO review and approval) which could be difficult to reverse or correct can proceed without prior CBO approval. Elements of construction that are not difficult to reverse may proceed without approval of the plans. The project owner bears the responsibility to fully modify construction elements in order to comply with all design changes resulting from the CBO's subsequent plan review and approval process.

FACILITY CLOSURE

The removal of a facility from service, or closure, as a result of the project reaching the end of its useful life, may range from “mothballing” to removal of all equipment and appurtenant facilities and restoration of the site. Future conditions that may affect the closure decision are largely unknown at this time.

In order to assure that closure of the facility will be completed in a manner that is environmentally sound, safe and will protect public health and safety, the project owner shall submit a closure plan to the Energy Commission for review and approval prior to the commencement of closing the facility as required in **COM-15; FACILITY CLOSURE PLANS** in the **GENERAL CONDITIONS** section of this Final Staff Assessment.

The requirements in the **GENERAL CONDITIONS** are adequate protection, even in the unlikely event of project abandonment.

CUMULATIVE IMPACT ANALYSIS

Not applicable.

NOTEWORTHY PUBLIC BENEFITS

Staff has not identified any noteworthy public benefits associated with this **FACILITY DESIGN** section.

RESPONSE TO COMMENTS

Staff received no comments relating to Facility Design.

CONCLUSIONS

The laws, ordinances, regulations and standards (LORS) identified in the Petition to Amend and supporting documents directly apply to the project. Staff has evaluated the proposed engineering LORS, design criteria, and design methods in the record, and concludes that the design, construction, and eventual closure of the project will likely comply with applicable engineering LORS.

The proposed conditions of certification will ensure that PSEGS is designed and constructed in accordance with applicable engineering LORS. This will be accomplished through design review, plan checking, and field inspections that will be performed by the CBO or other Energy Commission delegate. Staff will audit the CBO to ensure satisfactory performance.

Though future conditions that could affect non-operation and facility closure are largely unknown at this time, it can reasonably be concluded that if, the project owner submits a facility closure plan as required in the **GENERAL CONDITIONS** portion of this document prior to facility closure, facility closure procedures will comply with all applicable engineering LORS.

Energy Commission staff recommends that:

1. The proposed conditions of certification be adopted to ensure that the project is designed and constructed in a manner that protects the public health and safety and complies with all applicable engineering LORS;

2. The project be designed and built to the 2010 CBSC (or successor standards, if in effect when initial project engineering designs are submitted for review); and

3. The CBO reviews the final designs, checks plans, and performs field inspections during construction. Energy Commission staff shall audit and monitor the CBO to ensure satisfactory performance.

PROPOSED CONDITIONS OF CERTIFICATION

All the **Facility Design** Conditions of Certification remain unchanged except for a minor edit to update the edition of the CBSC (see below). (**Note:** Deleted text is in ~~strikethrough~~, new text is **bold and underlined.**)

GEN-1 The project owner shall design, construct, and inspect the project in accordance with the ~~2007~~**2010** California Building Standards Code (CBSC), also known as Title 24, California Code of Regulations, which encompasses the California Building Code (CBC), California Building Standards Administrative Code, California Electrical Code, California Mechanical Code, California Plumbing Code, California Energy Code, California Fire Code, California Code for Building Conservation, California Reference Standards Code, and all other applicable engineering LORS in effect at the time initial design plans are submitted to the CBO for review and approval (the CBSC in effect is the edition that has been adopted by the California Building Standards Commission and published at least 180 days previously). The project owner shall ensure that all the provisions of the above applicable codes are enforced during the construction, addition, alteration, moving, demolition, repair, maintenance, or closure of the completed facility. All transmission facilities (lines, switchyards, switching stations and substations) are covered in the conditions of certification in the **TRANSMISSION SYSTEM ENGINEERING** section of this document.

In the event that the initial engineering designs are submitted to the CBO when the successor to the ~~2007~~**2010** CBSC is in effect, the ~~2007~~**2010** CBSC provisions shall be replaced with the applicable successor provisions. Where, in any specific case, different sections of the code specify different materials, methods of construction or other requirements, the most restrictive shall govern. Where there is a conflict between a general requirement and a specific requirement, the specific requirement shall govern.

The project owner shall ensure that all contracts with contractors, subcontractors, and suppliers clearly specify that all work performed and materials supplied comply with the codes listed above.

<u>Verification:</u> Within 30 days following receipt of the certificate of occupancy, the project owner shall submit to the CPM a statement of verification, signed by the responsible design engineer, attesting that all designs, construction, installation, and inspection requirements of the applicable LORS and the Energy Commission's decision have been met in the area of facility design. The project owner shall provide the CPM a copy of the certificate of occupancy within 30 days of receipt from the CBO.

Once the certificate of occupancy has been issued, the project owner shall inform the CPM at least 30 days prior to any construction, addition, alteration, moving, demolition, repair, or maintenance to be performed on any portion(s) of the completed facility that requires CBO approval for compliance with the above codes. The CPM will then determine if the CBO needs to approve the work.

GEN-2 Before submitting the initial engineering designs for CBO review, the project owner shall furnish the CPM and the CBO with a schedule of facility design submittals, and master drawings and master specifications list. The master drawings and master specifications list shall contain a list of proposed submittal packages of designs, calculations, and specifications for major structures, systems, and equipment. Major structures, systems, and equipment are structures and their associated components or equipment that are necessary for power production, costly or time consuming to repair or replace, are used for the storage, containment, or handling of hazardous or toxic materials, or could become potential health and safety hazards if not constructed according to applicable engineering LORS. The schedule shall contain the date of each submittal to the CBO. To facilitate audits by Energy Commission staff, the project owner shall provide specific packages to the CPM upon request.

<u>Verification:</u> At least 60 days (or a project owner- and CBO-approved alternative time frame) prior to the start of rough grading, the project owner shall submit to the CBO and to the CPM the schedule, and the master drawings and master specifications list of documents to be submitted to the CBO for review and approval. These documents shall be the pertinent design documents for the major structures, systems, and equipment defined above in Condition of Certification **GEN-2**. Major structures and equipment shall be added to or deleted from the list only with CPM approval. The project owner shall provide schedule updates in the monthly compliance report.

GEN-3 The project owner shall make payments to the CBO for design review, plan checks, and construction inspections, based upon a reasonable fee schedule to be negotiated between the project owner and the CBO, in accordance with the ~~2007~~**<u>2010</u>** CBC. These fees may be based on the value of the facilities reviewed; may be based on hourly rates; or may be otherwise agreed upon by the project owner and the CBO.

<u>Verification:</u> The project owner shall make the required payments to the CBO in accordance with the agreement between the project owner and the CBO. The project owner shall send a copy of the CBO's receipt of payment to the CPM in the next monthly compliance report indicating that applicable fees have been paid.

GEN-4 Prior to the start of rough grading, the project owner shall assign a California-registered architect, or a structural or civil engineer, as the resident engineer (RE) in charge of the project. All transmission facilities (lines, switchyards, switching stations, and substations) are addressed in the conditions of certification in the **TRANSMISSION SYSTEM ENGINEERING** section of this document.

The RE may delegate responsibility for portions of the project to other registered engineers. Registered mechanical and electrical engineers may be delegated responsibility for mechanical and electrical portions of the project, respectively. A project may be divided into parts, provided that each part is clearly defined as a distinct unit. Separate assignments of general responsibility may be made for each designated part.

The RE shall:

1. Monitor progress of construction work requiring CBO design review and inspection to ensure compliance with LORS;

2. Ensure that construction of all facilities subject to CBO design review and inspection conforms in every material respect to applicable LORS, these conditions of certification, approved plans, and specifications;

3. Prepare documents to initiate changes in approved drawings and specifications when either directed by the project owner or as required by the conditions of the project;

4. Be responsible for providing project inspectors and testing agencies with complete and up-to-date sets of stamped drawings, plans, specifications, and any other required documents;

5. Be responsible for the timely submittal of construction progress reports to the CBO from the project inspectors, the contractor, and other engineers who have been delegated responsibility for portions of the project; and

6. Be responsible for notifying the CBO of corrective action or the disposition of items noted on laboratory reports or other tests when they do not conform to approved plans and specifications.

The resident engineer (or his delegate) must be located at the project site, or be available at the project site within a reasonable period of time, during any hours in which construction takes place.

The RE shall have the authority to halt construction and to require changes or remedial work if the work does not meet requirements.

If the RE or the delegated engineers are reassigned or replaced, the project owner shall submit the name, qualifications and registration number of the newly assigned engineer to the CBO for review and approval. The project owner shall notify the CPM of the CBO's approval of the new engineer.

Verification: At least 30 days (or project owner- and CBO-approved alternative time frame) prior to the start of rough grading, the project owner shall submit to the CBO for review and approval, the resume and registration number of the RE and any other delegated engineers assigned to the project. The project owner shall notify the CPM of the CBO's approvals of the RE and other delegated engineer(s) within five days of the approval.

If the RE or the delegated engineer(s) is subsequently reassigned or replaced, the project owner has five days to submit the resume and registration number of the newly assigned engineer to the CBO for review and approval. The project owner shall notify the CPM of the CBO's approval of the new engineer within five days of the approval.

GEN-5 Prior to the start of rough grading, the project owner shall assign at least one of each of the following California registered engineers to the project: a civil engineer; a soils, geotechnical, or civil engineer experienced and knowledgeable in the practice of soils engineering; and an engineering geologist. Prior to the start of construction, the project owner shall assign at least one of each of the following California registered engineers to the project: a design engineer who is either a structural engineer or a civil engineer fully competent and proficient in the design of power plant structures and equipment supports; a mechanical engineer; and an electrical engineer. (California Business and Professions Code section 6704 et seq., and sections 6730, 6731 and 6736 require state registration to practice as a civil engineer or structural engineer in California). All transmission facilities (lines, switchyards, switching stations, and substations) are handled in the conditions of certification in the **TRANSMISSION SYSTEM ENGINEERING** section of this document.

The tasks performed by the civil, mechanical, electrical, or design engineers may be divided between two or more engineers, as long as each engineer is responsible for a particular segment of the project (for example, proposed earthwork, civil structures, power plant structures, equipment support). No segment of the project shall have more than one responsible engineer. The transmission line may be the responsibility of a separate California registered electrical engineer.

The project owner shall submit, to the CBO for review and approval, the names, qualifications, and registration numbers of all responsible engineers assigned to the project.

If any one of the designated responsible engineers is subsequently reassigned or replaced, the project owner shall submit the name, qualifications and registration number of the newly assigned responsible engineer to the CBO for review and approval. The project owner shall notify the CPM of the CBO's approval of the new engineer.

A. The civil engineer shall:

   1. Review the foundation investigations, geotechnical, or soils reports prepared by the soils engineer, the geotechnical engineer, or by a civil engineer experienced and knowledgeable in the practice of soils engineering;

   2. Design (or be responsible for the design of), stamp, and sign all plans, calculations, and specifications for proposed site work, civil works, and related facilities requiring design review and inspection by the CBO. At a minimum, these include: grading, site preparation, excavation, compaction, construction of secondary containment, foundations, erosion and sedimentation control structures, drainage facilities, underground utilities, culverts, site access roads and sanitary sewer systems; and

   3. Provide consultation to the RE during the construction phase of the project and recommend changes in the design of the civil works facilities and changes to the construction procedures.

B. The soils engineer, geotechnical engineer, or civil engineer experienced and knowledgeable in the practice of soils engineering, shall:

   1. Review all the engineering geology reports;

   2. Prepare the foundation investigations, geotechnical, or soils reports containing field exploration reports, laboratory tests, and engineering analysis detailing the nature and extent of the soils that could be susceptible to liquefaction, rapid settlement or collapse when saturated under load;

   3. Be present, as required, during site grading and earthwork to provide consultation and monitor compliance with requirements set forth in the ~~2007~~**2010** CBC (depending on the site conditions, this may be the responsibility of either the soils engineer, the engineering geologist, or both); and

   4. Recommend field changes to the civil engineer and RE.

   This engineer shall be authorized to halt earthwork and to require changes if site conditions are unsafe or do not conform to the predicted conditions used as the basis for design of earthwork or foundations.

C. The engineering geologist shall:

   1. Review all the engineering geology reports and prepare a final soils grading report; and

2. Be present, as required, during site grading and earthwork to provide consultation and monitor compliance with the requirements set forth in the ~~2007~~**2010** CBC (depending on the site conditions, this may be the responsibility of either the soils engineer, the engineering geologist, or both).

D. The design engineer shall:

1. be directly responsible for the design of the proposed structures and equipment supports;

2. Provide consultation to the RE during design and construction of the project;

3. Monitor construction progress to ensure compliance with engineering LORS;

4. Evaluate and recommend necessary changes in design; and

5. Prepare and sign all major building plans, specifications, and calculations.

E. The mechanical engineer shall be responsible for, and sign and stamp a statement with, each mechanical submittal to the CBO, stating that the proposed final design plans, specifications, and calculations conform to all of the mechanical engineering design requirements set forth in the Energy Commission's decision.

F. The electrical engineer shall:

1. be responsible for the electrical design of the project; and

2. Sign and stamp electrical design drawings, plans, specifications, and calculations.

Verification: At least 30 days (or project owner- and CBO-approved alternative time frame) prior to the start of rough grading, the project owner shall submit to the CBO for review and approval, resumes and registration numbers of the responsible civil engineer, soils (geotechnical) engineer and engineering geologist assigned to the project.

At least 30 days (or project owner- and CBO-approved alternative time frame) prior to the start of construction, the project owner shall submit to the CBO for review and approval, resumes and registration numbers of the responsible design engineer, mechanical engineer, and electrical engineer assigned to the project.

The project owner shall notify the CPM of the CBO's approvals of the responsible engineers within five days of the approval.

If the designated responsible engineer is subsequently reassigned or replaced, the project owner has five days in which to submit the resume and registration number of the newly assigned engineer to the CBO for review and approval. The project owner shall notify the CPM of the CBO's approval of the new engineer within five days of the approval.

GEN-6 Prior to the start of an activity requiring special inspection, including prefabricated assemblies, the project owner shall assign to the project, qualified and certified special inspector(s) who shall be responsible for the special inspections required by the ~~2007~~**2010** CBC. All transmission facilities (lines, switchyards, switching stations, and substations) are handled in conditions of certification in the **TRANSMISSION SYSTEM ENGINEERING** section of this document.

A certified weld inspector, certified by the American Welding Society (AWS), and/or American Society of Mechanical Engineers (ASME) as applicable, shall inspect welding performed on-site requiring special inspection (including structural, piping, tanks and pressure vessels).

The special inspector shall:

1. Be a qualified person who shall demonstrate competence, to the satisfaction of the CBO, for inspection of the particular type of construction requiring special or continuous inspection;

2. Inspect the work assigned for conformance with the approved design drawings and specifications;

3. Furnish inspection reports to the CBO and RE. All discrepancies shall be brought to the immediate attention of the RE for correction, then, if uncorrected, to the CBO and the CPM for corrective action; and

4. Submit a final signed report to the RE, CBO, and CPM, stating whether the work requiring special inspection was, to the best of the inspector's knowledge, in conformance with the approved plans, specifications, and other provisions of the applicable edition of the CBC.

Verification: At least 15 days (or project owner- and CBO-approved alternative time frame) prior to the start of an activity requiring special inspection, the project owner shall submit to the CBO for review and approval, with a copy to the CPM, the name(s) and qualifications of the certified weld inspector(s), or other certified special inspector(s) assigned to the project to perform one or more of the duties set forth above. The project owner shall also submit to the CPM a copy of the CBO's approval of the qualifications of all special inspectors in the next monthly compliance report.

If the special inspector is subsequently reassigned or replaced, the project owner has five days in which to submit the name and qualifications of the newly assigned special inspector to the CBO for approval. The project owner shall notify the CPM of the CBO's approval of the newly assigned inspector within five days of the approval.

GEN-7 If any discrepancy in design and/or construction is discovered in any engineering work that has undergone CBO design review and approval, the project owner shall document the discrepancy and recommend required corrective actions. The discrepancy documentation shall be submitted to the CBO for review and approval. The discrepancy documentation shall reference this condition of certification and, if appropriate, applicable sections of the CBC and/or other LORS.

Verification: The project owner shall transmit a copy of the CBO's approval of any corrective action taken to resolve a discrepancy to the CPM in the next monthly compliance report. If any corrective action is disapproved, the project owner shall advise the CPM, within five days, of the reason for disapproval and the revised corrective action to obtain CBO's approval.

GEN-8 The project owner shall obtain the CBO's final approval of all completed work that has undergone CBO design review and approval. The project owner shall request the CBO to inspect the completed structure and review the submitted documents. The project owner shall notify the CPM after obtaining the CBO's final approval. The project owner shall retain one set of approved engineering plans, specifications, and calculations (including all approved changes) at the project site or at another accessible location during the operating life of the project. Electronic copies of the approved plans, specifications, calculations, and marked-up as-builts shall be provided to the CBO for retention by the CPM.

Verification: Within 15 days of the completion of any work, the project owner shall submit to the CBO, with a copy to the CPM, in the next monthly compliance report, (a) a written notice that the completed work is ready for final inspection, and (b) a signed statement that the work conforms to the final approved plans. After storing the final approved engineering plans, specifications, and calculations described above, the project owner shall submit to the CPM a letter stating both that the above documents have been stored and the storage location of those documents.

Within 90 days of the completion of construction, the project owner shall provide to the CBO three sets of electronic copies of the above documents at the project owner's expense. These are to be provided in the form of "read only" (Adobe .pdf 6.0) files, with restricted (password-protected) printing privileges, on archive quality compact discs.

CIVIL-1 The project owner shall submit to the CBO for review and approval the following:

1. Design of the proposed drainage structures and the grading plan;
2. An erosion and sedimentation control plan;
3. Related calculations and specifications, signed and stamped by the responsible civil engineer; and
4. Soils, geotechnical, or foundation investigations reports required by the ~~2007~~**2010** CBC.

Verification: At least 15 days (or project owner- and CBO-approved alternative time frame) prior to the start of site grading the project owner shall submit the documents described above to the CBO for design review and approval. In the next monthly compliance report following the CBO's approval, the project owner shall submit a written statement certifying that the documents have been approved by the CBO.

CIVIL-2 The resident engineer shall, if appropriate, stop all earthwork and construction in the affected areas when the responsible soils engineer, geotechnical engineer, or the civil engineer experienced and knowledgeable in the practice of soils engineering identifies unforeseen adverse soil or geologic conditions. The project owner shall submit modified plans, specifications, and calculations to the CBO based on these new conditions. The project owner shall obtain approval from the CBO before resuming earthwork and construction in the affected area.

Verification: The project owner shall notify the CPM within 24 hours, when earthwork and construction is stopped as a result of unforeseen adverse geologic/soil conditions. Within 24 hours of the CBO's approval to resume earthwork and construction in the affected areas, the project owner shall provide to the CPM a copy of the CBO's approval.

CIVIL-3 The project owner shall perform inspections in accordance with the ~~2007~~ **2010** CBC. All plant site-grading operations, for which a grading permit is required, shall be subject to inspection by the CBO.

If, in the course of inspection, it is discovered that the work is not being performed in accordance with the approved plans, the discrepancies shall be reported immediately to the resident engineer, the CBO, and the CPM. The project owner shall prepare a written report, with copies to the CBO and the CPM, detailing all discrepancies, non-compliance items, and the proposed corrective action.

Verification: Within five days of the discovery of any discrepancies, the resident engineer shall transmit to the CBO and the CPM a non-conformance report (NCR), and the proposed corrective action for review and approval. Within five days of resolution of the NCR, the project owner shall submit the details of the corrective action to the CBO and the CPM. A list of NCRs, for the reporting month, shall also be included in the following monthly compliance report.

CIVIL-4 After completion of finished grading and erosion and sedimentation control and drainage work, the project owner shall obtain the CBO's approval of the final grading plans (including final changes) for the erosion and sedimentation control work. The civil engineer shall state that the work within his/her area of responsibility was done in accordance with the final approved plans.

Verification: Within 30 days (or project owner- and CBO-approved alternative time frame) of the completion of the erosion and sediment control mitigation and drainage work, the project owner shall submit to the CBO, for review and approval, the final grading plans (including final changes) and the responsible civil engineer's signed statement that the installation of the facilities and all erosion control measures were completed in accordance with the final approved combined grading plans, and that the facilities are adequate for their intended purposes, along with a copy of the transmittal letter to the CPM. The project owner shall submit a copy of the CBO's approval to the CPM in the next monthly compliance report.

STRUC-1 Prior to the start of any increment of construction, the project owner shall submit plans, calculations and other supporting documentation to the CBO for design review and acceptance for all project structures and equipment identified in the CBO-approved master drawing and master specifications lists. The design plans and calculations shall include the lateral force procedures and details as well as vertical calculations.

Construction of any structure or component shall not begin until the CBO has approved the lateral force procedures to be employed in designing that structure or component.

The project owner shall:

1. Obtain approval from the CBO of lateral force procedures proposed for project structures;

2. Obtain approval from the CBO for the final design plans, specifications, calculations, soils reports, and applicable quality control procedures. If there are conflicting requirements, the more stringent shall govern (for example, highest loads, or lowest allowable stresses shall govern). All plans, calculations, and specifications for foundations that support structures shall be filed concurrently with the structure plans, calculations, and specifications;

3. Submit to the CBO the required number of copies of the structural plans, specifications, calculations, and other required documents of the designated major structures prior to the start of on-site fabrication and installation of each structure, equipment support, or foundation;

4. Ensure that the final plans, calculations, and specifications clearly reflect the inclusion of approved criteria, assumptions, and methods used to develop the design. The final designs, plans, calculations, and specifications shall be signed and stamped by the responsible design engineer; and

5. Submit to the CBO the responsible design engineer's signed statement that the final design plans conform to applicable LORS.

Verification: At least 60 days (or project owner- and CBO-approved alternative time frame) prior to the start of any increment of construction of any structure or component listed in the CBO-approved master drawing and master specifications list, the project owner shall submit to the CBO the above final design plans, specifications and calculations, with a copy of the transmittal letter to the CPM.

The project owner shall submit to the CPM, in the next monthly compliance report, a copy of a statement from the CBO that the proposed structural plans, specifications, and calculations have been approved and comply with the requirements set forth in applicable engineering LORS.

STRUC-2 The project owner shall submit to the CBO the required number of sets of the following documents related to work that has undergone CBO design review and approval:

1. Concrete cylinder strength test reports (including date of testing, date sample taken, design concrete strength, tested cylinder strength, age of test, type and size of sample, location and quantity of concrete placement from which sample was taken, and mix design designation and parameters);

2. Concrete pour sign-off sheets;

3. Bolt torque inspection reports (including location of test, date, bolt size, and recorded torques);

4. Field weld inspection reports (including type of weld, location of weld, inspection of non-destructive testing (NDT) procedure and results, welder qualifications, certifications, qualified procedure description or number (ref: AWS); and

5. Reports covering other structural activities requiring special inspections shall be in accordance with the ~~2007~~**2010** CBC.

Verification: If a discrepancy is discovered in any of the above data, the project owner shall, within five days, prepare and submit an NCR describing the nature of the discrepancies and the proposed corrective action to the CBO, with a copy of the transmittal letter to the CPM. The NCR shall reference the condition(s) of certification and the applicable CBC chapter and section. Within five days of resolution of the NCR, the project owner shall submit a copy of the corrective action to the CBO and the CPM.

The project owner shall transmit a copy of the CBO's approval or disapproval of the corrective action to the CPM within 15 days. If disapproved, the project owner shall advise the CPM, within five days, the reason for disapproval, and the revised corrective action to obtain CBO's approval.

STRUC-3 The project owner shall submit to the CBO design changes to the final plans required by the U.S Energy Information Administration, "Natural Gas Pipelines in the Western Region, ~~2007~~**2010** CBC, including the revised drawings, specifications, calculations, and a complete description of, and supporting rationale for, the proposed changes, and shall give to the CBO prior notice of the intended filing.

Verification: On a schedule suitable to the CBO, the project owner shall notify the CBO of the intended filing of design changes, and shall submit the required number of sets of revised drawings and the required number of copies of the other above-mentioned documents to the CBO, with a copy of the transmittal letter to the CPM. The project owner shall notify the CPM, via the monthly compliance report, when the CBO has approved the revised plans.

STRUC-4 Tanks and vessels containing quantities of toxic or hazardous materials exceeding amounts specified in the ~~2007~~**2010** CBC shall, at a minimum, be designed to comply with the requirements of that chapter.

Verification: At least 30 days (or project owner- and CBO-approved alternate time frame) prior to the start of installation of the tanks or vessels containing the above specified quantities of toxic or hazardous materials, the project owner shall submit to the CBO for design review and approval final design plans, specifications, and calculations, including a copy of the signed and stamped engineer's certification.

The project owner shall send copies of the CBO approvals of plan checks to the CPM in the following monthly compliance report. The project owner shall also transmit a copy of the CBO's inspection approvals to the CPM in the monthly compliance report following completion of any inspection.

MECH-1 The project owner shall submit, for CBO design review and approval, the proposed final design, specifications and calculations for each plant major piping and plumbing system listed in the CBO-approved master drawing and master specifications list. The submittal shall also include the applicable QA/QC procedures. Upon completion of construction of any such major piping or plumbing system, the project owner shall request the CBO's inspection approval of that construction.

The responsible mechanical engineer shall stamp and sign all plans, drawings, and calculations for the major piping and plumbing systems, subject to CBO design review and approval, and submit a signed statement to the CBO when the proposed piping and plumbing systems have been designed, fabricated, and installed in accordance with all of the applicable laws, ordinances, regulations and industry standards, which may include, but are not limited to:

- American National Standards Institute (ANSI) B31.1 (Power Piping Code);
- ANSI B31.2 (Fuel Gas Piping Code);
- ANSI B31.3 (Chemical Plant and Petroleum Refinery Piping Code);
- ANSI B31.8 (Gas Transmission and Distribution Piping Code);
- NACE R.P. 0169-83;
- NACE R.P. 0187-87;
- NFPA 56;
- Title 24, California Code of Regulations, Part 5 (California Plumbing Code);

- Title 24, California Code of Regulations, Part 6 (California Energy Code, for building energy conservation systems and temperature control and ventilation systems);
- Title 24, California Code of Regulations, Part 2 (California Building Code); and
- San Diego County codes.

The CBO may deputize inspectors to carry out the functions of the code enforcement agency.

Verification: At least 30 days (or project owner- and CBO-approved alternative time frame) prior to the start of any increment of major piping or plumbing construction listed in the CBO-approved master drawing and master specifications list, the project owner shall submit to the CBO for design review and approval the final plans, specifications, and calculations, including a copy of the signed and stamped statement from the responsible mechanical engineer certifying compliance with applicable LORS, and shall send the CPM a copy of the transmittal letter in the next monthly compliance report.

The project owner shall transmit to the CPM, in the monthly compliance report following completion of any inspection, a copy of the transmittal letter conveying the CBO's inspection approvals.

MECH-2 For all pressure vessels installed in the plant, the project owner shall submit to the CBO and California Occupational Safety and Health Administration (Cal-OSHA), prior to operation, the code certification papers and other documents required by applicable LORS. Upon completion of the installation of any pressure vessel, the project owner shall request the appropriate CBO and/or Cal-OSHA inspection of that installation.

The project owner shall:

1. Ensure that all boilers and fired and unfired pressure vessels are designed, fabricated, and installed in accordance with the appropriate section of the American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel Code, or other applicable code. Vendor certification, with identification of applicable code, shall be submitted for prefabricated vessels and tanks; and

2. Have the responsible design engineer submit a statement to the CBO that the proposed final design plans, specifications, and calculations conform to all of the requirements set forth in the appropriate ASME Boiler and Pressure Vessel Code or other applicable codes.

Verification: At least 30 days (or project owner- and CBO-approved alternative time frame) prior to the start of on-site fabrication or installation of any pressure vessel, the project owner shall submit to the CBO for design review and approval, the above listed documents, including a copy of the signed and stamped engineer's certification, with a copy of the transmittal letter to the CPM.

The project owner shall transmit to the CPM, in the monthly compliance report following completion of any inspection, a copy of the transmittal letter conveying the CBO's and/or Cal-OSHA inspection approvals.

MECH-3 The project owner shall submit to the CBO for design review and approval the design plans, specifications, calculations, and quality control procedures for any heating, ventilating, air conditioning (HVAC) or refrigeration system. Packaged HVAC systems, where used, shall be identified with the appropriate manufacturer's data sheets.

The project owner shall design and install all HVAC and refrigeration systems within buildings and related structures in accordance with the CBC and other applicable codes. Upon completion of any increment of construction, the project owner shall request the CBO's inspection and approval of that construction. The final plans, specifications and calculations shall include approved criteria, assumptions, and methods used to develop the design. In addition, the responsible mechanical engineer shall sign and stamp all plans, drawings and calculations and submit a signed statement to the CBO that the proposed final design plans, specifications and calculations conform with the applicable LORS.

Verification: At least 30 days (or project owner- and CBO-approved alternative time frame) prior to the start of construction of any HVAC or refrigeration system, the project owner shall submit to the CBO the required HVAC and refrigeration calculations, plans, and specifications, including a copy of the signed and stamped statement from the responsible mechanical engineer certifying compliance with the CBC and other applicable codes, with a copy of the transmittal letter to the CPM.

ELEC-1 Prior to the start of any increment of electrical construction for all electrical equipment and systems 480 Volts or higher (see a representative list, below), with the exception of underground duct work and any physical layout drawings and drawings not related to code compliance and life safety, the project owner shall submit, for CBO design review and approval, the proposed final design, specifications, and calculations. Upon approval, the above listed plans, together with design changes and design change notices, shall remain on the site or at another accessible location for the operating life of the project. The project owner shall request that the CBO inspect the installation to ensure compliance with the requirements of applicable LORS. All transmission facilities (lines, switchyards, switching stations, and substations) are handled in conditions of certification in the **TRANSMISSION SYSTEM ENGINEERING** section of this document.

A. Final plant design plans shall include:

1. one-line diagrams for the 13.8 kV, 4.16 kV and 480 V systems; and

2. System grounding drawings.

B. Final plant calculations must establish:

   1. Short-circuit ratings of plant equipment;

   2. Ampacity of feeder cables;

   3. Voltage drop in feeder cables;

   4. System grounding requirements;

   5. Coordination study calculations for fuses, circuit breakers and protective relay settings for the 13.8 kV, 4.16 kV and 480 V systems;

   6. System grounding requirements; and

   7. Lighting energy calculations.

C. The following activities shall be reported to the CPM in the monthly compliance report:

   1. Receipt or delay of major electrical equipment;

   2. Testing or energization of major electrical equipment; and

   3. A signed statement by the registered electrical engineer certifying that the proposed final design plans and specifications conform to requirements set forth in the Energy Commission decision.

<u>Verification:</u> At least 30 days (or project owner- and CBO-approved alternative time frame) prior to the start of each increment of electrical construction, the project owner shall submit to the CBO for design review and approval the above listed documents. The project owner shall include in this submittal a copy of the signed and stamped statement from the responsible electrical engineer attesting compliance with the applicable LORS, and shall send the CPM a copy of the transmittal letter in the next monthly compliance report.

GEOLOGY AND PALEONTOLOGY

Testimony of Casey Weaver, CEG

SUMMARY OF CONCLUSIONS

The proposed Palen Solar Electric Generating System (PSEGS) is located in a moderately active geologic area of the eastern Mojave Desert geomorphic province in eastern Riverside County in southeastern California. The main geologic hazards at this site include strong ground shaking, hydrocompaction, dynamic compaction, expansive soils, and corrosive soils. These potential hazards can be effectively mitigated through facility design by incorporating recommendations contained in a design-level geotechnical report as required by the California Building Code (CBC 2010) and Condition of Certification GEO-1. Conditions of Certification **GEN-1, GEN-5,** and **CIVIL-1** in the **FACILITY DESIGN** section, should also mitigate these impacts to a less than significant level.

The proposed project area is currently not used for mineral production, nor is it under claim, lease, or permit for the production of locatable, leasable, or salable minerals. Sand and gravel resources are present at the site and could potentially be a source of salable resources; however, such materials are present throughout the regional area such that the PSEGS should not have a significant impact on the availability of such resources. There are no other known viable geologic or mineralogic resources at the PSEGS site.

Based on its independent research and review, Energy Commission staff believes that the potential is low for significant adverse impacts to the proposed project from geologic hazards during its design life and to potential geologic and mineralogic, resources from the construction, operation, and closure of the proposed project.

Locally, paleontological resources have been documented within lacustrine sediments in nearby Ford Dry Lake, and regionally in older Quaternary alluvium. Older alluvium and lacustrine deposits may underlie younger Quaternary alluvium at an undetermined, but potentially shallow, depth beneath the site surface. Potential impacts to paleontologic resources would be mitigated through worker training and monitoring by qualified paleontologists, as required by Conditions of Certification, **PAL-1** through **PAL-8** in areas where soils are exposed by conventional excavation operations. In areas where heliostats are to be supported by pylons that are vibro-inserted into the ground, there may be impacts to paleontological resources – any resource present would be crushed without being identified. Existing studies indicate the soils beneath the solar field are likely to contain Pleistocene age vertebrate fossils. Staff has determined that based on existing information, the use of this technology would result in a significant impact.

In order to adequately mitigate for the potential impacts to paleontological resources in the subsurface soils where heliostat pylons are proposed, a subsurface paleontological characterization must be performed in accordance with Condition of Certification **PAL-9**. The characterization will allow for the refinement of various mitigation options including fossil recovery and data collection, avoidance, and modifications of pylon insertion to be implemented as appropriate to ensure significant impacts are mitigated.

INTRODUCTION

In this section, staff discusses the potential impacts of geologic hazards on the proposed PSEGS site as well as the project's potential impacts to geologic, mineralogic, and paleontologic resources. Staff's objective is to ensure that there will be no consequential adverse impacts to significant geologic and paleontologic resources during the project construction, operation, and closure and that operation of the plant will not expose occupants to high-probability geologic hazards. A brief geologic and paleontologic overview is provided. The section concludes with staff's proposed monitoring and mitigation measures for geologic hazards and geologic, mineralogic, and paleontologic resources, with proposed Conditions of Certification.

METHODOLOGY AND THRESHOLDS FOR DETERMINING ENVIRONMENTAL CONSEQUENCES

The CEQA Guidelines, Appendix G, provide a checklist of questions that lead agencies typically address.

- Section (V) (c) includes guidelines that determine if a project will either directly or indirectly destroy a unique paleontologic resource or site or a unique geologic feature.
- Sections (VI) (a), (b), (c), (d), and (e) focus on whether or not the project would expose persons or structures to geologic hazards.
- Sections (X) (a) and (b) concern the project's effects on mineral resources.

The California Building Standards Code (CBSC) and CBC (2010) provide geotechnical and geologic investigation and design guidelines, which engineers must follow when designing a facility. As a result, the criteria used to assess the significance of a geologic hazard include evaluating each hazard's potential impact on the design and construction of the proposed facility. Geologic hazards include faulting and seismicity, liquefaction, dynamic compaction, hydrocompaction, subsidence, expansive soils, corrosive soils, landslides, tsunamis, and seiches. Of these, dynamic compaction, hydrocompaction, subsidence, corrosive soils, and expansive soils are geotechnical engineering issues, but are not normally associated with concerns for public safety.

Staff has reviewed geologic and mineral resource maps for the surrounding area, as well as site-specific information provided by the applicant of the previously-approved PSPP project ("the PSPP applicant"), to determine if geologic and mineralogic resources exist in the area and to determine if operations could adversely affect geologic and mineralogic resources.

To evaluate whether the proposed project and alternatives would generate a potentially significant impact as defined by CEQA on mineral resources, staff evaluated them against checklist questions posed in the 2006 CEQA Guidelines, Appendix G, *Environmental Checklist established for Mineral Resources*. These questions are:

A. Would the project result in the loss of availability of a known mineral resource that would be of value to the region and residents of the state?

B. Would the project result in the loss of availability of a locally-important mineral resource recovery site delineated on a local general plan, specific plan, or other land use plan?

Staff reviewed existing paleontologic information and requested records searches from the Natural History Museum of Los Angeles County (NHMLA) and the University of California Museum of Paleontology (UCMP) online database for the site area. Site-specific information generated by the PSPP applicant for the previously-approved PSPP project was also reviewed. All research was conducted in accordance with accepted assessment protocol (SVP 1995) to determine whether any known paleontologic resources exist in the general area. If present or likely to be present, conditions of certification which outline required procedures to mitigate impacts to potential resources are proposed as part of the project's approval.

The Antiquities Act of 1906 (16 United States Code [§§431-433]) requires that objects of antiquity be taken into consideration for federal projects and the CEQA, Appendix G, also requires the consideration of paleontologic resources. The Paleontological Resources Preservation Act of 2009 requires the Secretaries of the United States Department of the Interior and Agriculture to manage and protect paleontologic resources on Federal land using scientific principles and expertise. The potential for discovery of significant paleontologic resources or the impact of surface disturbing activities to such resources is assessed using the Potential Fossil Yield Classification (PFYC) system. This system includes three conditions (Condition 1 [areas known to contain vertebrate fossils]; Condition 2 [areas with exposures of geological units or settings that have high potential to contain vertebrate fossils]; and Condition 3 [areas that are very unlikely to produce vertebrate fossils]). The PFYC class ranges from Class 5 (very high) for Condition 1 to Class 1 (very low) for Condition 3 (USDI 2007).

The existing Conditions of Certification allow the Energy Commission's compliance project manager (CPM) and the project owner to adopt a compliance monitoring scheme ensuring compliance with laws, ordinances, regulations, and standards (LORS) applicable to geologic hazards and the protection of geologic, mineralogic, and paleontologic resources.

Based on the information below, it is staff's opinion that where there is the potential for significant adverse impacts to the project from geologic hazards, and to potential geologic, mineralogic, and paleontologic resources from the proposed project will be mitigated to less than significant with the implementation of staff's recommended conditions of certification.

LAWS, ORDINANCES, REGULATIONS, AND STANDARDS (LORS)

Applicable LORS are listed in the application for certification (AFC) (Solar Millennium 2009a). The following briefly describes the current LORS for both geologic hazards and resources and mineralogic and paleontologic resources.

Geology and Paleontology Table 1
Laws, Ordinances, Regulations, and Standards (LORS)

Applicable LORS	Description
Federal	
Antiquities Act of 1906 (16 United States Code [USC], 431-433)	The proposed PSEGS facility site is located entirely on land currently administered by the Bureau of Land Management (BLM). Although there is no specific mention of natural or paleontologic resources in the Act itself, or in the Act's uniform rules and regulations (Title 43 Part 3, Code of Federal Regulations [43 CFR Part 3], 'objects of antiquity' has been interpreted to include fossils by the Federal Highways Act of 1956, the National Park Service (NPS), the BLM, the Forest Service (USFS), and other Federal agencies.
Federal Land Policy and Management Act (FLPMA) of 1976 (43 USC 1701-1784)	Mandates that the BLM manage public lands under the principles of multiple use and sustained yield unless otherwise specified by law, and to protect the quality scientific, scenic, historical, archeological, and other values, and to develop 'regulations and plans for the protection of public land areas of critical environmental concern', which include 'important historic, cultural or scenic values'. Also charged with the protection of 'life and safety from natural hazards'.
Paleontologic Resources Preservation Act (PRPA) of 2009 (Public Law [PL] 111-011)	Authorizes Departments of Interior and Agriculture Secretaries to manage the protection of paleontologic resources on Federal lands.
National Historic Preservation Act of 1966 (NHPA) (16 USC 470)	Establishes policies for the 'preservation of the prehistoric and historic resources of the United States', under the direction of the Secretary of the Interior and the BLM.
State	
California Building Code (CBC), 2007	The CBC (2007) includes a series of standards that are used in project investigation, design, and construction (including grading and erosion control).
Alquist-Priolo Earthquake Fault Zoning Act, Public Resources Code (PRC), section 2621–2630	Mitigates against surface fault rupture of known active faults beneath occupied structures. Requires disclosure to potential buyers of existing real estate and a 50-foot setback for new occupied buildings. Portions of the site and proposed ancillary facilities are located within designated Alquist-Priolo Fault Zones. The proposed site layout places occupied structures outside of the 50-foot setback zone.
The Seismic Hazards Mapping Act, PRC Section 2690–2699	Areas are identified that are subject to the effects of strong ground shaking, such as liquefaction, landslides, tsunamis, and seiches.
PRC, Chapter 1.7, sections 5097.5 and 30244	Regulates removal of paleontologic resources from state lands, defines unauthorized removal of fossil resources as a misdemeanor, and requires mitigation of disturbed sites.
Local	
Riverside County General Plan 2000, Safety Element	Adopts the Uniform Building Code (UBC) (1997), which provides design criteria for buildings and excavations. The UBC is superseded by the CBC (2007). Requires mitigation measures for geologic hazards, including seismic shaking, surface rupture (adopts APEFZ Act), liquefaction, unstable soils and slopes, and flooding.

Applicable LORS	Description
Local	
Riverside County General Plan 2000, Multipurpose Open Space Element	Provides for 'preservation of cultural, historical, archaeological, paleontologic, geologic and educational resources'. Also provides a map showing paleontologic sensitivity in the county.
Standards	
Society for Vertebrate Paleontology (SVP), 2010	The "Measures for Assessment and Mitigation of Adverse Impacts to Non-Renewable Paleontological Resources: Standard Procedures" is a set of procedures and standards for assessing and mitigating impacts to vertebrate paleontological resources. The measures were adopted in October 1995 and revised in 2010 by the SVP, a national organization of professional scientists.
Bureau of Land Management (BLM) Instructional Memorandum 2008-009	Provides up-to-date methodologies for assessing paleontological sensitivity and management guidelines for paleontological resources on lands managed by the Bureau of Land Management.

PROPOSED PROJECT

Each solar plant will be constructed using the following specifications:

Spread Footings

For most of the PSEGS project power block and common areas, shallow footings would be on the order of 1'-6" to 4'-0" thick with approximate top of footing set 2 ft +/- below grade requiring between 3'-6" to 6'-0" of excavation.

Slabs and Mat Foundations – Buildings and small equipment

Slabs and mat foundations placed near grade elevation can range from 0'-6" to 4'-0" thick and may be placed at grade level. Over-excavation of poor surface soils to 2'-0" depth that extends up to 5'-0" beyond the slab or mat may be required in accordance with the preliminary geotechnical report.

Large Foundations

Deeper mat foundations for the solar tower and STG are sized based on the preliminary geotechnical report that was prepared and submitted as part of the PSPP. Foundation design site parameters need to be verified with a specific soils investigation that addresses the power block foundation requirements. Note that an increase in the depth of these foundations requires an increase in the footing width to maintain the same contact pressure. The suggested foundation sizes can also be used as a pile supported mat, should further geotechnical investigation indicate the soil supported settlements are greater than currently anticipated.

Solar Tower

At the Solar Tower, the footing size would be 195 ft octagonal diameter (across flats) with a depth of 6'-0" below finish grade and soil disturbance to 8'-6" below grade.

Steam Turbine Generator (STG)

At the STG foundation, the mat will range from 3'-0" thick at the Lube Oil and Excitation Container area to between 6'-6" to 8'-0" thick under the STG and may extend beyond the edges of the STG unit to pick up the adjacent equipment skids.

Heliostats

Each solar plant will use approximately 85,000 heliostats—elevated mirrors guided by a tracking system mounted on a pylon—to focus the sun's rays on a SRSG atop a tower near the center of each solar field. The support pylons for the heliostats will be installed using vibratory technology to insert the pylons into the ground (pre-augering prior to the installation of the pylon may be required). Depths are not expected to be greater than 12 feet. The heliostat assembly (mirrors, support structure and aiming system) will be mounted on the pylon. The majority of the project site will maintain the original grades and natural drainage features and, therefore, construction will require machines that are maneuverable and can negotiate the terrain.

Onsite Electric Transmission System

The onsite electric transmission system would consist of underground cables to convey power from the power blocks to the switchyard. The cables would be routed under the paved access roads. A cable serving Solar Plant #2 will be routed to Solar Plant #1 and the cables will be routed in parallel to the common switchyard before transitioning to overhead structures and exiting the site. The installation of the transmission system would involve trenching to accommodate the underground electric transmission lines. The trench depth is expected to be up to 10 feet. Manholes located at intervals of approximately 1,000 to 2,000 feet may require excavation up to depths of 12 feet.

Generation Tie-line

A slight re-routing of the generation tie-line near the western end of the route and around the newly constructed Red Bluff Substation is proposed. The purpose of this re-routing is to align the PSEGS generation tie-line route immediately adjacent to the NextEra Desert Sunlight generation tie-line to minimize crossings over Interstate-10 and to ensure easy entry into the Red Bluff Substation nearest the PSEGS breaker position.

SETTING AND EXISTING CONDITIONS

Depending on the published reference, the project site is located in either the southeastern portion of the Mojave Desert geomorphic province (CGS 2002a), or the northeastern quarter of the Colorado Desert geomorphic province (Norris and Webb 1990), in the Mojave Desert of southern California near the Arizona border. Geologically and geographically the area is more characteristic of the Mojave Desert geomorphic province. The Mojave Desert is a broad interior region of isolated mountain ranges which separate vast expanses of desert plains and interior drainage basins. The physiographic province is wedge-shaped and separated from the Sierra Nevada and Basin and Range geomorphic provinces by the northeast-striking Garlock Fault on the northwest side. The northwest-striking San Andreas Fault defines the southwestern boundary, beyond which lie the Transverse Ranges. The Colorado Desert geomorphic province lies to the south and east of the project area. The topography and structural fabric in the Mojave Desert is predominately southeast to northwest, and is associated with mid-Miocene to recent faulting oriented similar to the San Andreas Fault. A secondary east to west orientation correlates with structural trends in the Transverse Ranges geomorphic province.

The site is situated on a broad alluvial plain within the northwest-trending Chuckwalla Valley between the Chuckwalla Mountains to the southwest, and the Palen Mountains to the northeast. Overall the proposed site slopes at very shallow grades north and northeast toward the local topographic low at Palen Dry Lake.

Quaternary age alluvial, lacustrine and eolian sedimentary deposits are mapped in the vicinity of the proposed PSEGS site (CDMG 1967; USGS 1989; USGS 1990). The local stratigraphy as interpreted by different authors is presented in **Geology and Paleontology Table 2**.

Geology and Paleontology Table 2
Correlation and Ages of Stratigraphic Units

Age	Unit/Description	Jennings (CDMG 1967)	Stone & Pelka (USGS 1989)	Stone (USGS 1990)
Holocene	Eolian sands	Qs	Qs	Qs
	Younger alluvium	Qal	Qya	Qta
	Playa lake deposits	Ql	Qp	Qp
Pleistocene	Older alluvium	Qc	Qia	Qta
			Qoa	

Holocene units, which include eolian sands, younger alluvium, and playa lake deposits, are mapped over nearly the entire site surface. Eolian sands consist of unconsolidated deposits of well sorted, windblown sand in dunes and sheets. Younger alluvium is composed of sand, pebbly sand and sandy pebble-gravel, and is generally coarser grained closer to mountain ranges. Desert varnish is not well developed in the mostly unconsolidated and undissected sediments. Playa lake deposits are also unconsolidated, and are comprised of clay, silt and sand. Older alluvium is present at the surface along the southwestern edge of the site. The exposures of older alluvium occur as northeast-oriented ridges of material protruding into the site from the southwest, with the intervening areas occupied by drainages filled with younger alluvium. Older alluvium is composed of consolidated gravel and sand that is moderately dissected with moderately developed desert pavement and varnish.

Exploration drilling conducted in 1978 by the U.S. Geological Survey (USGS) resulted in two boreholes in the Palen Dry Lake area, one of which lies within the boundaries of the site. U.S. Geological Survey Borehole PDL#1 was advanced to a depth of 505 feet below ground surface (bgs) near the north-central boundary of Section 27 near the northeast corner of the proposed project. The lithologic log of PDL#1 indicates the subsurface near the northern site boundary is composed of moderately to thickly bedded sands, gravels, and clays to a depth of approximately 55 feet where a transition to overall clay dominated formation takes place and continues to the total depth of the borehole. The interbedded clays, sands, and gravels probably represent periods of primarily lakebed deposition interspersed with episodes of coarse sediment transport from the nearby Chuckwalla and Palen Mountains. A gravel dominated bed present from approximately 90 to 110 feet also attests to a period of clastic deposition during a period of primarily lakebed sedimentation (Simoni Jr. 1981). Water wells 05S17E33N001S and 06S/17E-03M01S, which were drilled in 1958 in what is now the southeast portion of the proposed PSEGS site reportedly had a similar stratigraphic column with coarse alluvium from the surface to between 48 and 102 feet overlying strata which are clay dominated to the bottom of the well borings at depths between 758 feet and 818 feet bgs (PSEGS 2009).

A preliminary geotechnical investigation including 13 exploratory borings and eight test pits has been completed for the general area of the PSEGS site (Kleinfelder 2009). The preliminary geotechnical investigation reveals that the PSEGS site is underlain by alluvial and eolian deposits of Pleistocene through Holocene age, which consist of dune sands, alluvium and lake deposits to the depths explored (approximately 76.5 feet below the existing ground surface). The PSEGS site is generally surfaced with unconsolidated soils due to desiccation and/or wind deposition to a maximum depth of 2 feet below the existing grade. The soils below the surficial materials are generally medium dense to very dense poorly graded sand with varying amounts of silt, silty sand and clayey sand. Firm to very hard sandy clays are locally present as interbedded layers 5 to 10 feet thick at depths generally greater than 25 feet below existing grade. The near surface site soils are primarily granular with no to low swell potential; however, potentially expansive soils were observed at the ground surface in the northeastern portion of the site (Kleinfelder 2009). Loose dune sand was also observed at the ground surface and at depth in the southwestern portion of the site (Kleinfelder 2009). Collapse potential tests indicate the site soils exhibit a collapse potential in the range of 0 to 3.0 percent when inundated with water.

The site is not crossed by any known active faults or designated Alquist-Priolo Earthquake Fault Zone (EFZ, formerly called Special Studies Zones) (CGS 2002b). A number of major, active faults lie within 62 miles of the site. These faults are discussed in detail under the **GEOLOGIC HAZARDS** section later in this section. Several northwest-striking, south-dipping basement thrust faults are mapped at the extreme southern end of the Palen Mountains, and are inferred beneath Quaternary and Tertiary sediments in Chuckwalla Valley (Harding and Coney 1985; CDMG 1967; USGS 1990; USGS 2006). These faults are part of a major Mesozoic terrain-bounding structural zone that was active during late Jurassic time, and are associated with folding and metamorphism in the Palen and McCoy Mountains. The basement faults are no longer active, and are not exposed anywhere on the surface of the proposed site.

Little is known regarding the depth to bedrock beneath the proposed PSEGS site. Gravity investigations indicate the Chuckwalla Valley overlies three alluvium filled sub-basins separated by east to northeast-trending subsurface basement ridges. Gravity data indicate basin fill in Chuckwalla Valley ranges from approximately 650 feet deep across faulted subsurface basement ridges to greater than 6,000 feet deep near the sub-basin centers. Analysis of gravity anomalies indicates the crystalline basement beneath the sediment filled basins is highly faulted and structurally complex (Rotstein et al. 1976). Review of gravity anomaly data suggests the proposed PSEGS site is underlain at an undetermined depth by faulted tertiary non-marine and marine sedimentary, pyroclastic, and volcanic rocks.

The ground water level beneath the site was measured as part of the PSPP applicant's water resources investigation. Depth to water beneath the site in well 06S/17E-03M01S was reportedly 180 feet bgs on May 22, 2009 (PSEGS 2009). Subsurface exploration performed at the site (Kleinfelder 2009) encountered ground water at depths of 68 and 73 feet below existing grade; however, this occurrence of ground water is believed to be associated with perched conditions and not indicative of the true water table.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

This section considers two types of impacts. The first is geologic hazards, which could impact the proper functioning of the proposed facility and create life/safety concerns. The second is the potential impacts the proposed facility could have on existing geologic, mineralogic, and paleontologic resources in the area.

DIRECT/INDIRECT IMPACTS AND MITIGATION

Ground shaking, hydrocompaction, dynamic compaction, expansive soils, and corrosive soils represent the main geologic hazards at the proposed site. These potential hazards could be effectively mitigated through facility design by incorporating recommendations contained in the project geotechnical evaluation as required by **GEO-1**. Conditions of Certification **GEN-1, GEN-5,** and **CIVIL-1** in the **FACILITY DESIGN** section should also mitigate these impacts to a less than significant level.

The site is currently not used for mineral production, nor is it under claim, lease, or permit for the production of locatable, leasable, or salable minerals. Sand and gravel resources are present at the site; however, such materials are present throughout the regional area such that the PSEGS should not have a significant impact on the availability of such resources. In addition, the potential resource would become available again following facility closure. Only limited exploration for oil and gas resources has been performed in the area, and no active oil or gas operations are located in the immediate vicinity of the project. As a result, the PSEGS would not impact any current or reasonably foreseeable development of geologic or mineral resources.

Staff has reviewed the paleontologic resources assessment in Section 5.9 and Appendix H of the AFC (Solar Millennium 2009a; SWCA 2009). Staff has also reviewed correspondence from NHMLA (McLeod 2009); UCMP; and the Riverside County Land Information System (RCLIA 2009) for information regarding known fossil localities and stratigraphic unit sensitivity within the proposed project area. All research was conducted in accordance with accepted assessment protocol (SVP 1995) to determine whether any known paleontologic resources exist in the general area. If present or likely to be present, Conditions of Certification which outline required procedures to mitigate impacts to potential resources are included as part of the projects approval.

Based on the above research, SVP criteria, the paleontologic report appended to the AFC (Solar Millennium 2009a) and the confidential paleontologic information filing (Solar Millennium 2009b), staff considers that there is a high probability that paleontologic resources will be encountered during grading and excavation in the older Quaternary age alluvial and lacustrine sediments. Further, deeper excavations in the younger alluvium that will encounter the underlying older Quaternary age alluvial soils will also have a high probability to encounter paleontologic resources. Conditions of Certification **PAL-1** to **PAL-8** are designed to mitigate potential impacts to paleontologic resources to less than significant levels in areas where conventional excavation operations occur. These Conditions of Certification essentially require a worker education program in conjunction with the monitoring of earthwork activities by a qualified professional paleontologist (paleontologic resource specialist [PRS]).

As stated above, existing information indicates that site soils have a high probability of containing fossils. The approved project proposed substantial site grading and excavation. Using conventional excavation methods, fossils encountered during construction would have been uncovered, discovered, collected and recorded, thereby contributing to the scientific understanding of the paleoclimate and paleobiology of the area. The proposed project would use a different construction methodology. Rather than parallel rows of mirrors suspended on level linear lattice structures, the proposed project would install 170,000 individual pole structures (pylons) to support heliostat mirrors (85,000 heliostats per solar unit). The pylons would be installed by vibro-insertion methods. Each pylon would be attached to a specialized piece of equipment that would drive each pylon through the soil column to a final depth of approximately 12 feet below ground surface. This method of construction does not utilize excavation and there is no retrieval of subsurface soils or any fossils contained within those soils. In effect, any fossils that are in the path of pylon insertion would be permanently destroyed with no recovery, discovery or scientific benefit realized.

Staff has determined that based on existing information, the use of this technology would result in a significant impact.

In order to adequately mitigate for the potential impacts to paleontological resources in the subsurface soils where heliostat pylons are proposed, a subsurface paleontological characterization must be performed in accordance with Condition of Certification **PAL-9**. The characterization will allow for the refinement of various mitigation options including fossil recovery and data collection, avoidance, and modifications of post insertion to be implemented as appropriate to ensure significant impacts are mitigated.

The existing Conditions of Certification allow the Energy Commission's CPM and the project owner to adopt a compliance monitoring scheme ensuring compliance with LORS applicable to geologic hazards and the protection of geologic and mineralogic resources.

Geologic Hazards

Review of the AFC (Solar Millennium 2009a) and the site-specific subsurface information (Kleinfelder 2009), coupled with staff's independent research, indicate that the possibility of geologic hazards significantly affecting the operation of the plant site during its practical design life is low. However, geologic hazards must be addressed in a design-level project geotechnical report per CBC (2010) requirements and Condition of Certification GEO-1.

Staff's independent research included the review of available geologic maps, reports, and related data of the site. Geologic information was available from the California Geological Survey (CGS), California Division of Mines and Geology (CDMG, now known as CGS), the USGS, the American Geophysical Union, the Geologic Society of America, the Southern California Earthquake Data Center (SCEDC), and other organizations.

Faulting and Seismicity

Energy Commission staff reviewed numerous CGS, CDMG and USGS publications as well as informational websites in order to gather data on the location, timing and type of faulting in the proposed project area. Type A and B faults within 63 miles (100 kilometers) of the site are listed in **Geology and Paleontology Table 3**. Type A faults have slip-rates of $\geq$5 mm per year and are capable of producing an earthquake of magnitude 7.0 or greater. Type B faults have slip-rates of 2 to 5 mm per year and are capable of producing an earthquake of magnitude 6.5 to 7.0. The fault type, potential magnitude, and distance from the site are summarized in **Geology and Paleontology Table 3**. Because of the large size of the proposed site, the distances to faults are measured from a point between the two proposed power blocks within the site.

Geology and Paleontology Table 3
Active Faults Relative to the Proposed Palen Solar Electric Generating System Site

Fault Name	Distance from Site (miles)	Maximum Earthquake Magnitude (Mw)	Fault Type and Strike	Fault Class
Brawley Seismic Zone	37.0	6.4	Right-Lateral Strike Slip (Northwest)	A
San Andreas: Coachella M-1c-5	37.0	7.2	Right-Lateral Strike Slip (Northwest)	A
San Andreas SB-Coachella M-1b-2	37.0	7.7	Right-Lateral Strike Slip (Northwest)	A
San Andreas: Whole	37.0	8.0	Right-Lateral Strike Slip (Northwest)	A
Elmore Ranch	40.6	6.6	Left-Lateral Strike Slip (Northeast)	B
Pinto Mountain	50.8	7.2	Left-Lateral Strike Slip (East-West)	B
Pisgah-Bullion Mountain–Mesquite Lake	54.9	7.3	Right-Lateral Strike Slip (Northwest)	B
Imperial	57.4	7.0	Right-Lateral Strike Slip (Northwest)	A
Superstition Hills	59.0	6.6	Right-Lateral Strike Slip (Northwest)	A
San Jacinto–Anza	60.0	7.2	Right-Lateral Strike Slip (Northwest)	A
Superstition Mtn.	62.1	6.6	Right-Lateral Strike Slip (Northwest)	A

Type C and otherwise undifferentiated faults which are more than 20 miles from the site are not discussed here because they are unlikely to undergo movement or generate seismicity which could affect the project.

Eleven Type A and B faults and fault segments were identified within 63 miles of the site (**Geology and Paleontology Table 3).** Of these, none are within 35 miles of the site. Eight of the faults are Type A right-lateral, northwest-trending strike-slip fault systems that are part of or subparallel to the San Andreas Fault System. Two of the remaining three faults are Type B, are east-west to northeast-striking, and are left-lateral strike-slip faults with characteristics similar to the Garlock Fault, which bounds the northwestern side of the Mojave Desert geomorphic province (CGS 2002a). All fault zones in

Geology and Paleontology Table 3 are subject to the Alquist-Priolo Earthquake Fault Zoning Act of 1972 (CDMG 2003).

The site is located just southwest of the Mojave-Sonoran Belt, a roughly 60-mile-wide structural belt that has been correlated with the southern extension of the Walker Lane Fault Zone (USGS 1991). The western boundary for the structural zone, located 5 to10 miles northeast of the proposed site, is marked by an abrupt termination of north- and northeast-trending mountain ranges and basins to the east that are characteristic of the San Andreas Fault Zone, and northwest-trending strike-slip faulting to the west. The Mojave-Sonoran Belt is notable for its relative lack of seismicity and recent faulting (USGS 1991). The region has experienced a low frequency of Pliocene faulting, and Pleistocene faults are nearly absent. These characteristics are unusual given its proximity to areas of intense faulting and frequent seismicity, such as the Eastern California Shear Zone (Dokka and Travis 1990) to the northwest and the Salton Trough to the southwest.

The close proximity of the site to the Mojave-Sonoran belt and relatively great distance from more seismically active areas to the west and northwest would suggest a relatively low to moderate probability of intense ground shaking in the project area. However, events such as the Landers earthquake (M7.6), which occurred on June 28, 1992 approximately 78 miles from the site (Blake 2000b), demonstrate that the site could be subject to moderate levels of earthquake-related ground shaking in the future.

Preliminary estimates of ground motion based on probabilistic seismic hazard analyses have also been calculated for the project site using the USGS Earthquake Hazards application called the U.S. Seismic "DesignMaps" Web Application (Geology and Paleontology Table 4). This application produces seismic hazard curves, uniform hazard response spectra, and seismic design values. The values provided by this application are based upon data from the 2008 USGS National Seismic Hazard Mapping Project. These design parameters are for use with the 2012 International Building Code, the 2010 ASCE-7 Standard, the 2009 NEHRP Provisions, and their respective predecessors.

These parameters are project-specific and, based on PSEG's location, were calculated using latitude and longitude inputs of 33.691degrees north and 115.198 degrees west, respectively. Other inputs for this application are the site "type" which is based on the underlying geologic materials and the "Structure Risk Category". The assumed site class for PSEG is "D", which is applicable to stiff soil. These parameters can be updated as appropriate following the results presented in a project-specific geotechnical investigation report performed for the site. The assumed "Structure Risk Category" is "III", which is based on its inherent risk to people and the need for the structure to function following a damaging event. Risk categories range from I (non essential) to IV (critical). Examples of risk category I include agriculture facilities, minor storage facilities, etc., while examples of category IV include fire stations, hospitals, nuclear power facilities, etc.

Geology and Paleontology Table 4
Planning Level 2010 CBC Seismic Design Parameters Maximum Considered Earthquake, ASCE 7 Standard

Parameter	Value
Assumed Site Class	D
Structure Risk Category	III - Substantial
SS – Mapped Spectral Acceleration, Short (0.2 Second) Period	0.657 g
S1 – Mapped Spectral Acceleration, Long (1.0 Second) Period	0.289 g
Fa – Site Coefficient, Short (0.2 Second) Period	1.275
Fv – Site Coefficient, Long (1.0 Second) Period	1.823
SDS – Design Spectral Response Acceleration, Short (0.2 Second) Period	0.558 g
SD1 – Design Spectral Response Acceleration, Long (1.0 Second) Period	0.351 g
SMS – Spectral Response Acceleration, Short (0.2 Second) Period	0.837 g
SM1 – Spectral Response Acceleration, Long (1.0 Second) Period	0.526 g

ASCE = American Society of Civil Engineers
Values from USGS 2010b

The ground acceleration values presented are typical for the area. Other developments in the adjacent area will also be designed to accommodate strong seismic shaking. The potential for and mitigation of the effects of strong seismic shaking during an earthquake should be addressed in a project-specific geotechnical report, per CBC 2010 requirements, and Condition of Certification **GEO-1** and Facility Design Conditions of Certification **GEN-1**, **GEN-5** and **CIVIL-1**. Compliance with these conditions of certification would ensure the project is built to current seismic standards and potential impacts would be mitigated to insignificant levels in accordance with current standards of engineering practice.

Liquefaction

Liquefaction is a condition in which a saturated cohesionless soil may lose shear strength because of sudden increase in pore water pressure caused by an earthquake. However, the potential for liquefaction of strata deeper than approximately 40 feet below surface is considered negligible due to the increased confining pressure and because geologic strata at this depth are generally too compact to liquefy.

The site is located within an area with low to moderate level of liquefaction potential as delineated by RCLIA (2009). However, the estimated depth to ground water based on measured values in boreholes and wells near the proposed site is greater than 60 feet below existing grade (Kleinfelder 2009; Solar Millennium 2009a). In addition, the typical medium dense to very dense nature of the coarse grain soils encountered in the PSEGS borings (Kleinfelder 2009) indicates that there is no liquefaction potential at the site (Kleinfelder 2009).

Lateral Spreading

Lateral spreading of the ground surface can occur within liquefiable beds during seismic events. Lateral spreading generally requires an abrupt change in slope; that is, a nearby steep hillside or deeply eroded stream bank. Other factors such as distance from the epicenter, magnitude of the seismic event, and thickness and depth of liquefiable layers also affect the amount of lateral spreading. Because the site is not subject to catastrophic liquefaction-induced settlement, the potential for lateral spreading during seismic events would be negligible due to the low relief and very shallow slopes at the site surface.

Dynamic Compaction

Dynamic compaction of soils results when relatively unconsolidated granular materials experience vibration associated with seismic events. The vibration causes a decrease in soil volume, as the soil grains tend to rearrange into a more dense state (an increase in soil density). The decrease in volume can result in settlement of overlying structural improvements. The site is generally underlain by medium-dense to very-dense granular soils. However, loose sand layers are occasionally present at the surface and as buried layers at the site (Kleinfelder 2009). The potential for and mitigation of the effects of dynamic compaction of site soils during an earthquake should be addressed in a project-specific geotechnical report as required by the CBC (2010) and Condition of Certification **GEO-1**. Common mitigation methods include deep foundations (driven piles; drilled shafts) for severe conditions, geogrid-reinforced fill pads for moderate severity and over-excavation and replacement for areas of minimal hazard.

Hydrocompaction

Hydrocompaction (also known as hydro-collapse) is generally limited to young soils that were deposited rapidly in a saturated state, most commonly by a flash flood. The soils dry quickly, leaving an unconsolidated, low density deposit with a high percentage of voids. Foundations built on these types of compressible materials can settle excessively, particularly when landscaping irrigation dissolves the weak cementation that is preventing the immediate collapse of the soil structure. The depositional environment of the Chuck-walla Valley suggests that the soils may be subjected to hydrocompaction. The project geotechnical report indicates that there is a low to moderate hydrocompaction potential based on the geotechnical data and the observation of soil profile in the test pits (Kleinfelder 2009). The potential for and mitigation of the effects of hydrocompaction of site soils should be addressed in a project-specific geotechnical report as required by the CBC (2007) and Condition of Certification **GEO-1**. Typical mitigation measures would include over-excavation/replacement, mat foundations or deep foundations depending on severity and foundation loads.

Subsidence

The Riverside County General Plan indicates the basin fill sediments in Chuckwalla Valley are susceptible to subsidence (RCLIA 2008). Regional ground subsidence is typically caused by petroleum or ground water withdrawal that increases the effective unit weight of the soil profile, which in turn increases the effective stress on the deeper soils. This results in consolidation or settlement of the underlying soils. However, even during the 1980’s and 1990’s when regional ground water extraction was at its historic maximum of approximately 48,000 acre-feet per year (ac-ft/yr) no localized or regional subsidence was recorded. Current ground water withdrawals are approximately 2,000 ac-ft/yr and even the proposed project demand of an additional 201 ac-ft/yr will not approach historic pumping demands. Additional information with respect to historical and anticipated ground water pumping is contained in the **SOIL AND WATER RESOURCES** section. In addition, no petroleum or natural gas withdrawals are taking place in the proposed site vicinity. Therefore, the potential for local or regional ground subsidence resulting from petroleum, natural gas, or ground water extraction is considered to be very low.

Local subsidence or settlement may also occur when areas containing compressible soils are subjected to foundation or fill loads. The typical medium dense to very dense granular site soils are indicative of low to negligible local subsidence. Clay layers present at depth are typically deeper than the anticipated zone of influence of shallow foundations and would therefore not be subjected to consolidation settlement from surcharge loading from conventional shallow foundations.

Expansive Soils

Soil expansion occurs when clay-rich soils with an affinity for water exist in place at a moisture content below their plastic limit. The addition of moisture from irrigation, precipitation, capillary tension, water line breaks, etc. causes the clay soils to absorb water molecules into their structure, which in turn causes an increase in the overall volume of the soil. This increase in volume can correspond to excessive movement (heave) of overlying structural improvements. The preliminary geotechnical report for the project did encounter potentially expansive clay soils at the ground surface in the northeastern portion of the site (Kleinfelder 2009). However, interbedded layers of clay soils are present in the subsurface soil profile in this area. As a result, there is the potential for expansive soils to be present at the locations of proposed structural improvements. The potential for and mitigation of the effects of expansive site soils should be addressed in a project-specific geotechnical report as required by the CBC (2010) and Condition of Certification **GEO-1**. Typical mitigation measures would include over-excavation/replacement or deep foundations depending on severity and foundation loads.

Corrosive Soils

Fine grain soils with high in-situ moisture contents that contain sulfides can be corrosive to buried metal pipe, which can lead to premature pipe failure and leaking. Such soils are present at this site, and the preliminary geotechnical investigation (Kleinfelder 2009) indicates that site soils could be potentially corrosive to metal pipe. The effects of corrosive soils can be effectively mitigated through final design by incorporating the recommendations of the site-specific project geotechnical report required by the CBC and Condition of Certification **GEO-1**. Mitigation of corrosive soils with respect to metal pipe typically involves cathodic protection or polyethylene encasement of the pipe.

Landslides

Due to the low site gradient and the absence of topographically high ground in the immediate site vicinity, the potential for landslide impacts to the site is considered to be negligible.

Flooding

The PSEGS area has not been mapped by the Federal Emergency Management Agency (FEMA) for flood potential (FEMA 2009). Because the site is topographically higher than Palen Dry Lake to the north, it is staff's opinion that the potential for flooding at the site is limited to infrequent high volume (flash flood) events which may occur due to heavy rainfall in the Chuckwalla Mountains southwest of the site. Storm waters would be carried across the proposed site from roughly southwest to northeast via existing drainages. Site drainage would be modified during project construction and other engineering improvements will also be made to mitigate potential impacts due to catastrophic flooding (Solar Millennium 2009). Additional information is contained in the **SOIL AND WATER RESOURCES** section.

Tsunamis and Seiches

The proposed PSEGS site is not located near any significant surface water bodies, and therefore the potential for impacts due to tsunamis and seiches is considered to be negligible.

Volcanic Hazards

The site is located approximately 40 miles west of the Lavic Lake volcanic hazard area (VHA), an approximately 14-square-mile area within the Mojave Desert comprised of Miocene to Holocene age dacitic to basaltic flows, pyroclastic rocks, and volcaniclastic sediments (Glazner 2000). The Lavic Lake VHA has been designated by the USGS as an area subject to lava flows and tephra deposits associated with basalt or basaltic andesite vents (Miller 1989). The Amboy Crater – Lavic Lake VHS is also considered to be subject to future formation of cinder cones, volcanic ash falls, and phreatic explosions. The recurrence interval for eruptions has not been determined, but is likely to be in the range of one thousand years or more. Because the site is not located within a designated volcanic hazard area, staff considers the likelihood of significant impacts to the project resulting from volcanic activity would be low.

Geologic, Mineralogic, and Paleontologic Resources

Geologic and Mineralogic Resources

Staff has reviewed applicable geologic maps and reports for this area (Blake 2000a and b; CDMG 1990; CDMG 1994a and b; CDMG 1998; CDMG 1999; CDMG 2003; CGS 2002a, b and c; CGS 2007; Jennings and Saucedo 2002; Kleinfelder 2009; SCEDC 2008; USGS 2003; USGS 2008a and b). The site is currently not used for mineral production, nor is it under claim, lease, or permit for the production of locatable, leasable, or salable minerals. Sand and gravel resources are present at the site and could potentially be a source of salable resources; however, such materials are present throughout the regional area such that the PSEGS should not have a significant impact on the availability of such resources.

The proposed PSEGS site is mapped as Mineral Resource Zone (MRZ)-4 (CDMG 1994a). Mineral Resource Zone-4 refers to "areas of no known mineral occurrences where geologic information does not rule out either the presence or absence of industrial mineral resources".

No economically viable mineral deposits are known to be present at the site (CDMG 1994a; Kohler 2006), and no mines are known to have existed within the proposed project boundaries (USGS 2008b). Many inactive mines and mineral prospects are hosted by metamorphic and intrusive basement rocks within 10 miles of the proposed project boundary, primarily in the Palen and Chuckwalla Mountains. These have produced a number of precious and base metals, including iron (magnetite) and pyrophyllite (CDMG 1994a). Minor gold, silver, copper and uranium prospects are located in the Palen Mountains northeast of the site. The Black Jack Mine in the northern McCoy Mountains about 16 miles northeast of the site is known for the most productive and most extensively worked manganese mine in the southern California. This manganese mine was active during war times and in the 1950s to produce several thousand tons of manganese. This area is within the approximately 1.4-square-mile surface area Ironwood Manganese District. Other mining areas, including the Blue Bird Mine area, St. John Mine area, and George Mine area are also located in the northern McCoy Mountains and have produced manganese, copper, and a small amount of silver and gold in the past (CDMG 1994a). Uranium has been claimed in the southern McCoy Mountains about 22 miles east of the site with reported past production by Caproci-Woock Groups (CDMG 1968). There are several other prospective or claim areas for minerals in the McCoy Mountains including manganese, copper, silver, gold, and uranium (USGS 2009). The Roosevelt and Rainbow group of mines in the Mule Mountain district, also known as the Hodges Mountain district that is located about 26 miles southeast of the site, have produced some gold and copper from the quartz veins in granitic rocks (CDMG 1998).

The nearest oil and gas fields are located more than 150 miles west of site in the Los Angeles Sedimentary basin (CDC 2001). The nearest geothermal field is located at Brawley just south of the Salton Sea in the Imperial Valley basin about 40 miles southwest of site (CDC 2000; CDC 2001).

Several gravel borrow pits are present along Interstate 10 (I-10) south of the site, and the presence of alluvial fan materials at the proposed project location means that the property could potentially be accessed and developed as a source of salable sand and gravel resources. During construction, the project owner may need or desire to move sand and gravel either off-site, or between the different units of the facility. Should this occur, the project owner would be required to comply with BLM regulations in 43 CFR Part 3600, which regulates the production and use of sand and gravel from public lands. Use of sand and gravel or other mineral materials within the boundaries of an authorized ROW is permitted; however, removal of these materials from an authorized ROW would require payment to the United States of the fair market value of those materials.

Paleontologic Resources

Staff has reviewed the paleontologic resources assessment in Section 5.9 of the AFC (Solar Millennium 2009a). Staff has also reviewed the paleontologic literature and records search conducted by NHMLA (McCleod, 2009); UCMP; and RCLIA (2009) for information regarding known fossil localities and stratigraphic unit sensitivity within the proposed project area. Site-specific information generated by the applicant for the PSPP was also reviewed (SWCA 2009).

Review of previous paleontological research conducted in the PSPP vicinity showed that the region is poorly understood. Very few comprehensive studies have taken place, and few finds have been reported to local museums. The information reviewed indicates there are no recorded fossil collection sites within the proposed project boundaries or within a one-mile radius. Three vertebrate fossil collection areas have been documented in the proposed project area within the same or similar sedimentary units which underlie the site. One location east-southeast of the site between I-10 and Ford Dry Lake contained fossil remains of a pocket mouse. Another site northwest of the proposed project site in the northern Chuckwalla Valley yielded fossil remains of tortoise, horse, camel, and llama.

More recently, there has been an influx of paleontological information associated with the large energy projects proposed and under construction in the Chuckwalla Valley and the Palo Verde Mesa. Originally, the low number of finds in the project vicinity was interpreted as an indication of low sensitivity. However, paleontological field survey and construction monitoring associated with these large projects in the last decade have consistently identified significant paleontological resources in both surface and buried contexts. For example, during construction of the Genesis Solar Energy Project, paleontological monitors have found multiple vertebrate fossils, primarily tortoise carapace and bones (BLM 2012).

Initial studies conducted for the nearby Desert Sunlight Project originally deemed the site to be of low probability for encountering vertebrate fossils (low sensitivity). However since the recent breaking of ground, several specimens (identifiable fragments or individual bones) and numerous unidentifiable fragments have been found. The identifiable species include Smilodon (carpels, metacarpels, and distal end of ulna), a phalange of an undetermined cervidae sp., a camilid, tortoise, and several partials of small mammals and rodentia. The results of these recent studies suggest that the Chuckwalla Valley is more paleontologically sensitive than originally believed (BLM 2012).

Multiple studies have identified paleosols (old soil horizons) within the Quaternary alluvium of the region. These horizons formed slowly through mechanical and chemical erosion during wetter periods in the Late Pleistocene of the Colorado Desert. These conditions are very favorable for the preservation of fossils, especially short-lived species such as rodents. These paleosols have been identified below desert pavement in the southern Chuckwalla Valley, south of Interstate 10 near State Route 177 (BLM 2012), and at the Rio Mesa Solar Energy Generating Facility (Rio Mesa). In the paleontological assessment of the proposed Rio Mesa project it was found that at least two paleosols occur between six and seven feet below the modern ground surface of the Palo Verde Mesa (Stewart 2012).

Near-surface geology beneath the PSEGS site consists primarily of Quaternary alluvium, eolian and lacustrine sediments which increases in age with depth from Holocene at the surface to Pleistocene and older at depth (CDMG 1967; USGS 1989; USGS 1990; USGS 2006). Coarse-grained sediments grade laterally and are interbedded with lakebed deposits of similar ages. Pleistocene age older alluvium, which is exposed along the southwestern boundary of the site, underlies younger alluvium and lacustrine sediments. Older alluvium would likely be buried at progressively deeper depths beneath Holocene sediments to the northeast across the site.

The results of a site-specific comprehensive surficial field survey recorded one non-significant fossil occurrence that yielded a non-diagnostic vertebrate material within the project limits (Solar Millennium 2009b). The specimen was discovered on the ground surface and was considered to have been *ex-situ* (i.e. removed from its original place of fossilization) and transported an unknown distance and re-deposited on top of alluvial sediments (Solar Millennium 2009a). As a result of this interpretation, the fossil resource discovered on the surface within the limits of the project was not considered significant. However, recent paleontological research in the site region suggests that “specimens that might be regarded as *ex-situ* have not moved laterally and only moved a slight amount vertically.” (Stewart 2012). This alternative interpretation would indicate the likely presence of fossils beneath the location where the specimen was recovered.

The Riverside County Transportation and Land Management Agency (TLMA) has produced a paleontological sensitivity map of the county (RCLIS 2009). The mapping indicates that areas underlain by Playa Lake, eolian and younger alluvial deposits within and around the Palen Dry Lake basin have a high paleontological sensitivity rating. Younger alluvium upslope from the lake bed has a low sensitivity rating, and older alluvium is assigned an undetermined sensitivity rating, according to the TLMA.

Based on the above information, the paleontological resource sensitivity of undisturbed Quaternary alluvium and lacustrine sediments varies from low at depths less than 1.5 feet to high at depths below 1.5 feet. Since the depth to Pleistocene age sediments beneath Holocene deposits is unknown, staff concludes that all sediments beneath disturbed ground should initially be treated as highly sensitive. Where these units are mapped at the surface or may be present near the surface adjacent to these mapped areas, specifically along the northern and southern borders of the site, paleontological monitoring should be conducted during any excavation activity. Since the depth to Pleistocene age alluvial and lacustrine deposits is undetermined at present for the remainder of the site, any excavations that penetrate below 1.5 feet of the existing ground surface should be treated as having a high potential for impacting significant paleontological resources and would require paleontological monitoring. This depth is based on observations of possible older alluvium encountered in excavations advanced for the geomorphic reconnaissance report (Solar Millennium 2009a). This depth would likely increase from the northern and southern boundaries towards the center of the proposed PSEGS site. After subsurface field exploration, and monitoring of grading and trenching activities during proposed construction of the site, a qualified professional paleontologist could determine the appropriate depth above which the coarse and fine grained soils are Holocene in age, have a low sensitivity, and low potential for adverse impacts on paleontological resources. Where pylons are driven into soils with high sensitivity, the potential for adverse impacts on paleontological resources is undetermined.

These conclusions are based on SVP criteria, the Paleontologic Resource Assessments in the AFC (Solar Millennium 2009a), and the independent records searches and paleontologic review provided by McLeod (2009), the UCMP (2009); and RCLIA (2009). Existing Conditions of Certification **PAL-1** to **PAL-8** are designed to mitigate paleontologic resource impacts resulting from conventional excavation operations, as discussed above, to less than significant levels. These conditions would essentially require a worker education program in conjunction with the monitoring of earthwork activities by the PRS assigned to the project.

In areas where heliostats are to be supported by pylons that are vibro-inserted or pre-augured and vibro-inserted, adverse impacts to paleontological resources are likely to occur.

In order to adequately mitigate for the potential impacts to paleontological resources in the subsurface soils where heliostat pylons are proposed, a subsurface paleontological characterization must be performed in accordance with Condition of Certification **PAL-9**. The characterization will allow for the refinement of various mitigation options including fossil recovery and data collection, avoidance, and modifications of post insertion to be implemented as appropriate to ensure significant impacts are mitigated.

CONSTRUCTION IMPACTS AND MITIGATION

The design-level geotechnical evaluation, required for the project by the CBC (2010) and existing Condition of Certification **GEO-1,** should provide standard engineering design recommendations for mitigation of earthquake ground shaking; excessive settlement due to dynamic compaction and hydrocompaction; and potentially expansive soils.

Construction of the proposed project would directly remove approximately 3,794 acres from potential use for sand and gravel production under BLM's salable mineral program. In general, sand and gravel resources are widely available throughout the region. The primary consideration in the economic viability of sand and gravel operations is the transportation cost, which is driven by the proximity of the operation to its point of use. Although there is likely to be widespread development in the Chuckwalla Valley that would require sand and gravel resources, the site represents a small fraction of the total sand and gravel resource available within the valley such that removal of the 3,794-acre area from potential production is not expected to have any significant impact on potential future development. As a result, the PSEGS would not impact any current or reasonably foreseeable development of geologic resources. However, during construction, the project owner may need or desire to move sand and gravel either off-site or between the different units of the facility. Should this occur, the project owner would be required to comply with BLM regulations in 43 CFR Part 3600, which regulates the production and use of sand and gravel from public lands. Use of sand and gravel or other mineral materials within the boundaries of an authorized ROW is permitted; however, removal of these materials from an authorized ROW would require payment to the United States of the fair market value of those materials.

The proposed project would not have any direct or indirect impact on the production of locatable or leasable minerals outside of the proposed project boundaries. Although mineral occurrences have been claimed in the vicinity of the PSEGS site, there are no indications that these could become economic commercial operations. If they become economic operations, the existence of the proposed facility is not expected to interfere with the ability of the claimant to access those minerals. The only potential conflict would occur if the claimant or another person locates a new claim within the project boundaries. This could potentially occur, as the proposed project location has not been withdrawn from mineral entry. The potential for this scenario is expected to be low. If it did occur, conflicts between the surface use of the land for solar energy production and access to the subsurface minerals would be addressed in accordance with federal and Riverside County land use regulations. Therefore, the PSEGS would not impact any current or reasonably foreseeable development of mineral resources.

Significant paleontologic resources have been documented in the same or similar older alluvium deposits that are present in the general area of the project. Existing studies indicate the soils beneath the solar field are likely to contain Pleistocene age vertebrate fossils. Construction of the proposed project will include grading, foundation excavation, utility trenching, pylon insertion and possibly drilled shafts. Staff considers the probability of encountering paleontologic resources to be generally high on portions of the site based on the soils profile, SVP assessment criteria, and the near surface occurrence of the sensitive geologic units. The potential for encountering fossils hosted in Quaternary alluvium will increase with the depth of cut. Excavations for ancillary facilities and new pipelines and on-site excavations that penetrate surficial Holocene age alluvium will have a higher probability of encountering potentially high sensitivity materials, although sensitive materials could occur nearer the surface. The proposed mitigation cannot avoid or reduce fossil disturbance associated with pylon insertion or drilled shaft foundations. Conditions of Certification **PAL-1** to **PAL-8** are designed to mitigate any paleontologic resource impacts, as discussed above, to a less than significant level. Conditions of Certification **PAL-1** to **PAL-8** are designed to mitigate potential impacts to paleontologic resources to less than significant levels in areas where conventional excavation operations occur. These Conditions of Certification essentially require a worker education program in conjunction with the monitoring of earthwork activities by a qualified professional paleontologist (paleontologic resource specialist [PRS]). In addition, the applicant proposed paleontological monitoring of geotechnical borings within the solar field in an attempt to assist with the evaluation of the paleontological sensitivity where pylons will be inserted. Staff agrees that the monitoring of the borings should be conducted and could be useful in further delineating sensitive paleontological resources. Staff has added the suggested language for additional monitoring to Condition of Certification **PAL-5**. Staff points out however, that this monitoring would not allow for mitigation of impacts if it is found there are extensive sensitive resources in the areas where pylons will be inserted.

However, with implementation of **PAL-9**, and if the CPM determines significant paleontological resources are statistically significant at the site, the project owner will be required to implement one of the following mitigation measures:

A. Provide an assessment of how avoidance of the sensitive geologic units containing significant paleontological resources may be accomplished so impacts can be minimized.

B. Where avoidance cannot be achieved in all or part of the solar field the Project Owner shall provide an assessment of alternative foundations design and construction methods that may be used in the areas where significant paleontological resources are identified.

C. Where avoidance and alternative foundation design and construction cannot be accomplished the project owner shall conduct additional excavation and collection of paleontological resources for curation such that the collection adequately assesses the scientific significance of the site and preserves a cross-section of material that can be used for future analysis and the benefit of public appreciation.

If the results of the subsurface paleontological characterization show that there are no or limited significant paleontological resources in the solar field where pylons will be driven, the CPM may find that monitoring and mitigation in accordance with Condition of Certification **PAL-1** through **PAL-8** are adequate to ensure no significant impacts would occur.

Earthwork would be halted any time potential fossils are recognized by either the paleontologist or the worker. For finds deemed significant by the PRS, earthwork cannot restart until all fossils in that strata, including those below the design depth of excavation, are collected. When properly implemented, the Conditions of Certification would yield a net gain to the science of paleontology since fossils that would not otherwise have been discovered can be collected, identified, studied, and properly curated. A PRS would be retained, for the project by the project owner, to produce a monitoring and mitigation plan, conduct the worker training, and oversee the monitoring.

During the excavation monitoring, the PRS can and often does petition the Energy Commission for a change in the monitoring protocol. Most commonly, this is a request for less monitoring after sufficient monitoring has been performed to ascertain that there is little chance of finding significant fossils. In other cases, the PRS can propose increased monitoring due to unexpected fossil discoveries or in response to repeated out-of-compliance incidents by the earthwork contractor. In the case of the PSEGS site, the PRS would determine an appropriate depth above which undisturbed alluvial deposits are Holocene in age, have a low paleontologic sensitivity, and have little chance of containing significant fossils. The PRS could then recommend decreased monitoring for excavations above that depth. Paleontologic sensitivity of Pleistocene age sediments below the determined depth would remain high and would require continued monitoring. Based upon the literature and archives search, field surveys, and compliance documentation for the proposed PSEGS, the project owner has proposed monitoring and mitigation measures to be followed during the excavation stage of project construction. Staff believes that the facility can be designed and constructed to minimize the effect of geologic hazards and impacts to potential paleontologic resources at the site during project design life.

OPERATION IMPACTS AND MITIGATION

Operation of the proposed project should not have any adverse impact on geologic, mineralogic, or paleontologic resources because significant additional ground disturbance would not occur. Since the CBC (2010) requires that the facility be designed to withstand strong ground shaking, impacts due to seismic events should not significantly impact the structural integrity or operation of the facility.

NON-OPERATION AND FACILITY CLOSURE IMPACTS AND MITIGATION

The future non-operation and facility closure of the project should not negatively affect geologic, mineralogic, or paleontologic resources since the ground disturbed during plant facility closure would have been already disturbed, and mitigated as required, during construction and operation of the project.

CUMULATIVE IMPACTS

The **EXECUTIVE SUMMARY** section provides information on the potential cumulative solar and other development projects in the project area. Together, these existing, proposed and potential projects comprise the cumulative scenario which forms the basis of the cumulative impact analysis for the proposed project. In summary, these projects are:

- Existing projects on BLM, State, and private lands, as shown on **Executive Summary Attachment A – Figure 1** and in **Executive Summary Attachment A – Table 1.** Forseeable renewable energy projects on BLM, state, and private lands, as shown on **Executive Summary Attachment A – Figure 1** and in **Executive Summary Attachment A – Table 2**. Although not all of those projects are expected to complete the environmental review processes, or be funded and constructed, the list is indicative of the large number of renewable projects currently proposed in California.
- Projects submitted and on-hold as shown on **Executive Summary Attachment A – Figure 1** and **Executive Summary Attachment A –Table 3** presents projects submitted but that are on hold.

These projects are defined within a geographic area that has been identified by the Energy Commission and BLM as covering an area large enough to provide a reasonable basis for evaluating cumulative impacts for all resource elements or environmental parameters. Most of these projects have, are, or will be required to undergo their own independent environmental review under CEQA and/or NEPA. Even if the cumulative projects described in the **Executive Summary** have not yet completed the required environmental processes, they were considered in this cumulative impact analysis.

GEOGRAPHIC SCOPE OF ANALYSIS

The geographic extent of potential impact to geologic, mineralogic, and paleontologic resources would be generally limited to the PSEGS site. Potential cumulative effects, as they pertain to geologic hazards, are essentially limited to regional subsidence due to ground water withdrawal. Impacts associated with strong ground shaking and dynamic compaction are not cumulative in nature and would not add to potential cumulative impacts to the facility.

EFFECTS OF PAST AND PRESENT PROJECTS

Historic ground water withdrawals on the order of 48,000 ac-ft/yr and associated impacts to ground water levels did not result in any documented subsidence in the proposed project area even with increases in effective stress on clay layers present at depth. During operation. the proposed PSEGS would consume approximately 201 ac-ft/yr, which is not expected to significantly affect regional subsidence in the geographic area. Additional groundwater information is contained in the **SOIL AND WATER RESOURCES** section.

Paleontologic resources have been documented in the general area of the project. As the value of paleontologic resources is associated with their discovery within a specific geologic host unit, the potential impacts to paleontologic resources due to conventional excavation construction activities will be mitigated as required by Conditions of Certification **PAL-1** through **PAL-8**. Implementation of these conditions should result in a net gain to the science of paleontology by allowing fossils that would not otherwise have been found to be recovered, identified, studied, and preserved. Cumulative impacts, in consideration with other nearby similar projects, should be either neutral (no fossils encountered) or positive (fossils encountered, preserved, and identified). Construction associated with past and present projects could add to fossil discoveries which would enhance our understanding of the prehistoric climate, geology, and geographic setting of the region for the benefit of current and future generations. The potential impacts to paleontologic resources in areas where heliostat pylons are proposed for insertion, construction activities will be mitigated as required by Condition of Certification **PAL-9**. Similar to recovery of fossils in the course of conventional site construction, this characterization effort would yield recovery of fossils representative of those that would be damaged from pylon insertion.

EFFECTS OF REASONABLY FORESEEABLE FUTURE PROJECTS

Foreseeable Projects in the Project Area

Several future foreseeable projects identified in **Executive Summary Attachment A – Table 2** are located within the Chuckwalla Valley. Such projects would most likely include ground water pumping of similar magnitude to the PSEGS; however, the combined effect of these projects would still result in much less than the historic rate of 48,000 ac-ft/yr, which did not result in any documented regional subsidence, such that significant impacts to regional subsidence would not be expected. Therefore, there would be no significant cumulative contribution to regional subsidence from foreseeable renewable projects in the Chuckwalla Valley. Additional information on ground water withdrawal is contained in the **SOIL AND WATER RESOURCES** section.

Foreseeable Renewable Projects in the California Desert

Several future foreseeable renewable projects in the California Desert, as shown in **Executive Summary Attachment A –Table 2**, would be located within the Chuckwalla Valley. Such projects would most likely include ground water pumping of similar magnitude to the PSEGS; however, the combined effect of these projects would still result in much less than the historic rate of 48,000 ac-ft/yr, which did not result in any documented regional subsidence, such that significant impacts to regional subsidence would not be expected. Therefore, there would be no significant cumulative contribution to regional subsidence from foreseeable renewable projects in the California Desert. Additional information on ground water withdrawal is contained in the **SOIL AND WATER RESOURCES** section.

CONTRIBUTION OF THE PALEN SOLAR ELECTRIC GENERATING SYSTEM TO CUMULATIVE ANALYSIS

Construction

The construction of the PSEGS is not expected to require any significant amount of ground water pumping such that impacts to regional subsidence are not expected.

Sand and gravel resources are present at the site and could be used during construction to minimize importation of such materials from other commercially available sources in the area, thereby minimizing impacts to current commercially available sand and gravel resources. In addition, sand and gravel resources are present throughout the regional area. Therefore, construction of the PSEGS would not impact any reasonably foreseeable development of sand and gravel resources.

The construction of the PSEGS would include excavation and grading at the site. Proper monitoring of excavations at the proposed PSEGS facility during construction could result in fossil discoveries, which would enhance our understanding of the prehistoric climate, geology, and geographic setting of the region for the benefit of current and future generations.

As stated in the PSPP AFC, “the destruction of fossils as a result of human-caused ground disturbance has a significant cumulative impact, as it makes biological records of ancient life permanently unavailable for study by scientists… Construction of the PSPP has the potential to result in the destruction of sub-surface paleontological resources via breakage and crushing related to ground-disturbing activities during grading for the proposed facilities (e.g., solar field, power block, ancillary facilities, drainage channels, and access road) [and from the installation of 140,000 heliostat pylons]. Project ground disturbance and terrain modification…of sediments, has the potential to adversely affect an unknown quantity of fossils that may occur on or underneath the surface in areas containing paleontologically sensitive geologic units.” (Solar Millennium 2009a).

Potential impacts to paleontologic resources would be mitigated through worker training and monitoring by qualified paleontologists, as required by Conditions of Certification, **PAL-1** through **PAL-8** in areas where soils are exposed by conventional excavation operations.

Conversely, where heliostat pylons are vibro-inserted into soils with high paleontological sensitivity, fossils will be destroyed with no opportunity for discovery or recovery.

Under the site's current classification of paleontological sensitivity, it must be concluded that significant adverse impacts to paleontological resources would result from the proposed method of pylon insertion. Similar to recovery of fossils in the course of conventional site construction, implementation of Condition of Certification **PAL-9** would yield recovery of fossils representative of those that would be damaged from pylon insertion.

Operation

The operation of the PSEGS is expected to result in increased annual ground water pumping in the geographic area, from the current 2,000 ac-ft/yr to approximately 2,200 ac-ft/yr. Historic ground water withdrawals on the order of 48,000 ac-ft/yr did not result in any documented subsidence in the proposed project area. Since operation of the PSEGS would only contribute a minor amount of additional ground water withdrawal to the overall amount in the Chuckwalla Valley and since this cumulative amount is only a fraction of historic pumping levels that did not result in any documented subsidence, operation of the PSEGS is not expected to impact regional subsidence in the Chuckwalla Valley.

Operation of the PSEGS is not expected to require any significant excavation or grading such that impacts to geologic, mineralogic, and paleontologic resources are expected.

Non-operation and Facility Closure

Non-operation and facility closure of the PSEGS is not expected to require any significant amount of ground water pumping such that impacts to regional subsidence are not expected. In addition, potential sand and gravel resources would become available again following the facility closure.

Closure of the project should not negatively affect geologic, mineralogic, or paleontologic resources since the ground disturbed during facility closure would have been already disturbed, and mitigated as required, during construction and operation of the project. As a result, facility closure of the PSEGS would not contribute to cumulative impacts to geologic, mineralogic, and paleontologic resources, but rather would make existing sand and gravel resources available, and would allow for potential procurement of paleontologic resources that would otherwise remain unknown.

OVERALL CONCLUSION

Based on its independent research and review, Energy Commission staff believes that the potential is low for significant adverse impacts to the proposed project from geologic hazards during its design life and to potential geologic and mineralogic resources from the construction, operation, and closure of the proposed project.

The proposed project area is currently not used for mineral production, nor is it under claim, lease, or permit for the production of locatable, leasable, or salable minerals. Sand and gravel resources are present at the site and could potentially be a source of salable resources; however, such materials are present throughout the regional area such that the PSEGS should not have a significant impact on the availability of such resources. There are no other known viable geologic or mineralogic resources at the PSEGS site.

Potential impacts to paleontologic resources would be mitigated through worker training and monitoring by qualified paleontologists, as required by Conditions of Certification, **PAL-1** through **PAL-8** in areas where soils are exposed by conventional excavation operations and by **PAL-9** in areas where pylons will be vibro-inserted.

COMPLIANCE WITH LORS

Federal, state, or local/county laws, ordinances, regulations, and standards applicable to the proposed project were detailed in **Geology and Paleontology Table 1**. Staff anticipates that the project would be able to comply with most applicable LORS. However, as proposed, the project would not comply with “Measures for Assessment and Mitigation of Adverse Impacts to Non-Renewable Paleontological Resources: Standard Procedures” as developed by the Society of Vertebrate Paleontologists. These Measures paraphrase Section 6302 of the Paleontological Resources Preservation Act (PRPA) which mandates that federal agencies "*shall manage and protect paleontological resources on Federal land using scientific principles and expertise.*" In addition, as proposed, the project would not comply with Bureau of Land Management (BLM) Instructional Memorandum 2008-009 which requires the Potential Fossil Yield Classification (PFYC) system to be used to classify paleontological resource potential on public lands in order to assess possible resource impacts and mitigation needs for Federal actions involving surface disturbance, land tenure adjustments, and land-use planning. Memorandum 2008-009 also provides up-to-date methodologies for assessing paleontological sensitivity and management guidelines for paleontological resources on lands managed by the Bureau of Land Management

NOTEWORTHY PUBLIC BENEFITS

The science of paleontology is advanced by the discovery, study and curation of new fossils. These fossils can be significant if they represent a new species, verify a known species in a new location and/or if they include parts of similar specimens that had not previously been found preserved. In general, most fossil discoveries are the result of excavations, either purposeful in known or suspected fossil localities or as the result of excavations made during earthwork for civil improvements or mineral extraction. Proper monitoring of excavations at the proposed PSEGS facility, in accordance with an approved Paleontological Monitoring and Mitigation Plan, could result in fossil discoveries which would enhance our understanding of the prehistoric fossil record, or the climate, geology, and geographic setting of the region for the benefit of current and future generations. In addition, subsurface paleontological characterization of site soils could also yield beneficial information and become the basis of significance determination of adverse impact in areas penetrated by heliostat pylons.

RESPONSE TO COMMENTS

STATE OF CALIFORNIA, ENERGY RESOURCES CONSERVATION AND DEVELOPMENT COMMISSION/BASIN AND RANGE WATCH, KEVIN EMMERICH AND LAURA CUNNINGHAM, COMMENTS ON THE PRELIMINARY STAFF ASSESSMENT, TN # 200078, JULY 28, 2013:

Comment: Potentially sensitive and valuable paleontological resources have been discovered at the Palen project site. Heliostat foundation construction consisting of pre-drilling and vibratory pedestal insertion could destroy all fossils encountered where installation takes place in the fossil bearing sediments.

Pre-drilling involves rotating and boring a solid steel drill auger into the ground. This construction method would crush or break any fossils that might be present. A Supplemental Paleontological Resources Delineation Report should be prepared before approval. In it should be maps and drawings of all facilities and ground disturbance. A monitoring and sampling plan should be made. If significant fossils are found, a plan should be given for how construction will be halted. Potentially sensitive and valuable paleontological resources have been discovered at the Palen project site. Heliostat foundation construction consisting of pre-drilling and vibratory pedestal insertion could destroy all fossils encountered where installation takes place in the fossil bearing sediments.

Staff Response: Energy Commission staff requested that the applicant provide a Paleontological Resources Delineation Plan capable of addressing the issues identified by staff in the PSA and summarized in the Basin and Range Watch comment above. The applicant submitted a “Paleontological Resources Characterization” as Data Response DR 76-1. The information presented in DR 76-1 did not address all of the items requested in the Data Request and the submission was not sufficiently compelling to refute either the data presented in the PSA or new information gleaned from discussions with BLM staff regarding paleontological resources discovered at other solar project sites in the area. This information provides further support that the site likely contains areas of high paleontological sensitivity.

CONCLUSIONS

The project owner would comply with applicable LORS, provided that the existing Conditions of Certification are implemented and followed. The design and construction of the project, as amended, should have no adverse impact with respect to geologic hazards, or geologic and mineralogic, resources.

With implementation of **PAL-9**, and if the CPM determines significant paleontological resources are statistically significant at the site, the project owner may be required to implement one of the following mitigation measures:

D. Provide an assessment of how avoidance of the sensitive geologic units containing significant paleontological resources may be accomplished so impacts can be minimized.

E. Where avoidance cannot be achieved in all or part of the solar field the Project Owner shall provide an assessment of alternative foundations design and construction methods that may be used in the areas where significant paleontological resources are identified.

F. Where avoidance and alternative foundation design and construction cannot be accomplished the project owner shall conduct additional excavation and collection of paleontological resources for curation such that the collection adequately assesses the scientific significance of the site and preserves a cross-section of material that can be used for future analysis and the benefit of public appreciation.

If the results of the subsurface paleontological characterization show that there are no or limited significant paleontological resources in the solar field where pylons will be driven, the CPM may find that monitoring and mitigation in accordance with Condition of Certification **PAL-1** through **PAL-8** are adequate to ensure no significant impacts would occur.

Staff proposes to ensure compliance with LORS through the adoption of the conditions of certification listed below.

CONDITIONS OF CERTIFICATION

Staff has proposed modifications to the **Geology and Paleontology** Conditions of Certification as shown below. (**Note:** Deleted text is in ~~strikethrough~~; new text is **bold and underlined**)

GEO-1 The Soils Engineering Report required by Section 180~~2A~~**3** of the 20~~07~~**10** CBC should specifically include laboratory test data, associated geotechnical engineering analyses, and a thorough discussion of potential hydro-compaction or dynamic compaction; the presence of expansive clay soils; and the presence of corrosive soils. The report should also include recommendations for ground improvement and/or foundation systems necessary to mitigate these potential geologic hazards, if present.

Verification: The project owner shall include in the application for a grading permit a copy of the Soils Engineering Report which addresses the potential for liquefaction; settlement due to compressible soils, ground water withdrawal, hydro-compaction, or dynamic compaction; and the possible presence of expansive clay soils, and a summary of how the results of the analyses were incorporated into the project foundation and grading plan design for review and comment by the Chief Building Official (CBO). A copy of the Soils Engineering Report, application for grading permit and any comments by the CBO are to be provided to the CPM at least 30 days prior to grading.

PAL-1 The project owner shall provide the compliance project manager (CPM) with the resume and qualifications of its paleontological resource specialist (PRS) for review and approval. If the approved PRS is replaced prior to completion of project mitigation and submittal of the Paleontological Resources Report, the project owner shall obtain CPM approval of the replacement PRS. The project owner shall keep resumes on file for qualified paleontological resource monitors (PRMs). If a PRM is replaced, the resume of the replacement PRM shall also be provided to the CPM.

The PRS resume shall include the names and phone numbers of references. The resume shall also demonstrate to the satisfaction of the CPM the appropriate education and experience to accomplish the required paleontological resource tasks.

As determined by the CPM, the PRS shall meet the minimum qualifications for a vertebrate paleontologist as described in the Society of Vertebrate Paleontology (SVP) guidelines of 1995. The experience of the PRS shall include the following:

1. Institutional affiliations, appropriate credentials, and college degree;
2. Ability to recognize and collect fossils in the field;
3. Local geological and biostratigraphic expertise;
4. Proficiency in identifying vertebrate and invertebrate fossils; and
5. At least three years of paleontological resource mitigation and field experience in California and at least one year of experience leading paleontological resource mitigation and field activities.

The project owner shall ensure that the PRS obtains qualified paleontological resource monitors to monitor as he or she deems necessary on the project. Paleontologic resource monitors (PRMs) shall have the equivalent of the following qualifications:

- BS or BA degree in geology or paleontology and one year of experience monitoring in California; or
- AS or AA in geology, paleontology, or biology and four years' experience monitoring in California; or
- Enrollment in upper division classes pursuing a degree in the fields of geology or paleontology and two years of monitoring experience in California.

Verification:

(1) At least 60 days prior to the start of ground disturbance, the project owner shall submit a resume and statement of availability of its designated PRS for on-site work.

(2) At least 20 days prior to ground disturbance, the PRS or project owner shall provide a letter with resumes naming anticipated monitors for the project, stating that the identified monitors meet the minimum qualifications for paleontological resource monitoring required by the condition. If additional monitors are obtained during the project, the PRS shall provide additional letters and resumes to the CPM. The letter shall be provided to the CPM no later than one week prior to the monitor's beginning on-site duties.

(3) Prior to the termination or release of a PRS, the project owner shall submit the resume of the proposed new PRS to the CPM for review and approval.

PAL-2 The project owner shall provide to the PRS and the CPM, for approval, maps and drawings showing the footprint of the power plant, construction lay-down areas, and all related facilities. Maps shall identify all areas of the project where ground disturbance is anticipated. If the PRS requests enlargements or strip maps for linear facility routes, the project owner shall provide copies to the PRS and CPM. The site grading plan and plan and profile drawings for the utility lines would be acceptable for this purpose. The plan drawings should show the location, depth, and extent of all ground disturbances and be at a scale between 1 inch = 40 feet and 1 inch = 100 feet. If the footprint of the project or its linear facilities changes, the project owner shall provide maps and drawings reflecting those changes to the PRS and CPM.

If construction of the project proceeds in phases, maps and drawings may be submitted prior to the start of each phase. A letter identifying the proposed schedule of each project phase shall be provided to the PRS and CPM. Before work commences on affected phases, the project owner shall notify the PRS and CPM of any construction phase scheduling changes.

At a minimum, the project owner shall ensure that the PRS or PRM consults weekly with the project superintendent or construction field manager to confirm area(s) to be worked the following week and until ground disturbance is completed.

Verification:

(1) At least 30 days prior to the start of ground disturbance, the project owner shall provide the maps and drawings to the PRS and CPM.

(2) If there are changes to the footprint of the project, revised maps and drawings shall be provided to the PRS and CPM at least 15 days prior to the start of ground disturbance.

(3) If there are changes to the scheduling of the construction phases, the project owner shall submit a letter to the CPM within 5 days of identifying the changes.

PAL-3 The project owner shall ensure that the PRS prepares, and the project owner submits to the CPM for review and approval, a paleontological resources monitoring and mitigation plan (PRMMP) to identify general and specific measures to minimize potential impacts to significant paleontological resources. Approval of the PRMMP by the CPM shall occur prior to any ground disturbance. The PRMMP shall function as the formal guide for monitoring, collecting, and sampling activities and may be modified with CPM approval. This document shall be used as the basis of discussion when on-site decisions or changes are proposed. Copies of the PRMMP shall reside with the PRS, each monitor, the project owner’s on-site manager, and the CPM.

The PRMMP shall be developed in accordance with the guidelines of the Society of Vertebrate Paleontology (SVP 1995) and shall include, but not be limited, to the following:

1. Assurance that the performance and sequence of project-related tasks, such as any literature searches, pre-construction surveys, worker environmental training, fieldwork, flagging or staking, construction monitoring, mapping and data recovery, fossil preparation and collection, identification and inventory, preparation of final reports, and transmittal of materials for curation will be performed according to PRMMP procedures;

2. Identification of the person(s) expected to assist with each of the tasks identified within the PRMMP and the conditions of certification;

3. A thorough discussion of the anticipated geologic units expected to be encountered, the location and depth of the units relative to the project when known, and the known sensitivity of those units based on the occurrence of fossils either in that unit or in correlative units;

4. An explanation of why, how, and how much sampling is expected to take place and in what units. Include descriptions of different sampling procedures that shall be used for fine-grained and coarse-grained units;

5. A discussion of the locations of where the monitoring of project construction activities is deemed necessary, and a proposed plan for monitoring and sampling;

6. A discussion of procedures to be followed in the event of a significant fossil discovery, halting construction, resuming construction, and how notifications will be performed;

7. A discussion of equipment and supplies necessary for collection of fossil materials and any specialized equipment needed to prepare, remove, load, transport, and analyze large-sized fossils or extensive fossil deposits;

8. Procedures for inventory, preparation, and delivery for curation into a retrievable storage collection in a public repository or museum, which meet the Society of Vertebrate Paleontology's standards and requirements for the curation of paleontological resources;

9. Identification of the institution that has agreed to receive data and fossil materials collected, requirements or specifications for materials delivered for curation and how they will be met, and the name and phone number of the contact person at the institution; and

10. A copy of the paleontological Conditions of Certification.

Verification: At least 30 days prior to ground disturbance, the project owner shall provide a copy of the PRMMP to the CPM. The PRMMP shall include an affidavit of authorship by the PRS and acceptance of the PRMMP by the project owner evidenced by a signature.

PAL-4 Prior to ground disturbance and for the duration of construction activities involving ground disturbance, the project owner and the PRS shall prepare and conduct weekly CPM-approved training for the following workers: project managers, construction supervisors, foremen, and general workers involved with or who operate ground-disturbing equipment or tools. Workers shall not excavate in sensitive units prior to receiving CPM-approved worker training. Worker training shall consist of an initial in-person PRS training or may utilize a CPM-approved video or other presentation format during the project kick off for those mentioned above. Following initial training, a CPM-approved video or other approved training presentation/materials, or in-person training may be used for new employees. The training program may be combined with other training programs prepared for cultural and biological resources, hazardous materials, or other areas of interest or concern. No ground disturbance shall occur prior to CPM approval of the Worker Environmental Awareness Program (WEAP), unless specifically approved by the CPM.

The WEAP shall address the possibility of encountering paleontological resources in the field, the sensitivity and importance of these resources, and legal obligations to preserve and protect those resources.

The training shall include:

1. A discussion of applicable laws and penalties under the law;
2. Good quality photographs or physical examples of vertebrate fossils for project sites containing units of high paleontologic sensitivity;
3. Information that the PRS or PRM has the authority to halt or redirect construction in the event of a discovery or unanticipated impact to a paleontological resource;
4. Instruction that employees are to halt or redirect work in the vicinity of a find and to contact their supervisor and the PRS or PRM;
5. An informational brochure that identifies reporting procedures in the event of a discovery;
6. A WEAP certification of completion form signed by each worker indicating that he/she has received the training; and
7. A sticker that shall be placed on hard hats indicating that environmental training has been completed.

<u>Verification:</u>

(1) At least 30 days prior to ground disturbance, the project owner shall submit the proposed WEAP, including the brochure, with the set of reporting procedures for workers to follow.

(2) At least 30 days prior to ground disturbance, the project owner shall submit the training program presentation/materials to the CPM for approval if the project owner is planning to use a presentation format other than an in-person trainer for training.

(3) If the owner requests an alternate paleontological trainer, the resume and qualifications of the trainer shall be submitted to the CPM for review and approval prior to installation of an alternate trainer. Alternate trainers shall not conduct training prior to CPM authorization.

(4) In the monthly compliance report (MCR), the project owner shall provide copies of the WEAP certification of completion forms with the names of those trained and the trainer or type of training (in-person or other approved format) offered that month. The MCR shall also include a running total of all persons who have completed the training to date.

PAL-5 The project owner shall ensure that the PRS and PRM(s) monitor consistent with the PRMMP all construction-related grading, excavation, trenching, and augering in areas where potential fossil-bearing materials have been identified, both at the site and along any constructed linear facilities associated with the project. In the event that the PRS determines full-time monitoring is not necessary in locations that were identified as potentially fossil bearing in the PRMMP, the project owner shall notify and seek the concurrence of the CPM.

<u>In addition to the monitoring activities above, the PRS shall monitor, consistent with the PRMMP, at least twenty (20) of the borings performed as part of the final geotechnical evaluation of the subsurface properties within the solar fields.</u>

The project owner shall ensure that the PRS and PRM(s) have the authority to halt or redirect construction if paleontological resources are encountered. The project owner shall ensure that there is no interference with monitoring activities unless directed by the PRS. Monitoring activities shall be conducted as follows:

1. Any change of monitoring from the accepted schedule in the PRMMP shall be proposed in a letter or email from the PRS and the project owner to the CPM prior to the change in monitoring and will be included in the monthly compliance report. The letter or email shall include the justification for the change in monitoring and be submitted to the CPM for review and approval.

2. The project owner shall ensure that the PRM(s) keep a daily monitoring log of paleontological resource activities. The PRS may informally discuss paleontological resource monitoring and mitigation activities with the CPM at any time.

3. The project owner shall ensure that the PRS notifies the CPM within 24 hours of the occurrence of any incidents of non-compliance with any paleontological resources conditions of certification. The PRS shall recommend corrective action to resolve the issues or achieve compliance with the conditions of certification.

4. For any significant paleontological resources encountered, either the project owner or the PRS shall notify the CPM within 24 hours, or Monday morning in the case of a weekend event, where construction has been halted because of a paleontological find.

The project owner shall ensure that the PRS prepares a summary of monitoring and other paleontological activities placed in the monthly compliance reports. The summary will include the name(s) of PRS or PRM(s) active during the month; general descriptions of training and monitored construction activities; and general locations of excavations, grading, and other activities. A section of the report shall include the geologic units or subunits encountered, descriptions of samplings within each unit, and a list of identified fossils. A final section of the report will address any issues or concerns about the project relating to paleontologic monitoring, including any incidents of non-compliance or any changes to the monitoring plan that have been approved by the CPM. If no monitoring took place during the month, the report shall include an explanation in the summary as to why monitoring was not conducted.

Verification: The project owner shall ensure that the PRS submits the summary of monitoring and paleontological activities in the MCR. When feasible, the CPM shall be notified 10 days in advance of any proposed changes in monitoring different from the plan identified in the PRMMP. If there is any unforeseen change in monitoring, the notice shall be given as soon as possible prior to implementation of the change.

PAL-6 The project owner, through the designated PRS, shall ensure that all components of the PRMMP are adequately performed including collection of fossil materials, preparation of fossil materials for analysis, analysis of fossils, identification and inventory of fossils, the preparation of fossils for curation, and the delivery for curation of all significant paleontological resource materials encountered and collected during project construction.

Verification: The project owner shall maintain in his/her compliance file copies of signed contracts or agreements with the designated PRS and other qualified research specialists. The project owner shall maintain these files for a period of three years after project completion and approval of the CPM-approved paleontological resource report (see Condition of Certification **PAL-7**). The project owner shall be responsible for paying any curation fees charged by the museum for fossils collected and curated as a result of paleontological mitigation. A copy of the letter of transmittal submitting the fossils to the curating institution shall be provided to the CPM.

PAL-7 The project owner shall ensure preparation of a Paleontological Resources Report (PRR) by the designated PRS. The PRR shall be prepared following completion of the ground-disturbing activities. The PRR shall include an analysis of the collected fossil materials and related information and submit it to the CPM for review and approval.

The report shall include, but ~~is~~ not be limited to, a description and inventory of recovered fossil materials; a map showing the location of paleontological resources encountered; determinations of sensitivity and significance; and the PRS' description of sensitivity and significance of those resources.

Verification: Within 90 days after completion of ground-disturbing activities, including landscaping, the project owner shall submit the PRR under confidential cover to the CPM.

PAL-8 The project owner, through the designated PRS, shall ensure that all components of the PRMMP are adequately performed, including collection of fossil material, preparation of fossil material for analysis, analysis of fossils, identification and inventory of fossils, preparation of fossils for curation, and delivery for curation of all significant paleontological resource materials encountered and collected during project construction. The project owner shall pay all curation fees charged by the museum for fossil material collected and curated as a result of paleontological mitigation. The project owner shall also provide the curator with documentation showing the project owner irrevocably and unconditionally donates, gives, and assigns permanent, absolute, and unconditional ownership of the fossil material.

Verification: Within 60 days after the submittal of the PRR, the project owner shall submit documentation to the CPM showing fees have been paid for curation and the owner relinquishes control and ownership of all fossil material.

PAL-9 The project owner shall prepare a paleontological characterization plan suitable to adequately assess the paleontological resources of the subsurface in the mirrored solar field area. The plan shall be provided to the compliance project manager (CPM) for review and approval. Following CPM approval of the plan, the project owner shall conduct the paleontological resources characterization of the subsurface in the solar field area. The characterization shall be conducted in accordance with the Bureau of Land Management (BLM) "Guidelines for Assessment and Mitigation of Potential Impacts to Paleontological Resources". The characterization shall include subsurface excavations within the proposed solar field to a depth equal to the maximum depth of panel post insertion. All excavations shall be logged and sampled by a qualified paleontologist under the direct supervision of the paleontological resource specialist (PRS). The number of excavations shall be statistically significant determined in accordance with current statistical procedures similar to those presented in *Information Technology, Learning, and Performance Journal, Vol. 19, No. 1, Spring 2001*. Following completion of the field work, the project owner shall document the findings and interpretations in a paleontological

characterization report. The paleontological characterization report shall contain:

1. Date(s) of the fieldwork and names of any personnel assisting with the fieldwork.

2. Brief description of project and expected impacts to paleontological resources.

3. A description of field methods used.

4. A summary of findings, including important discoveries.

5. A discussion of the significance of the findings/discoveries.

6. A description of potentially fossiliferous areas to allow for future assessment of sites, even if no fossils were located during the project monitoring.

7. A completed BLM locality form 8270-3 or equivalent for each new locality, using Universal Transverse Mercator (UTM) NAD 83 coordinates, and 1:24000 scale maps with new localities plotted using points or polygons as appropriate.

8. Locality forms, maps, and any other information containing specific fossil locations will be bound separately or assembled as a separate section to allow for preservation of confidential locality data.

9. List of specimen field numbers and field identifications of collected material, cross-referenced to the locality field number. This list may be submitted in electronic format, preferably in a spreadsheet format.

10. A summary of regional and local geology; this will reference earlier projects for relevant information.

11. A summary of regional and local paleontology; this will reference earlier projects for relevant information.

12. Potential impacts to paleontological resources resulting from the project.

13. Map of project area, indicating areas surveyed, known localities, and new discoveries.

14. Relevant photos, diagrams, tables to aid in explaining, clarifying, or understanding the findings.

If the CPM determines significant paleontological resources are statistically significant at the site the project owner will be required to implement one of the following:

A. Provide an assessment of how avoidance of the sensitive geologic units containing significant paleontological resources may be accomplished so impacts can be minimized. The CPM shall review and approve the assessment prior to implementation.

B. Where avoidance cannot be achieved in all or part of the solar field the Project Owner shall provide an assessment of alternative foundations design and construction methods that may be used in the areas where significant paleontological resources are identified. The CPM shall review and approve the assessment prior to implementation.

C. Where avoidance and alternative foundation design and construction cannot be accomplished the project owner shall conduct additional excavation and collection of paleontological resources for curation such that the collection adequately assesses the scientific significance of the site and preserves a cross-section of material that can be used for future analysis and the benefit of public appreciation.

If the results of the study show that there are no or limited significant paleontological resources in the solar field where pylons will be driven the CPM may find that monitoring and mitigation in accordance with Condition of Certification PAL-1 through PAL-8 are adequate to ensure no significant impacts.

Verification:

1) At least 90 days prior to the start of ground disturbance, the project owner shall submit the paleontological characterization plan to the CPM for review and approval.

2) At least 30 days prior to ground disturbance, the project owner shall initiate field work in the areas where ground disturbance will first be conducted. The field work shall proceed sequentially in areas scheduled for panel foundation installation and shall precede panel foundation installation by a period of not less than 7 days.

3) At least 30 days prior to ground disturbance, the project owner shall provide a panel foundation construction schedule to the CPM.

4) No more that 90 days after completion of panel foundation construction, the project owner shall provide the CPM a draft paleontological characterization report for review and comment.

5) The findings of the solar field paleontological characterization shall be incorporated into the PRR required in PAL -7, above.

Certification of Completion
Worker Environmental Awareness Program
Palen Solar Electric Generating System (09-AFC-7)

This is to certify these individuals have completed a mandatory California Energy Commission–approved Worker Environmental Awareness Program (WEAP). The WEAP includes pertinent information on cultural, paleontological, and biological resources for all personnel (that is, construction supervisors, crews, and plant operators) working on-site or at related facilities. By signing below, the participant indicates that he/she understands and shall abide by the guidelines set forth in the program materials. Include this completed form in the Monthly Compliance Report.

POWER PLANT EFFICIENCY

Testimony of Edward Brady

SUMMARY OF CONCLUSIONS

The Palen Solar Electric Generating System (PSEGS), if constructed and operated as proposed, would use solar energy to generate a minimum 98 percent of its annual electrical energy production. Fossil fuel, in the form of natural gas, would be used only to reduce startup time and to keep the temperature of the steam generation system above freezing temperatures. Compared to the project's expected overall production rate of approximately 1,412,300 megawatt-hours (MWh) per year, and compared to a typical fossil fuel-fired power plant of equal capacity, the amount of the annual power production from fossil fuel is insignificant at less than 2 percent (Palen 2012a, § 2.1-1).

The project would decrease dependence on fossil fuel, and would increase renewable energy generation. It would not create significant adverse effects on fossil fuel energy supplies or resources, would not require additional sources of energy supply, and would not consume fossil fuel energy in a wasteful or inefficient manner. No efficiency standards apply to this project. Staff therefore concludes that this project would present no significant adverse impacts on fossil fuel energy resources.

The modified PSEGS would occupy approximately 7.6 acres per megawatt (MW) of capacity, which approximates other similar solar power technologies.

INTRODUCTION

The proposed modified PSEGS would generate 500 MW (nominal net output) of electricity. PSEGS would be a solar thermal power plant built on an approximately 3,794-acre site in Riverside County, California. The project would use the solar thermal power tower technology to produce electrical power using steam turbine generators fed from solar steam generators. Fossil fuel, in the form of natural gas, would be used to reduce startup time and to keep the temperature of the steam generation system above freezing.

METHODOLOGY AND THRESHOLDS FOR DETERMINING ENVIRONMENTAL CONSEQUENCES

FOSSIL FUEL USE EFFICIENCY

One of the responsibilities of the Energy Commission is to make findings on whether the energy use by a power plant, including the proposed PSEGS, would result in significant adverse impacts on the environment, as defined in the California Environmental Quality Act. If the Energy Commission finds that the proposed modified project's energy consumption creates a significant adverse impact, it must further determine if there are feasible mitigation measures that could eliminate or minimize that impact, and then, require implementation of those mitigation measures.

In order to develop the Energy Commission's findings, this analysis will:

- examine whether the facility would likely present any adverse impacts upon energy resources; and if so,
- examine whether these adverse impacts are significant; and if so,
- examine if there are feasible mitigation measures or alternatives that could eliminate those adverse impacts or reduce them to a level of less-than-significance; and if so,
- recommend that the project implement those mitigation measures.

SOLAR LAND USE EFFICIENCY

Solar thermal power plants typically consume much less fossil fuel (usually in the form of natural gas) than other types of thermal power plants. Therefore, common measures of power plant efficiency such as those described above are less meaningful. So far as Energy Commission staff can determine, methods for determining the efficiency of a solar power plant have yet to be standardized; research has uncovered no meaningful attempt to quantify efficiency. The solar power industry appears to have begun discussing the issue, but a consensus has not emerged. In the absence of accepted standards, staff proposes the following approach.

Solar thermal power plants convert the sun's energy into electricity in three basic steps:

- Mirrors and/or collectors capture the sun's rays.
- This solar energy is converted into heat.
- This heat is converted into electricity, typically in a heat engine such as a steam turbine generator.

The effectiveness of each of these steps depends on the specific technology employed; the product of these three steps determines the power plant's overall solar efficiency. The greater the project's solar efficiency, the less land the plant must occupy to produce a given power output.

The most significant environmental impacts caused by solar power plants result from occupying large expanses of land. The extent of these impacts is likely in direct proportion to the number of acres affected. For this reason, staff evaluates the land use efficiency of proposed solar power plant projects. This efficiency is expressed in terms of power produced, or MW per acre, and in terms of energy produced, or annual MW-hours per acre. How efficiently a project uses land includes, but is not limited to, the site terrain and gradients, types of soils, the number of washes and waters of the US and state, and the technology. Staff calculates the relative efficiencies to verify that the project is consistent with similar technologies – not that one project is superior to another project. Specifically:

- For land use efficiency, the solar industry uses the ratio of acreage and nominal power output (acres/MW) and its reciprocal (MW/acre) interchangeably to compare land utilization of solar powered electrical generation systems.

- Energy-based solar land use efficiency is calculated by dividing the annual net electrical energy production in MW-hours per year by the total number of acres impacted by the power plant, which accounts for the fraction of energy production, morning start-up and nighttime freeze control utilizing non-renewable fuel sources such as natural gas and propane.
- Acreage is defined in the capacity and energy factors above as the area used directly as solar fields plus the common service area, but excluding access roads, transmission rights-of-way and utility corridors, and any mitigation areas.
- Where the method for maintaining start-up status is not otherwise identified, refer to **APPENDIX A** for a list of proxy combined cycle baseload generation facilities to calculate an equivalent start-up fuel factor and derive a "solar only" net annual energy generation.

See **Efficiency Table 1** below for a comparison of various solar and conventional electric power generation facilities in terms of land utilization, power generation efficiency and net energy generation efficiency.

PROPOSED MODIFIED PROJECT

The Final Decision describes the PSEGS as a solar thermal project using parabolic trough technology. Under the modified PSEGS, the troughs and associated heat transfer fluid (HTF) will be eliminated and PSEGS will be reconfigured to utilize BrightSource's solar tower technology consisting of two solar towers, associated power blocks, and heliostat fields. Power plant efficiency impacts from the modified project are expected to be similar to the approved project (see analysis below).

SETTING AND EXISTING CONDITIONS

The applicant proposes to build and operate PSEGS, a solar thermal power plant producing a total of 500 MW (nominal net output) and employing the power tower solar thermal technology. The project would consist of two units, each comprised of arrays of approximately 85,000 heliostat mirrors, solar steam generator heat exchangers, one steam turbine generator, and an air cooled condenser (Palen 2012a, § 2.2.1). Each 250 MW power tower would be surrounded by a circular array of heliostats with the closest radial array about 250 feet from the base of the 720-foot-tall tower and the farthest approximately 750 feet from the base of this tower. What would appear to be random spacing and partial rows would be designed to accommodate the topography of the site and minimize panel-to-panel shading as the sun runs a celestial chord across the hemispheric array (Palen 2012a, § 2.2.1.3).The project's power cycle would be based on a steam cycle (also known as the Rankine cycle). The solar receiver steam generator (SRSG) at the top of the 750-foot-tall tower structure would feed the steam turbine generators which would produce electric power.

Each unit of the project would utilize a natural gas-fired auxiliary boiler with 249 million Btu per hour (mmBtu/hr) thermal input to accelerate startup and have the solar system warm at first sunlight. A second nighttime restoration boiler with 10 mmBtu/hr thermal input would provide overnight freeze protection.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

PROJECT ENERGY REQUIREMENTS AND ENERGY USE EFFICIENCY

PSEGS would consume insignificant amounts of fossil fuel for power generation. It would consume fossil fuel only to reduce startup time and provide nighttime freeze protection.

The project would consume natural gas at a maximum annual rate of 742,000 mmBtu (Palen 2012a, Table 2.2-2). Compared to a typical fossil fuel-fired power plant of equal capacity, and compared to the relatively considerable resources of fossil fuel in California (see below in **ADVERSE EFFECTS ON ENERGY SUPPLIES AND RESOURCES**), this rate is not significant. Natural gas is comparable in efficiency to common fossil fuels,[1] with a heat rate that is 1.8 percent higher than propane and 9.2 percent higher than diesel fuel.

The applicant estimates a full load thermodynamic efficiency of 43.6 percent for the proposed modified project (Palen 2012a, Figure 2.2-3A). There are currently no legal or industry standards for measuring the efficiency of solar thermal power plants. Staff compares the steam cycle efficiency of PSEGS to the average efficiency of contemporary fossil fuel steam turbines currently available in the market. The efficiency figures for these turbines range from 35 to 45 percent. The project's thermal efficiency of 43.6 percent is comparable to this industry range. Coupled with the 2 percent restriction on the use of natural gas for energy generation (Palen 2012a, § 2.2.1, Table 2.2-1), the solar-driven thermal steam cycle efficiency provides a simple, work-proven method of electric power generation, eliminating the heat exchange losses of an intermediate HTF circuit.

Therefore, staff considers the impact of the project's fuel consumption on energy supplies and energy efficiency to be less than significant.

ADVERSE EFFECTS ON ENERGY SUPPLIES AND RESOURCES

The applicant has described its sources of natural gas for the project (PSEGS 2012a, § 2.3) The project has access to an abundance of natural gas through the 200 psig gas transmission line that runs along Interstate Highway 10 (I-10). Owned by Southern California Gas Company, this pipeline is connected to natural gas resources from the Rocky Mountains, Canada and the southwest. The gas transmission system, of which the I-10 pipeline is part, has the capability of carrying up to 258.33 million cubic feet per hour ($mmft^3/hr$) from production areas in the Permian Basin of west Texas and the San Juan Basin of southern Colorado. The maximum natural gas demand from the project would be 0.53 $mmft^3/hr$; approximately 0.2 percent of this capacity. Therefore, it would be highly unlikely that the project would create a substantial increase in fossil fuel demand.

[1] Source: **APPENDIX A**, Biomass Energy Databook – 2011 – http://cta.orni.gof/bedb. LHV rates for natural gas (20,267 Btu/lbm/983 Btuh/CF), propane (19,904 Btu/lbm) fuel oil/diesel (18,397 Btu/lbm).

ADDITIONAL ENERGY SUPPLY REQUIREMENTS

There appears to be no real likelihood that PSEGS would require the development of additional energy supply capacity (see above in **ADVERSE EFFECTS ON ENERGY SUPPLIES AND RESOURCES**).

COMPLIANCE WITH ENERGY STANDARDS

No standards apply to the efficiency of PSEGS or other non-cogeneration projects.

ALTERNATIVES TO REDUCE WASTEFUL, INEFFICIENT, AND UNNECESSARY ENERGY CONSUMPTION

Staff typically evaluates the project alternatives to determine if alternatives exist that could reduce the project's fuel use. The evaluation of alternatives to the project (that could reduce wasteful, inefficient, or unnecessary energy consumption) requires the examination of the project's energy consumption.

Efficiency of Alternatives to the Project

Please see the project alternatives discussed below.

Alternative Generating Technologies

Alternative generating technologies for PSEGS are considered in PSEGS 2012a Petition to Amend. For purposes of this analysis, natural gas, oil, coal, nuclear, geothermal, biomass, hydroelectric, wind and solar photovoltaic technologies were all considered. Because this project would consume insignificant amounts of fossil fuel for power production, staff believes that the proposed modified project would not constitute a significant adverse impact on fossil fuel energy resources compared to feasible alternatives.

The solar insolation radiating on the earth's surface can be regarded as an energy resource. Since this energy is relatively inexhaustible, its consumption does not illicit the concerns endemic to fossil fuel consumption. What is of concern, however, is the extent of land area required to convert this solar energy into electricity. Setting aside hundreds or thousands of acres of land for solar power generation removes it from alternative uses.

As discussed above, Energy Commission staff is unaware of any accepted standards for evaluating the efficiency of a solar power plant such as PSEGS. As a substitute, staff tabulates the land use efficiency of the project (described above) and compares it to similar measures for other solar power plant projects that have passed through, or are passing through the Energy Commission's siting process; see **Efficiency Table 1**, below. It has not been determined how great a difference in land use would constitute a significant difference. The solar land use efficiency for a typical natural gas-fired combined cycle power plant is shown only for comparison.

A solar power project that occupies more land than another project holds the potential to produce more environmental impacts. PSEGS would produce power at the rate of 500 MW net, and would generate energy at the rate of 1,412,300 MW-hours net per year, while occupying 3,794 acres (Palen 2012a, Figures 1 and 2.1-4, Table 2.2-1).

Staff calculates the comparative land use and energy-based efficiencies below:

Land Use Efficiency: 500 MW ÷ 3,794 acres = **0.13 MW/acre**; or
3,794 acres ÷ 500 MW = **7.6 acres/MW**

Energy-Based Land Use Efficiency: 1,412,300 MWh/hr ÷ 3,794 acres = **372 MWh/year**

Alternatives to Reduce Solar Land Use Impacts

Building and operating a natural gas-fired combined cycle power plant would yield much greater land use efficiency than any solar power plant; see **Efficiency Table 1**. However, this would not achieve the basic project objective, to generate electricity from the renewable energy of the sun.

As seen in **Efficiency Table 1**, PSEGS, employing BrightSource's power tower technology, is slightly less efficient in the use of land than Hidden Hills SEGS which uses BrightSource's power tower technology as well, but more efficient than Ivanpah SEGS which also employs BrightSource's power tower technology. PSEGS is slightly more land-use-efficient than the original Calico Solar project, a Stirling Engine solar project. PSEGS's land use efficiency is in the midrange of the efficiency figures listed in **Efficiency Table 1**. Also, compared to the other projects listed in this table, PSEGS would burn more fossil fuel per acre of land and per MW; see the last two columns.

The modified PSEGS would occupy approximately 7.6 acres of land per MW of power generation, or 0.13 MW/acre. The approved PSPP would occupy approximately 2,970 acres of land for the solar field, common areas, and power blocks (Solar Millennium 2009a, AFC §§ 2.0, 2.1, 2.2.1), plus approximately 926 acres of land set aside for grading and drainage which would be required for the PSPP project (Palen 2013j, Supplement No. 3, p.1-1). Based on the total acreage (2,970+926=3,896) and the nominal gross output of 500 MW, the approved PSPP would occupy approximately 7.8 acres of land per MW of power generation, or 0.13 MW/acre. As seen here, from a land use efficiency standpoint, the modified project would be similar to the approved project.

Efficiency Table 1
Solar Land Use Efficiency[1]

Projects	Generating Capacity (MW net)	Annual Energy (mmBtu) net	Annual Fuel Consumption (mmBtu, lower heating value [LHV[1]])	Footprint (Acres)	Land Use Efficiency (MW/acre)	Land Use Efficiency (Energy–Based) (MWh/acre-year)	
						Total	Solar Only[2]
Palen Solar (09-AFC-7C)	**500**	**1,401,900**	**742,000**	**3,794**	**0.13**	**372**	**342**
Beacon Solar (08-AFC-2)	250	600,000	36,000	1,240	0.20	484	480
Hidden Hills SEGS (11-AFC-04)	500	1,412,000	94,907	3,097	0.16	463	458
Ivanpah SEGS (07-AFC-5)	400	960,000	432,432	3,744	0.11	256	238
Imperial Valley Solar (08-AFC-5)	750	1,620,000	0	6,500	0.12	249	249
Calico Solar (08-AFC-13)	850	1,840,000	0	8,200	0.11	224	224
Avenal Energy (08-AFC-1)[3]	600	3,023,000	24,792,786	25	24.0	120, 936	N/A

Notes:
1. LHV is Low Heating Value, or a measurement of the energy content of a fuel correcting for post-combustion water vapor.
2. Net energy output is reduced by natural gas-fired combined cycle proxy energy output; see **Efficiency Appendix A**.
3. Example natural gas-fired combined cycle plant.

Alternative Heat Rejection System

The applicant proposes to employ a dry cooling system (air-cooled condensers) as the means for rejecting power cycle heat from the steam turbines (Palen 2012a, § 2.2.1.4). An alternative heat rejection system would utilize evaporative cooling towers.

The local climate in the project area is characterized by high temperatures and low relative humidity (low wet-bulb temperature). In low temperatures and high relative humidity (low dry-bulb temperature), the air-cooled condenser performs relatively efficiently compared to the evaporative tower. However, at the project area (low wet-bulb temperature and high dry-bulb temperature) the air-cooled condenser performance is relatively poor compared to that of an evaporative cooling tower. Furthermore, the performance of the heat rejection system affects the performance of the steam turbine, which affects turbine efficiency and the net power output. However, an air cooled condensers uses a relatively small amount of water than an evaporative cooling tower. Although power production is marginally reduced by the use of an air cooled condenser, the benefit of reducing water consumption countervails the impact on power production at a desert site. Even though evaporative cooling could offer greater power production, resulting in higher efficiency, staff believes the applicant's selection of dry cooling is a reasonable tradeoff because it would prevent potentially significant environmental impacts that could result from consumption of the large quantities of water required by wet cooling.

CUMULATIVE IMPACT ANALYSIS

There are no nearby power plant projects or other projects consuming large amounts of fossil fuel that hold the potential for cumulative energy consumption impacts when aggregated with the project. This project controls its own use of natural gas by specifying 2 percent annual energy production as a limit (Palen 2012a, § 2.2.1). Where solar tower resources share regional locales, their unimpeded access to solar radiation does not place them in competition with other solar (or non-solar) facilities within their proximate.

As a renewable energy source, solar energy would have an influence on the daily power demand profile and technologies such as multi-stage generation that would have to emerge to enhance the efficient utilization of solar power. In the long term, these trends will serve to improve the power generation mix and provide the electricity grid system with accessible methods of managing and controlling generation facilities within their purview.

More immediately, staff believes that the construction and operation of the project would not create indirect impacts (in the form of additional fuel consumption) that would not have otherwise occurred without this project. Because the proposed modified project would consume significantly less fossil fuel than a typical fossil fuel-fired power plant, it should compete favorably in the California power market and replace older fossil fuel burning power plants. The project would therefore cause a positive impact on the cumulative amount of fossil fuel consumed for power generation.

COMPLIANCE WITH LORS

No federal, state, or local/county laws, ordinances, regulations, and standards (LORS) apply to the efficiency of this project.

NOTEWORTHY PUBLIC BENEFITS

PSEGS would employ an advanced solar thermal technology. Solar energy is renewable and unlimited. The project would have a less than significant adverse impact on nonrenewable energy resources. Consequently, the project would help in reducing California's dependence on fossil fuel-fired power plants.

RESPONSE TO COMMENTS

Staff received no comments relating to Power Plant Efficiency.

CONCLUSIONS

LAND USE

The modified PSEGS project would occupy approximately 7.6 acres per MW of power output, or 0.13 MW/acre; in the midrange of efficiency figures that include several other solar thermal power plant projects (see **Efficiency Table 1**).

FOSSIL FUEL ENERGY USE

The modified PSEGS project would use solar energy to generate most of its capacity, consuming insignificant amounts of fossil fuel for power production. The project would decrease reliance on fossil fuel, and would increase reliance on renewable energy resources. It would not create significant adverse effects on energy supplies or resources, would not require additional sources of energy supply, and would not consume energy in a wasteful or inefficient manner. No energy standards apply to this project.

Staff therefore concludes that this project would present no significant adverse impacts on energy resources. No cumulative impacts on energy resources are likely. Facility closure would not likely present significant impacts on electric system efficiency.

PROPOSED CONDITIONS OF CERTIFICATION/MITIGATION MEASURES

No conditions of certification are proposed.

EFFICIENCY APPENDIX A
SOLAR POWER PLANT EFFICIENCY CALCULATION
GAS-FIRED PROXY

In calculating the efficiency of a solar power plant, it is desired to subtract the effect of natural gas burned for morning startup, cloudy weather augmentation and freeze protection. As an alternative, staff would use an average efficiency based on several recent baseload combined cycle power plant projects in the Energy Commission siting process. Baseload combined cycles were chosen because their intended dispatch most nearly mirrors the intended dispatch of solar plants, that is, operate at full load in a position high on the dispatch authority's loading order.

Examples of base load combined cycle "proxy" systems include:

Colusa Generating Station (06-AFC-9)

- Nominal 660 MW 2-on-1 Combined Cycle with GE Frame 7FA CGTs
- Air cooled condenser, evaporative inlet air cooling
- Efficiency with duct burners on: 666.3 MW @ 52.5% LHV
- Efficiency with duct burners off: 519.4 MW @ 55.3% LHV
- Efficiency (average of these two): **53.9% LHV**

San Gabriel Generating Station (07-AFC-2)

- Nominal 696 MW 2-on-1 Combined Cycle with Siemens 5000F CGTs
- Air cooled condenser, evaporative inlet air cooling
- Efficiency with duct burners on: 695.8 MW @ 52.1% LHV
- Efficiency with duct burners off: 556.9 MW @ 55.1% LHV
- Efficiency (average of these two): **53.6% LHV**

Avenal Energy (08-AFC-1)

- Nominal 600 MW 2-on-1 Combined Cycle with GE Frame 7FA CGTs
- Air cooled condenser, inlet air chillers
- Efficiency with duct burners on: 600.0 MW @ 50.5% LHV
- Efficiency with duct burners off: 506.5 MW @ 53.4% LHV
- Efficiency (average of these two): **52.0% LHV**

Average of these four power plants: **53.2% LHV**

POWER PLANT RELIABILITY

Testimony of Edward Brady

SUMMARY OF CONCLUSIONS

Based on a review of the Petition to Amend, staff concludes that, similar to the approved project, the modified project, referred to as the Palen Solar Electric Generating System (PSEGS) would be built and would operate in a manner consistent with industry norms for reliable operation. The project owner predicts an equivalent availability factor of between 92 and 98 percent for the modified project, which staff believes is achievable and comparable to the original unamended system proposed for Palen. (The equivalent availability factor of a power plant is the percentage of time it is available to generate power, accounting for both planned and unplanned outages.) No conditions of certification are proposed.

INTRODUCTION

In this analysis, California Energy Commission (Energy Commission) staff addresses the reliability issues of PSEGS to determine if the power plant is likely to be built in accordance with typical industry norms for reliable power generation. Staff uses this norm as a benchmark because it ensures that the resulting project would not be likely to degrade the overall reliability of the electric system it serves (see the “Setting” subsection, below).

The scope of this power plant reliability analysis covers:

- equipment availability;
- plant maintainability;
- fuel and water availability; and
- power plant reliability in relation to natural hazards.

Staff examined the project design criteria to determine if the project is likely to be built in accordance with typical industry norms for reliable power generation. While the project owner has predicted an availability factor of between 92 to 98 percent for PSEGS (Palen 2012a, § 3.1.4.1), staff has used industry norms as the benchmark, rather than the project owner’s projection, to evaluate the project’s reliability.

METHODOLOGY AND THRESHOLDS FOR DETERMINING ENVIRONMENTAL CONSEQUENCES

METHOD FOR DETERMINING RELIABILITY

The Energy Commission must make findings as to how a project is designed, sited, and operated in order to ensure its safe and reliable operation (Title 20, CCR § 1752[c]). Staff takes the approach that a project is acceptable if it does not degrade the reliability of the utility system to which it is connected. This is likely the case if a project is at least as reliable as other power plants on that system.

The equivalent availability factor is the percentage of time the power plant is available to generate power, accounting for both planned (maintenance) and unplanned outages (extreme inclement weather). For a solar power plant, the availability factor is a percentage of only daytime hours because the technology does not produce electricity at night. Measures of power plant reliability are based upon both the plant's actual ability to generate power when it is considered to be available and upon starting failures and unplanned (or forced) outages. For practical purposes, reliability can be considered a combination of these two industry measures, making a reliable power plant one that is available when called upon to operate. Throughout its intended 30-year life, PSEGS is expected to operate reliably (Palen 2012a, § 3.1.4). Power plant systems must be able to operate for extended periods without shutting down for maintenance or repairs. Achieving this reliability requires adequate levels of equipment availability, plant maintainability with scheduled maintenance outages, fuel and water availability, and resistance to natural hazards. Staff examines these factors for the project and compares them to industry norms. If the factors compare favorably for this project, staff may then conclude that PSEGS would be as reliable as other power plants on the electric system and would not degrade system reliability.

PROPOSED MODIFIED PROJECT

The Final Decision describes the approved project as a solar thermal project using parabolic trough technology. Under the modified project, the troughs and associated HTF will be eliminated and the PSEGS would be reconfigured to utilize BrightSource's solar tower technology consisting of two solar towers and associated power blocks and heliostat fields.

SETTING AND EXISTING CONDITIONS

In the restructured competitive electric power industry, the responsibility for maintaining system reliability falls largely to the state's control area operators, such as the California Independent System Operator (California ISO), that purchase, dispatch, and sell electric power throughout the state. Determining how the California ISO and other control area operators would ensure system reliability has been an ongoing effort. Protocols that allow sufficient reliability to be maintained under the competitive market system have been developed and put in place. "Must-run" power purchase agreements and "participating generator" agreements are two mechanisms that have been employed to ensure an adequate supply of reliable power.

The California ISO's mechanisms to ensure adequate power plant reliability apparently were devised under the assumption that the individual power plants that compete to sell power into the system will each exhibit a level of reliability similar to that of power plants of past decades. However, there has been valid cause to believe that, under free market competition, financial pressures on power plant owners to minimize capital outlays and maintenance expenditures may act to reduce the reliability of many power plants, both existing and newly constructed (McGraw-Hill 1994).[1] It is possible that, if significant numbers of power plants were to exhibit individual reliability sufficiently lower

[1] pg.11, Sanden, Gary et al., "Operational Experience in Competitive Electric Generation, McGraw-Hill's Independent Audit of US Non-Utility Powerplants", McGraw Hill Inc. (New York, 1994).

than this historical level, the assumptions used by California ISO to ensure system reliability would prove invalid, with potentially disappointing results. Accordingly, staff has recommended that power plant owners continue to build and operate their projects to the level of reliability to which all in the industry are accustomed.

As part of its plan to provide needed reliability, the project owner proposes to operate the 500-megawatt (MW) (net power output) PSEGS, a solar thermal power plant facility employing advanced solar power technology. This project, using renewable solar energy, would provide dependable power to the grid, generally during the hours of peak power consumption by the interconnecting utility(s). This project would help serve the need for renewable energy in California.

The project owner has indicated it expects the modified project to achieve an availability factor of between 92 and 98 percent (Palen 2012a, § 2.12). The project is anticipated to operate at an annual capacity factor of approximately 32 percent.[2]

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

EQUIPMENT AVAILABILITY

Equipment availability would be ensured by adoption of appropriate quality assurance/ quality control (QA/QC) programs during the design, procurement, construction, and operation of the plant and by providing for adequate maintenance and repair of the equipment and systems discussed below.

Quality Control Program

The project owner describes a QA/QC program (Palen 2012a, § 3.1.4.5) that is typical of the power industry. Equipment would be purchased from qualified suppliers based on technical and commercial evaluations. Suppliers’ personnel, production capability, past performance, QA programs, and quality history would be evaluated. The project owner would perform receipt inspections, test components, and administer independent testing contracts. Staff expects that implementation of this program would result in typical reliability of design and construction. To ensure this implementation, staff has proposed appropriate conditions of certification in the section of this document entitled **FACILITY DESIGN**.

PLANT MAINTAINABILITY

Equipment Redundancy

The PESGS project would be able to operate only when the sun is shining. Maintenance or repairs could be done when the plant is shut down at night. This would help to enhance the project’s reliability. The fact that the project would consist of two separate units operating separately provides inherent reliability. A single equipment failure cannot disable more than one unit, thus allowing the plant to continue to generate (at reduced output). The nature of solar thermal generating technology also provides inherent redundancy; the singular nature of the heliostats would allow for

[2] Derived from PSEGS Petition, Table 2.2.1: 1,412,300 MWh (500 MW x 8760 hours) = 0.322/32.2%.

reduced output generation if one heliostat, or even hundreds of heliostats, was to require service or repair. This redundancy would allow service or repair to be done during sunny days when the plant is in operation, if required. Major plant systems are designed with adequate redundancy to ensure their continued operation if equipment fails (Palen 2012a, § 3.1.4.2, Table 3.1-1). Approximately 85,000 heliostats per unit would provide an excess of reflective surface area to accommodate the queuing of heliostats through a standby position before focusing them on the solar receiver steam generator (SRSG) at the top of the power tower (Palen 2012a, §§ 2.2.1.2, 2.2.1.3). The requirement for providing excess reflective surface is based on the information provided by BrightSource for Hidden Hills Solar Electric Generating Systems and Rio Mesa Solar Electric Generating System projects, which have unit areas that provide the identical nominal capacity of 250 MW as PSEGS. In each case, the heliostats would be located to accommodate 1) specific topographical conditions for each unit site; 2) efficiency factors which account for panel shadowing, tower blockage, mirror spillage, transmittance characteristics of the mirrors and SRSG, and the characteristic cosine effect; 3) standby factor for bringing heliostats on- and off-line; and 4) panel reserves for handling offline maintenance and repair.

Maintenance Program

Equipment manufacturers provide maintenance recommendations for their products, and the project owner would most likely base the project's maintenance program on those recommendations. Such a program would encompass both preventive and predictive maintenance techniques. Maintenance outages would probably be planned for periods of low electricity demand. Staff expects that the project would be adequately maintained to ensure an acceptable level of reliability.

FUEL AND WATER AVAILABILITY

The long-term availability of fuel and of water for cooling or process use is necessary to ensure the reliability of any power plant. The need for reliable sources of fuel and water is obvious; lacking long-term availability of either source, the service life of the plant could be curtailed, threatening both the power supply and the economic viability of the plant.

Fuel Availability

The project owner has described its sources of natural gas for the modified project (Palen 2012a, § 2.3). The project has access to an abundance of natural gas through the 200 psig gas transmission line that runs along Interstate Highway 10. Owned by SoCal Gas, this pipeline is connected to natural gas resources spanning the Rocky Mountains, Canada and the southwest. The gas transmission system, of which the I-10 pipeline is a part, is an existing infrastructure that has the capability of carrying up to 6.2 billion cubic feet per day from production areas in the Permian Basin of west Texas and the San Juan Basin of southern Colorado.[3] The maximum possible natural gas demand from the project is 0.53 million cubic feet per hour, constituting about 2 percent of this

[3] U.S Energy Information Administration, "Natural Gas Pipelines in the Western Region, http://www.eia.gov/pub/oil_gas/analysis_publications/ngpipeline/western.html.

capacity. Therefore, it would be highly unlikely that the project would create a substantial increase in fossil fuel demand. Staff believes that there will be adequate fuel supply to meet the project's needs.

Water Supply Reliability

PSEGS has proposed to use well water for domestic and industrial water needs, including steam cycle makeup, mirror washing, service water and fire protection water. The project would be dry cooled, so no water would be required for power plant cooling. The quantities of water to be consumed by the project are relatively small compared to the capacity of the resource available, and it seems feasible to physically draw out the water for delivery to the project site. Thus, this source of water supply seems adequate. Therefore, staff concludes that this source of water supply is a reliable source of water for the project (see the **SOIL AND WATER RESOURCES** section of this document for a further discussion of water supply).

POWER PLANT RELIABILITY IN RELATION TO NATURAL HAZARDS

Natural forces can threaten the reliable operation of a power plant. Tsunamis (tidal waves) and seiches (waves in inland bodies of water) are not likely to present hazards for this project, but seismic shaking (earthquakes), flooding and high winds could present credible threats to the project's reliable operation (Solar Millennium 2009a, AFC §§ 2.5.6, 5.5.2, 5.17.2.9, Palen 2012a, § 3.1.3.4).

Seismic Shaking

No active faults are present within the project boundaries or within a 2.5 mile radius of the site (Palen 2012a, § 3.1.3.4); see the "Faulting and Seismicity" portion of the **GEOLOGY AND PALEONTOLOGY** section of this document. The project will be designed and constructed to the latest applicable LORS (Solar Millennium 2009a, AFC Appendix C). Compliance with current seismic design LORS represents an upgrading of performance during seismic shaking compared to older facilities since these LORS have been continually upgraded. Because it would be built to the latest seismic design LORS, this project would likely perform at least as well as, and perhaps better than, existing plants in the electric power system. Staff has proposed conditions of certification to ensure this; see the section of this document entitled **FACILITY DESIGN**. In light of the general historical performance of California power plants and the electrical system in seismic events, staff has no special concerns with the power plant's functional reliability during earthquakes.

Flooding

Portions of the site lie within a 100-year or 500-year flood plain (Solar Millennium 2009a, AFC § 5.17.1.3). Project features would be designed and built to provide adequate levels of flood resistance. Staff believes there are no special concerns with power plant functional reliability due to flooding. For further discussion, see **WATER RESOURCES** and **GEOLOGY AND PALEONTOLOGY**.

High Winds

High winds are common in the region of the site, which could potentially cause damage to the solar mirrors. Project features would be built to withstand wind loading; however, mirror arrays would have to be stowed during high winds to protect the mirrors. Design would be in accordance with applicable LORS, including the 2010 California Building Code (**Facility Design**). Staff believes there are no special concerns with power plant functional reliability due to wind.

COMPARISON WITH EXISTING FACILITIES

The North American Electric Reliability Corporation (NERC) maintains industry statistics for availability factors (as well as other related reliability data). The NERC regularly polls North American utility companies on their project reliability through its Generating Availability Data System (GADS) and periodically summarizes and publishes those statistics on the Internet at <http://www.nerc.com>. Energy Commission staff typically compares the project owner's claims for reliability to the statistical reliability of similar power plants. Because solar technology is relatively new and the technologies employed so varied, no NERC statistics are available for solar power plants. Staff's typical side-by-side comparison with other existing facilities thus does not apply. The project's power cycle is based on steam cycle, but the NERC data can be used as a benchmark.

Because natural gas is the primary type of fossil fuel used in California, staff finds it reasonable to compare the project's availability factor to the average availability factor of natural gas-fired fossil fuel units. Also, because the project's total net power output would be 500 MW, staff uses the NERC statistics for 400–599 MW units. The NERC reported an equivalent availability factor of 81.4 percent as the generating unit average during the years 2007 through 2011 for natural gas units of 400–599 MW (NERC 2012). The availability factor, which does not account for unplanned outages, comes in at 82.8 percent in the same period sample.

The PSEGS project would use triple-pressure (high, intermediate and low) condensing steam turbine technology. Steam turbines incorporating this technology have been on the market for many years and are expected to exhibit typically high availability. Also, because solar-generated steam is cleaner than combusted fossil fuel (i.e., natural gas), the PSEGS steam cycle units would likely require less frequent maintenance than units that burn fossil fuel, when subject to the same operating conditions. Therefore, the project owner's expectation of an annual availability factor of 92 to 98 percent (Palen 2012a, §§ 2.12, 3.1.4.1) appears reasonable when compared with the NERC figures throughout North America. In fact, these machines can be expected to outperform the fleet of various turbines (mostly older and smaller) that make up NERC statistics.

A concentrated solar power plant (CSP) is limited to daytime operation when the sun is shining. From a maintenance standpoint, scheduled short-term repairs can be made on a daily basis because of the diurnal nature of the solar energy supply. This feature would factor planned outages out of the availability calculations, leaving only unplanned outages as the singular event within the solar production day. The NERC data presented above reflects the downward trend of availability caused by the aging of the database sample used. Comparing the NERC data to a new facility does not fully reflect the benefits of current steam system technology to the determination of plant availability.

Counterpoint to high end availability would be operating conditions unique to CSP operation: 1) accommodation of planned maintenance that would necessarily extend longer than a nighttime period cycle; 2) the daily start-up cycle that would thermally stress the steam generation cycle system components more than continuous baseline operation; and 3) the interruption of power generation due to unforeseeable natural events such as cloud cover, wind storms and ground fog.

Rather than attempt derivation, staff looked at several existing CSPs with similar steam generation systems in duty and size: The Luz/NextEra Solar Electric Generating Systems SEGS III through IX.[4] Developed by Luz in the late 1990's and currently operated by NextEra, SEGS is located near Kramer Junction and Hinkley, California on the same desert plateau as PSEGS. The 2012 annual report for the SEGS project included availability factors which ranged from 86 percent to 92 percent.[5] Since these availability values are derived from real-time operation, the percentages already reflect the effects of extended planned maintenance, daily duty cycling and natural weather occurrences. By factoring out the intermediate HTF circuit and taking advantage of lessons learned from 10-15 years of CSP commercial experience, the project owner's 6 percent jump in availability range for PSEGS, i.e., 86-92 percent to 92-98 percent would not be unreasonable.

PROJECT-RELATED FUTURE ACTIONS

The Southern California Edison (SCE) Red Bluff Substation is expected to be operational in December, 2013. Staff concludes that there won't be any overlap of construction phase of SCE Red Bluff Substation and the PSEGS. The Red Bluff Substation would not impact the reliability of any power plant, including the proposed PSEGS, and therefore, no analysis is required.

NOTEWORTHY PUBLIC BENEFITS

This project, if successful, would help serve the need for renewable energy in California.

RESPONSE TO COMMENTS

Staff received no comments relating to Power Plant Reliability.

[4] SEGS III thru VII: Production Data in Compliance Report transmitted from Robert Fimbres/NextEra to Dale Rundquist/CEC dated 2/26/13. SEGS VIII and IX: Annual Compliance Report, SEGS VII & IX. Submitted to CEC, prepared by NextEra Energy Operation Services, LLC to Luz Solar Partners VIII & IX, Harper Lake, California.

[5] Discounting the January data, the plant's availability range and average would be 86-92 percent and 89 percent respectively. (This range is actually 81-92 percent, but the 81 percent low end value of this range includes a mid-winter January shutdown of all seven solar plants to install a design retrofit on the parabolic collector portion of the system and not related to the steam generation cycle.)

CONCLUSIONS

The project owner predicts an equivalent availability factor of between 92 and 98 percent, which staff believes is achievable and consistent with its own analyses. Based on a review of the proposal, staff concludes that the modified PSEGS would be built and would operate in a manner consistent with industry norms for reliable operation. No conditions of certification are proposed.

PROPOSED CONDITIONS OF CERTIFICATION

No Conditions of Certification are proposed.

TRANSMISSION SYSTEM ENGINEERING

Testimony of Laiping Ng and Mark Hesters

SUMMARY OF CONCLUSIONS

The proposed Palen Solar Electric Generating System (PSEGS) project has no substantial changes to Transmission System Engineering (TSE) compared to the original licensed Palen Solar Power Project (PSPP). Except for the change in generation technology, the generation output and the interconnection facilities remain unchanged. No new conditions or changes to conditions of certification are required.

The proposed interconnection facilities including the PSEGS 230 kV project switchyard, the 230 kV overhead generator tie-line, and its termination at the new Southern California Edison (SCE) Red Bluff substation, are acceptable and would comply with applicable laws, ordinances, regulations and standards (LORS).

The California Independent System Operator's (California ISO) approved PSEGS's conversion to solar tower from the original PSPP parabolic trough field technology. The California ISO's Transition Cluster Phase I and Phase II Interconnection Study Reports for the PSPP are applicable to the PSEGS.

The California ISO Transition Cluster Phase II Study Report – Group Report in SCE's Eastern Bulk System (Phase II Group Study) indicates the reliable interconnection and delivery of projects in the Eastern bulk system, which includes the PSEGS, would require the following upgrades to the existing or planned SCE transmission system:

- Replacement or upgrade of many circuit breakers at substations in the SCE system. Circuit breaker replacement generally occurs within the fence line of existing substation facilities.
- The use of new or expanded Special Protection Systems (SPS). These are essentially operating procedures that reduce the output of generators under specific conditions in order to avoid overloading transmission equipment.
- Reconductor of the drops of the Mira Loma–Vista 220 kV transmission line at the Vista substation. The "drops" are the portion of the line that comes into the substation.

The West of Devers upgrades, including reconductoring and relocation of four 220 kV transmission lines west of the Devers substation, have been identified in SCE transmission plans for several years starting in 2007 as needed to reliably serve future loads in the SCE service area and would therefore be needed to maintain system reliability even if the Eastern Bulk System generators were not constructed. Also, based on the SCE Devers-Palo Verde #2 Project upgrade timeline, the construction of the Red Bluff substation and looping the 2nd Colorado River–Devers 500 kV transmission line into the proposed Red Bluff substation is expected to be operational by the 3rd quarter of 2013.

INTRODUCTION

STAFF ANALYSIS

The Transmission System Engineering (TSE) analysis examines whether or not the facilities associated with the proposed interconnection conform to all applicable LORS required for safe and reliable electric power transmission. Staff's analysis evaluates the power plant switchyard, outlet line, termination facilities, and downstream facilities identified by the applicant. Additionally, under the California Environmental Quality Act (CEQA), the Energy Commission must conduct an environmental review of the "whole of the action," which may include facilities not licensed by the Energy Commission (California Code of Regulations, title 14, §15378). Therefore, the Energy Commission must identify the system impacts and necessary new or modified downstream transmission facilities (beyond the first point of the proposed interconnection) that are required for interconnection.

Energy Commission staff analyzes studies performed by the interconnecting authority, in this case the California ISO, to determine the impacts on the transmission grid from the proposed generator interconnection. Staff's analysis also identifies new or modified facilities downstream of the first point of interconnection that may be required as mitigation measures. The proposed project would connect to the SCE transmission network and requires analysis by SCE and approval of the California ISO.

CHANGING GENERATION TECHNOLOGY

On December 6, 2012, the Applicant filed a Modification Request to the California ISO for the change of the generation technology from parabolic trough field to solar tower. A response letter dated April 22, 2013, was sent to Chifong Thomas, Senior Director of the Transmission and Strategy for Brightsoruce Energy, Inc. from the California ISO. The California ISO letter stated that: "the ISO has not found a material impact on this change in generation technology; therefore, the conversion to solar tower is approved. Southern California Edison ("SCE") concurs with this analysis and the ISO will work with SCE and Brightsource to incorporate these modifications for the Project in an amendment to the LGIA".

As the change in generation technology has no material impact, the total generation output remains 500 MW, and the PSEGS interconnection would still be to the Red Bluff substation, the existing California ISO Phase I and Phase II Interconnection Studies are applicable to the new plant generation technology and configuration.

SOUTHERN CALIFORNIA EDISON'S ROLE

SCE is responsible for ensuring electric system reliability on its transmission system with the addition of the proposed transmission modifications, and determines both the standards necessary to ensure reliability and whether the proposed transmission modifications conform to existing standards. The California ISO will provide analysis in its Phase I and Phase II Interconnection Studies, and its approval for the facilities and changes required in its system for addition of the proposed transmission modifications.

California ISO'S Role

The California ISO is responsible for dispatching generating units in California, ensuring electric system reliability for all participating transmission owners and for developing the standards and procedures necessary to maintain system reliability. The California ISO will also determine the reliability impacts of the proposed transmission modifications on the SCE transmission system in accordance with all applicable reliability criteria. According to the California ISO Tariff, it will determine the need for transmission additions or upgrades downstream from the interconnection point to ensure reliability of the transmission grid. The California ISO performed the Phase I and Phase II Interconnection Studies and provided its analysis, conclusions, and recommendations. The Phase II Interconnection Study includes the California ISO conclusions and recommendations. If necessary, the California ISO will provide written and verbal testimony on its findings at the Energy Commission hearings.

LAWS, ORDINANCES, REGULATIONS, AND STANDARDS

- California Public Utilities Commission (CPUC) General Order 95 (GO-95), "Rules for Overhead Electric Line Construction", formulates uniform requirements for construction of overhead lines. Compliance with this order ensures adequate service and safety to persons engaged in the construction, maintenance and operation or use of overhead electric lines and to the public in general.
- California Public Utilities Commission (CPUC) General Order 128 (GO-128), "Rules for Construction of Underground Electric Supply and Communications Systems", formulates uniform requirements and minimum standards to be used for underground supply systems to ensure adequate service and safety to persons engaged in the construction, maintenance and operation or use of underground electric lines and to the public in general.
- The National Electric Safety Code, 2012 provides electrical, mechanical, civil and structural requirements for overhead electric line construction and operation.
- NERC/WECC Planning Standards: The Western Electricity Coordinating Council (WECC) Planning Standards are merged with the North American Electric Reliability Council (NERC) Planning Standards and provide the system performance standards used in assessing the reliability of the interconnected system. These standards require the continuity of service to loads as the first priority and preservation of interconnected operation as a secondary priority. Certain aspects of the NERC/WECC standards are either more stringent or more specific than the NERC standards alone. These standards provide planning for electric systems so as to withstand the more probable forced and maintenance outage system contingencies at projected customer demand and anticipated electricity transfer levels, while continuing to operate reliably within equipment and electric system thermal, voltage and stability limits. These standards include the reliability criteria for system adequacy and security, system modeling data requirements, system protection and control, and system restoration. Analysis of the WECC system is based to a large degree on NERC Standards TPL-001 through TPL-004 of the standards and "Table I. Transmission System Standards _ Normal and Emergency Conditions" and WECC Disturbance-Performance Table" and on Section I.D, "NERC and WECC Standards

for Voltage Support and Reactive Power". These standards require that the results of power flow and stability simulations verify defined performance levels. Performance levels are defined by specifying the allowable variations in thermal loading, voltage and frequency, and loss of load that may occur on systems during various disturbances. Performance levels range from no significant adverse effects inside and outside a system area during a minor disturbance (loss of load or a single transmission element out of service) to a level that seeks to prevent system cascading and the subsequent blackout of islanded areas during a major disturbance (such as loss of multiple 500 kV lines along a common right of way, and/or multiple generators). While controlled loss of generation or load or system separation is permitted in certain circumstances, their uncontrolled loss is not permitted (WECC Ongoing).

- North American Reliability Council (NERC) Reliability Standards for the Bulk Electric Systems of North America provide national policies, standards, principles and guidelines to assure the adequacy and security of the electric transmission system. The NERC Reliability Standards provide for system performance levels under normal and contingency conditions. With regard to power flow and stability simulations, while these Reliability Standards are similar to NERC/WECC Standards, certain aspects of the NERC/WECC Standards are either more stringent or more specific than the NERC Standards for Transmission System Contingency Performance. The NERC Reliability Standards apply not only to interconnected system operation but also to individual service areas (NERC Ongoing).
- California ISO Planning Standards also provide standards and guidelines to assure the adequacy, security and reliability in the planning of the California ISO transmission grid facilities. The California ISO Grid Planning Standards incorporate the NERC/WECC and NERC Reliability Planning Standards. With regard to power flow, stability simulations, Special Protection Systems and Load Interruption Standards, these Planning Standards are similar to the NERC/WECC or NERC Reliability Planning Standards for Transmission System Contingency Performance. However, the California ISO Standards also provide some additional requirements that are not address in the NERC / WECC standards, provide interpretations of the NERC/WECC criteria specific to the ISO grid, and identify whether specific criteria should be adopted. The California ISO Standards apply to all participating transmission owners interconnecting to the California ISO controlled grid. They also apply when there are any impacts to the California ISO grid due to facilities interconnecting to adjacent controlled grids not operated by the California ISO. The California ISO standards will be revised from time to time to ensure they are consistent with the current state of the electrical industry and in conformance with NERC Reliability Standards and WECC Regional Criteria (California ISO June, 23 2011).
- California ISO/FERC Electric Tariff provides guidelines for construction of all transmission additions/upgrades (projects) within the California ISO controlled grid. The California ISO determines the "Need" for the proposed modified project where it will promote economic efficiency or maintain system reliability. The California ISO also determines the Cost Responsibility of the proposed modified project and provides an Operational Review of all facilities that are to be connected to the California ISO grid (California ISO 2007a).

PROJECT DESCRIPTION

Palen Solar I, LLC originally proposed to construct, own and operate the PSPP. The original proposed project would be a concentrated solar thermal electric generating facility with two adjacent solar plants. Each solar generating plant would use a 300 MVA steam turbine generating unit for a combined net output of 530 MW. The project's planned operational date was summer 2013.

Generating Unit 1 requires a 9,200 foot long transmission line to the PSPP switchyard and Generating Unit 2 requires a 4,000 foot long transmission line. Each line would be connected to a common bus segment at the PSPP switchyard. The PSPP power would be transmitted from the PSPP switchyard to the SCE Red Bluff substation via an 8 mile long double circuit 230 kV transmission line. (PSPP 2009b, section 1.0, 2.6 and Figures 2.9, 2-14, 2-15, 2-16)

Palen Solar Holdings, LLC currently proposes to amend the original licensed PSPP and change the name to PSEGS. The proposed PSEGS project would be a solar thermal electric generating facility with two solar plants. Each solar generating plant would consist of a solar field and a power block. The PSEGS would uses heliostats to focus sun rays on a solar receiver steam generator (SRSG). The steam turbine generator (STG) will receive steam from the SRSG to generate electricity.

Each solar generating plant would have a steam turbine unit rated at 317 MVA with a power factor of 0.90, resulting in a maximum power output of 285 MW. For two solar generating plants, the maximum output would be 570 MW. Approximately 22 MW of the generating power would be used for auxiliary load. Thus, although the project owner has applied to the California ISO and the Energy Commission for only 500 MW of generation, the PSEGS could generate up to 548 MW. The project's planned operational date is approximately be the end of June 2016.

The STG would be connected through a 21 kV 10,000-ampere generator circuit breaker via a short 10,000-ampere isolated phase bus duct to the low side of its dedicated 190/253/315 MVA generator step-up (21/230 kV) transformer. The auxiliary power for each unit would be provided through its dedicated back-fed transformer (21/4.16/13.8 kV) which is connected between the STG circuit breaker and the low side of the step-up transformer through 10,000-ampere isolated phase bus duct.

For each generating unit, the 230 kV side of its step-up transformer would be connected through a 230 kV, 1,200 ampere disconnect switch and a 230 kV underground cable (XLPE copper cable between 1,250 kcmil and 1,750 kcmil) to the 230 kV project switchyard. Generating Unit 1 requires a 6,234 foot long underground cable to the project switchyard and Generating Unit 2 requires a 14,586 foot long underground cable. Each line would be connected to a common bus segment at the Palen project switchyard. The proposed Palen switchyard would consist of a 2,000 amps 230 kV circuit breaker, two 2,000 amps 230 kV disconnect switches and protection circuits (Palen 2012 A, section 2.1.3, 2.2.2, section 3.2.2 Figure 3.2-1, Figures 3.2-2, Palen 2013l).

SWITCHYARDS AND INTERCONNECTION FACILITIES

Power generated by the PSEGS would be transmitted from the project switchyard to the proposed SCE 500/230 kV Red Bluff substation via a 6.9 mile long single circuit 230 kV transmission line. The single circuit line would be built with twin-bundled, 795 kcmil conductors which are capable of carrying 1,814 amps at 75 degrees centigrade. The proposed overhead generator transmission line is rated to carry the full capacity of the 548 MW PSEGS. The 230 kV transmission line would be supported by mono-pole structures at approximately 1,100 foot intervals, and the final pole height would be determined during the detailed design phase of the transmission facilities. The applicant has proposed to extend the bus work within the breaker-and–a-half Red Bluff substation to interconnect the solar plant. The modification of the Red Bluff substation would consist of one new 230 kV 3,000 amp circuit breaker, and two 230 kV 3,000 amp disconnect switches. SCE and the applicant agreed to connect the PSEGS switchyard to the proposed Red Bluff 500/230 kV substation. Power would be distributed to the grid via transmission lines connected to the Red Bluff substation (Palen 2012a, section 2.1.3, 2.2.2, Figures 3.2-2, Palen 2013l, Palen 2013n).

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

For the interconnection of a proposed generating unit or transmission facility to the grid, the interconnecting utility and the control area operator are responsible for ensuring grid reliability. For the PSEGS, SCE and the California ISO are responsible for ensuring grid reliability.

The California ISO's generator interconnection study process is in transition from a serial process to an interconnection window cluster study process. The PSPP was studied under the window cluster process and the transmission reliability impacts of the proposed modified project were studied in the Phase I and Phase II Studies. The Phase I Study is similar to the former System Impact Study except it is now performed for a group of projects in the same geographical area of a utility that apply for interconnection in the same request window. The Phase II Study (former Facilities Study) is performed after generators in each cluster meet specific milestones required to stay in the generator interconnection queue. The Phase II Study is then performed based on the number of generators left in each cluster.

The Phase I and Phase II Studies for projects in the transition cluster were conducted to determine the preferred and alternative generator interconnection methods, and to identify any mitigation measures required to ensure system conformance with utility reliability criteria, NERC planning standards, WECC reliability criteria, and California ISO reliability criteria. Staff relies on the studies and any review conducted by the responsible agencies to determine the effect of the projects on the transmission grid and to identify any necessary downstream facilities or indirect project impacts required to bring the transmission network into compliance with applicable reliability standards (NERC 2006, WECC 2006, California ISO 2002a, 2007a & 2009a).

The Phase II Study analyzed the grid with and without the generator or generators in the cluster under conditions specified in the planning standards and reliability criteria. The standards and criteria defined the assumptions used in the study and established the thresholds by which grid reliability was determined. The studies must analyze the impact of the projects for their proposed first year(s) of operation and thus were based on a forecast of loads, generation and transmission. Load forecasts were developed by the interconnected utility, which was SCE in this case. Generation and transmission forecasts were based on the interconnection queue. The studies focused on thermal overloads, voltage deviations, system stability (excessive oscillations in generators and transmission system, voltage collapse, loss of loads or cascading outages), short circuit duties and substation evaluation.

Under the new California ISO LGIP, generators are able to choose between either “full capacity” or “energy only”, depending on whether or not the generator wants to have the right to generate energy 24 hours per day. A generator that chooses the full capacity option will be required to pay for transmission network upgrades that are needed to allow the generator to operate under virtually any system conditions and as such could sign contracts that allow them to provide capacity to utilities. Energy only generators would not pay for network transmission upgrades, and essentially would have access to as available transmission capacity, and would likely not be able to sign capacity contracts.

If the studies show that the interconnection of the project or cluster of projects causes the grid to be out of compliance with reliability standards, the study will then identify mitigation alternatives or ways in which the grid could be brought into compliance with reliability standards. If the interconnecting utility determines that the only feasible mitigation includes transmission modifications or additions that require CEQA review as part of the “whole of the action,” the Energy Commission must analyze those modifications or additions according to CEQA requirements. Where the Phase II Study identifies transmission modifications required for the reliable interconnection of a cluster of generators, staff will analyze the proposed generating project’s impact on individual reliability criteria violations to determine whether or not the identified mitigation measures are a reasonably foreseeable consequence of the proposed modified project.

SCOPE OF THE TRANSITION CLUSTER PHASE I AND PHASE II INTERCONNECTION STUDIES

The July 28, 2009, Transition Cluster Phase I Interconnection Study was prepared by the California ISO in coordination with SCE. Fifteen queue generation projects, including the proposed 500 MW PSPP in the Eastern Riverside County area with a total of 10,040 MW net generation output, were included in this cluster study. As of December 4, 2009 only five projects (2,200 MW) of the original 15 projects remained in the interconnection queue. Reducing the size of the cluster by 10 projects and over 7,000 MW meant the Phase 1 Study results for the cluster were not a reasonable forecast of the reliability impacts of the proposed modified project.

Generally staff relies on the California ISO Phase I/SIS to determine whether or not the proposed generation project will likely comply with reliability and to identify the transmission facilities required for reliable interconnection. For the Transition Cluster projects, the Phase I Study did not provide an accurate forecast of impacts of the PSPP on the SCE transmission grid. Therefore, staff has relied on the Phase II Group Study that was completed on July 8, 2010 and received on July 23, 2010, to determine the PSEGS impact on grid reliability and identify transmission upgrades for reliable interconnection.

The changes between the Transition Cluster Phase I and Phase II Studies for the Eastern Bulk System, included the withdrawal of ten generation projects totaling 7,490 MW, changing the point of interconnection of one generation project, and a reduction of 350 MW of generation from two projects. For study purposes, five generation projects totaling a maximum output of 2,200 MW were included in the SCE Transition Cluster base cases. During the study, three of these projects, PSPP, the Blythe Solar Power Project and the Genesis Solar Energy Project were seeking licenses from the California Energy Commission.

The Phase II Group Study modeled the PSPP with a net output of 500 MW. The base case was developed from WECC's 2013 Peak load and 2013 Off-Peak load base case series and included all major SCE transmission projects, and all proposed higher queued generation projects that will be operational by 2013. The Phase II Group Study pre-project base cases were modeled to include the Devers–Colorado River project (DCR), which is the California portion of Devers–Palo Verde 2 (DPV2), and the proposed 500 kV switchyard at Colorado River substation. The power flow studies were conducted with and without the proposed Transition Cluster Phase II projects connected to the SCE grid at each project's interconnection switchyard. The detailed study assumptions were described in the study. The power flow study assessed the Transition Cluster Phase II projects impact on thermal loading of the transmission lines and equipments. Transient and post-transient studies were conducted using the Peak load full loop base case to determine whether the Transition Cluster Phase II projects would create instability in the system following certain selected outages. Short circuit studies were conducted to determine if the Transition Cluster Phase II projects would overstress existing substation facilities. (Cal ISO 2010a)

PHASE II STUDY RESULTS FOR TRANSITION CLUSTER PROJECTS

Power Flow Study Results and Mitigation Measures

The Phase II Group Study identified pre-project overload criteria violations under 2013 Summer Peak and Off-Peak study condition. Pre-project overloads are caused by either existing system conditions or by projects with higher positions in the SCE's generator interconnection queue. The study concluded that the addition of the Phase II Transition Cluster projects would cause a number of pre-existing normal and /or emergency overloads to increase and would cause some new normal and emergency overloads (Cal ISO 2010a).

Results of the Phase II Group Study are detailed below. Where potential overloads were identified, mitigation was proposed to eliminate the potential reliability impact.

Normal Overloads (N-0)

The power flow study indicated that the Phase II Transition Cluster projects would cause three normal overloads under 2013 Peak load conditions and Off-Peak load conditions. The predicted overload facilities were the same for both Peak and Off-Peak load conditions.

Overloaded Transmission Facilities:

- Devers–San Bernardino 220 kV No. 1 line
- Devers–San Bernardino 220 kV No. 2 line
- Devers-Vista 220 kV No. 1 line

Recommended Mitigation:

A combination of congestion management for base case and contingency overloads, the West-of-Devers upgrade project, and the looping the 2nd Colorado River–Devers 500 kV transmission line into the Red Bluff substation are required to mitigate the power flow impacts caused by the project. The detailed electrical facilities needed to mitigate the overload criteria violations have been addressed and selected in the group report in SCE’s Eastern Bulk System.

Category B (N-1)

The power flow study indicated that the Phase II Transition Cluster projects would cause four N-1 overloads under 2013 Peak load conditions and Off-Peak load conditions. The predicted overload facilities were the same for both Peak and Off-Peak load conditions.

Overloaded Transmission Facilities:

- Devers–San Bernardino 230 kV No. 1 line
- Devers–San Bernardino 230 kV No. 2 line
- Devers-Vista 230 kV No. 1 line
- Devers-Vista 230 kV No. 2 line

Recommended Mitigation:

A combination of congestion management for base case and contingency overloads, the West-of-Devers upgrade project, and the looping the 2nd Colorado River–Devers 500 kV transmission line into the Red Bluff substation are required to mitigate the power flow impacts caused by the project. The detailed electrical facilities needed to mitigate the overload criteria violations have been addressed and selected in the group report in SCE’s Eastern Bulk System.

Category C (N-2)

The power flow study indicated that the Phase II Transition Cluster projects would cause five new N-2 overloads under 2013 Peak load conditions and Off-Peak load conditions. The three predicted overload facilities were the same for both Peak and Off-Peak load conditions. Additionally one new overload was revealed.

Overloaded Transmission Facilities:

- Devers–San Bernardino 220 kV No. 1 line
- Devers–San Bernardino 220 kV No. 2 line
- Devers-Vista 220 kV line No. 1 line
- Devers-Vista 220 kV No. 2 line
- Mira Loma–Vista 220 kV No. 2 line

Recommended Mitigation:

A combination of congestion management, the West-of-Devers upgrade project, and the looping the 2nd Colorado River–Devers 500 kV transmission line into the Red Bluff substation are required to mitigate the power flow impacts caused by the project. The detailed electrical facilities needed to mitigate the overload criteria violations have been addressed and selected in the group report in SCE's Eastern Bulk System.

Transient Stability Study Results and Mitigation Measures

Transient stability studies were conducted using the full loop base cases to ensure that the transmission system remained in operating equilibrium, as well as operating in a coordinated fashion, through abnormal operating conditions after the Phase II Transition Cluster projects became operational. Disturbance simulations were performed for a study period of 10 seconds to determine whether the Phase II Transition Cluster projects would create any system instability during line and generator outages. All outage cases were evaluated with the assumption that existing Special Protection Systems (SPS) or Remedial Action Schemes (RAS) would operate as designed. The most critical single contingency and double contingency outage conditions in the east and west of Devers area within the overall SCE Eastern Bulk System were evaluated. The transient study identified system instability during the N-2 outages. Therefore, an SPS has been proposed as a mitigation measure that will curtail the 1,400 MW of generation of the Phase II Transition Cluster projects. The proposed PSEGS project has been included in rearming the SPS. (Transition Cluster Phase II Interconnection Study Report, SCE's Eastern Bulk System, Appendix F Dynamic Stability Plots)

Reactive Power Deficiency Analysis Results

Reactive power deficiency analysis was performed in the group study. The reactive power deficiency analysis included power flow sensitivity analysis in the Eastern Bulk System. The study found no reactive deficiency from this PSEGS project to the SCE bulk system.

Short Circuit Study Results and Mitigation Measures

Short circuit studies were performed to determine the degree to which the addition of the Phase II Transition Cluster projects would increase fault duties at SCE's substations, adjacent utility substations, and the other 115 kV, 230 kV and 500 kV busses within the study area. The fault duties were calculated with and without the Phase II Transition Cluster projects to identify any equipment overstress conditions. All bus locations where the Phase II Transition Cluster projects increased the short circuit duty by 0.1 kA or more and where the short circuit duty was in excess of 60% of the minimum breaker nameplate rating are listed in Appendix H of the Transition Cluster Phase II Interconnection Study Report, SCE's Eastern Bulk System. With the addition of the Transition Cluster Phase II projects, the following overstressed circuit breakers were identified at the following substations: Vincent 500 kV substation – 11 breakers, Kramer 220 kV substation – 5 breakers, Windhub 220 kV substation – 9 breakers, and Antelope 66 kV substation – 2 breakers. Mitigation measures included the following:

- Vincent 500 kV substation: replace seven circuit breakers and upgrade four circuit breakers
- Kramer 220 kV substation: replace five circuit breakers
- Windhub 220 kV substation: sectionalize 220 kV bus
- Antelope 66 kV substation: operating procedure to reduce short circuit duty

CUMULATIVE IMPACTS

Staff has reviewed the list of existing and foreseeable projects as presented in the Cumulative Scenario section of this analysis. Staff's review considers whether the interconnection of PSEGS to SCE's transmission system along with other existing and foreseeable generation projects would conform to all LORS required for safe and reliable electric power transmission. The analysis described above under the heading Scope of the Transition Cluster Phase I and Phase II Interconnection Studies is conducted in coordination with, and with the approval of, the California ISO to consider existing and proposed generator interconnections to the transmission grid and the potential safety and reliability impacts under a number of conservative contingency conditions.

The cumulative marginal impacts to the safe and reliable operation of the transmission system due to the PSPP project, as identified in the Phase II Study, would be mitigated with the Energy Commission's and BLM's incorporation of the mitigation measures and Conditions of Certification set forth in this section.

COMPLIANCE WITH LORS

The proposed interconnection facilities including the PSEGS 230 kV project switchyard, generator 230 kV overhead tie line to the new SCE Red Bluff 230 kV substation, and its termination at the new 230 kV substation are adequate in accordance with industry standards and good utility practices, and are acceptable to staff. Staff believes that existing Conditions of Certification **TSE-1** through **TSE-7** will ensure the proposed PSEGS complys with applicable LORS:

1. Condition of Certification **TSE-1** will ensure that the preliminary equipment is in place for construction of the transmission facilities of the proposed project to comply with applicable LORS.

2. Condition of Certification **TSE-2** will ensure that the proper personnel are ready to manage and monitor the construction of the transmission facilities for the proposed project to comply with applicable LORS.

3. Condition of Certification **TSE-3** will ensure that any changes to the proposed transmission facilities would comply with applicable LORS.

4. Condition of Certification **TSE-4** will ensure that the final design of the proposed transmission facilities would comply with applicable LORS.

5. Condition of Certification **TSE-5** will ensure that the proposed project would be properly interconnected to the transmission grid. **TSE-5** also ensures that the generator output would be properly delivered to the transmission system.

6. Condition of Certification **TSE-6** will ensure that the project would synchronize with the existing transmission system and the operation of the facilities would comply with applicable LORS.

7. Condition of Certification **TSE-7** will ensure that the proposed project has been built to required specifications and the operation of the facilities would comply with applicable LORS.

The Phase II Interconnection Study indicates that the project interconnection would comply with all NERC/WECC planning standards and California ISO reliability criteria as long as the identified Reliability Network Upgrades are implemented.

RESPONSE TO COMMENTS

Staff received no comments relating to **Transmission System Engineering**.

CONCLUSIONS

The proposed PSEGS amendment project has no substantial changes to TSE compared to the original licensed PSPP. Except for the change in generation technology, the generation output and the interconnection facilities remain unchanged. No new conditions or changes to conditions of certification are required.

The proposed interconnection facilities including the PSEGS 230 kV project switchyard, the 230 kV overhead generator tie-line, and its termination at the new SCE Red Bluff substation, are acceptable and would comply with applicable LORS.

California ISO approved PSEGS's conversion to solar tower from the original PSPP parabolic trough field technology. The California ISO's Transition Cluster Phase I and Phase II Interconnection Study Reports for the PSPP are applicable to the PSEGS.

The California ISO Phase II Study Report – Group Report in SCE's Eastern Bulk System indicates the reliable interconnection and delivery of projects in the Eastern bulk system, which includes the PSEGS, would require the following upgrades to the existing or planned SCE transmission system:

- Replacement or upgrade of many circuit breakers at substations in the SCE system. Circuit breaker replacement generally occurs within the fence line of existing substation facilities.
- The use of new or expanded SPS. These are essentially operating procedures that reduce the output of generators under specific conditions in order to avoid overloading transmission equipment.
- Reconductor of the drops of the Mira Loma–Vista 220 kV transmission line at the Vista substation. The "drops" are the portion of the line that comes into the substation.
- The West of Devers upgrades, including reconductoring and relocation of four 220 kV transmission lines west of the Devers substation, have been identified in SCE transmission plans for several years starting in 2007 as needed to reliably serve future loads in the SCE service area and would therefore be needed to maintain system reliability even if the Eastern Bulk System generators were not constructed. Also, based on the SCE Devers-Palo Verde #2 Project upgrade timeline, the construction of the Red Bluff substation and looping the 2nd Colorado River–Devers 500 kV transmission line into the proposed Red Bluff substation is expected to be operational by 3rd quarter of 2013.

PROPOSED CONDITIONS OF CERTIFICATIONS

Staff has no proposed changes to the existing Conditions of Certification as provided below.

TSE-1 The project owner shall furnish to the CPM and to the CBO a schedule of transmission facility design submittals, a Master Drawing List, a Master Specifications List, and a Major Equipment and Structure List. The schedule shall contain a description and list of proposed submittal packages for design, calculations, and specifications for major structures and equipment. To facilitate audits by Energy Commission staff, the project owner shall provide designated packages to the CPM when requested.

Verification: Prior to the start of construction of the transmission facilities, the project owner shall submit the schedule, a Master Drawing List, and a Master Specifications List to the CBO and to the CPM. The schedule shall contain a description and list of proposed submittal packages for design, calculations, and specifications for major structures and equipment (see a list of major equipment below). Additions and deletions shall be made to the table only with CPM and CBO approval. The project owner shall provide schedule updates in the Monthly Compliance Report.

Breakers
Step-up transformer
Switchyard
Busses
Surge arrestors
Disconnects
Take-off facilities
Electrical control building
Switchyard control building
Transmission pole/tower
Grounding system

TSE-2 Before the start of construction, the project owner shall assign to the project an electrical engineer and at least one of each of the following:

a) a civil engineer;

b) a geotechnical engineer or a civil engineer experienced and knowledgeable in the practice of soils engineering;

c) a design engineer who is either a structural engineer or a civil engineer and fully competent and proficient in the design of power plant structures and equipment supports; or

d) a mechanical engineer (Business and Professions Code Sections 6704 et seq. require state registration to practice as either a civil engineer or a structural engineer in California).

The tasks performed by the civil, mechanical, electrical, or design engineers may be divided between two or more engineers as long as each engineer is responsible for a particular segment of the project, e.g., proposed earthwork, civil structures, power plant structures, or equipment support. No segment of the project shall have more than one responsible engineer. The transmission line may be the responsibility of a separate California registered electrical engineer. The civil, geotechnical, or civil and design engineer, assigned as required by **Facility Design** Condition **GEN-5**, may be responsible for design and review of the TSE facilities.

The project owner shall submit to the CBO, for review and approval, the names, qualifications, and registration numbers of all engineers assigned to the project. If any one of the designated engineers is subsequently reassigned or replaced, the project owner shall submit the name, qualifications, and registration number of the newly assigned engineer to the CBO for review and approval. The project owner shall notify the CPM of the CBO's approval of the new engineer. This engineer shall be authorized to halt earth work and require changes; if site conditions are unsafe or do not conform to the predicted conditions used as the basis for design of earth work or foundations.

The electrical engineer shall:

1. be responsible for the electrical design of the power plant switchyard, outlet, and termination facilities; and

2. sign and stamp electrical design drawings, plans, specifications, and calculations.

Verification: Prior to the start of rough grading, the project owner shall submit to the CBO for review and approval, the names, qualifications, and registration numbers of all the responsible engineers assigned to the project. The project owner shall notify the CPM of the CBO's approvals of the engineers within five days of the approval.

If the designated responsible engineer is subsequently reassigned or replaced, the project owner has five days in which to submit the name, qualifications, and registration number of the newly assigned engineer to the CBO for review and approval. The project owner shall notify the CPM of the CBO's approval of the new engineer within five days of the approval.

TSE-3 If any discrepancy in design and/or construction is discovered in any engineering work that has undergone CBO design review and approval, the project owner shall document the discrepancy and recommend corrective action (2001 California Building Code, Chapter 1, section 108.4, approval required; Chapter 17, section 1701.3, *Duties and Responsibilities of the Special Inspector;* Appendix Chapter 33, section 3317.7, *Notification of Noncompliance*). The discrepancy documentation shall become a controlled document and shall be submitted to the CBO for review and approval and refer to this condition of certification.

Verification: The project owner shall submit a copy of the CBO's approval or disapproval of any corrective action taken to resolve a discrepancy to the CPM within 15 days of receipt. If disapproved, the project owner shall advise the CPM, within five days, the reason for the disapproval, along with the revised corrective action required to obtain the CBO's approval.

TSE-4 For the power plant switchyard, outlet line and termination, the project owner shall not begin any construction until plans for that increment of construction have been approved by the CBO. These plans, together with design changes and design change notices, shall remain on the site for one year after completion of construction. The project owner shall request that the CBO inspect the installation to ensure compliance with the requirements of applicable LORS. The following activities shall be reported in the monthly compliance report:

a) receipt or delay of major electrical equipment;

b) testing or energization of major electrical equipment; and

c) the number of electrical drawings approved, submitted for approval, and still to be submitted.

Verification: Prior to the start of each increment of construction, the project owner shall submit to the CBO for review and approval the final design plans, specifications and calculations for equipment and systems of the power plant switchyard, and outlet line and termination, including a copy of the signed and stamped statement from the responsible electrical engineer verifying compliance with all applicable LORS, and send the CPM a copy of the transmittal letter in the next monthly compliance report.

TSE-5 The project owner shall ensure that the design, construction, and operation of the proposed transmission facilities will conform to all applicable LORS, and the requirements listed below. The project owner shall submit the required number of copies of the design drawings and calculations, as determined by the CBO. Once approved, the project owner shall inform the CPM and CBO of any anticipated changes to the design, and shall submit a detailed description of the proposed change and complete engineering, environmental, and economic rationale for the change to the CPM and CBO for review and approval.

a) The power plant outlet line shall meet or exceed the electrical, mechanical, civil, and structural requirements of CPUC General Order 95 or National Electric Safety Code (NESC); Title 8 of the California Code and Regulations (Title 8); Articles 35, 36 and 37 of the *High Voltage Electric Safety Orders*, California ISO standards, National Electric Code (NEC) and related industry standards.

b) Breakers and busses in the power plant switchyard and other switchyards, where applicable, shall be sized to comply with a short-circuit analysis.

c) Outlet line crossings and line parallels with transmission and distribution facilities shall be coordinated with the transmission line owner and comply with the owner's standards.

d) The project conductors shall be sized to accommodate the full output of the project.

e) Termination facilities shall comply with applicable SCE interconnection standards.

f) The project owner shall provide to the CPM:

   i) The Special Protection System (SPS) sequencing and timing if applicable,

   ii) A letter stating that the mitigation measures or projects selected by the transmission owners for each reliability criteria violation, for which the project is responsible, are acceptable, and

   iii) A copy of the executed LGIA signed by the California ISO and the project owner.

Verification: Prior to the start of construction or start of modification of transmission facilities, the project owner shall submit to the CBO for approval:

1. Design drawings, specifications, and calculations conforming with CPUC General Order 95 or National Electric Safety Code (NESC); Title 8 of the California Code and Regulations (Title 8); Articles 35, 36 and 37 of the *High Voltage Electric Safety Orders*, California ISO standards, National Electric Code (NEC) and related industry standards, for the poles/towers, foundations, anchor bolts, conductors, grounding systems, and major switchyard equipment;

2. For each element of the transmission facilities identified above, the submittal package to the CBO shall contain the design criteria, a discussion of the calculation method(s), a sample calculation based on "worst case conditions"[1] and a statement signed and sealed by the registered engineer in responsible charge, or other acceptable alternative verification, that the transmission element(s) will conform with CPUC General Order 95 or National Electric Safety Code (NESC); Title 8 of the California Code and Regulations (Title 8); Articles 35, 36 and 37 of the *High Voltage Electric Safety Orders*, California ISO standards, National Electric Code (NEC), and related industry standards;

3. Electrical one-line diagrams signed and sealed by the registered professional electrical engineer in charge, a route map, and an engineering description of the equipment and configurations covered by requirements **TSE-5** a) through f);

4. The Special Protection System (SPS) sequencing and timing if applicable shall be provided concurrently to the CPM.

[1] Worst-case conditions for the foundations would include for instance, a dead-end or angle pole.

5. A letter stating that the mitigation measures or projects selected by the transmission owners for each reliability criteria violation, for which the project is responsible, are acceptable, and

6. A copy of the executed LGIA signed by the California ISO and the project owner.

Prior to the start of construction of or modification of transmission facilities, the project owner shall inform the CBO and the CPM of any anticipated changes to the design that are different from the design previously submitted and approved and shall submit a detailed description of the proposed change and complete engineering, environmental, and economic rationale for the change to the CPM and CBO for review and approval.

TSE-6 The project owner shall provide the following Notice to the California Independent System Operator (California ISO) prior to synchronizing the facility with the California Transmission system:

1. At least one week prior to synchronizing the facility with the grid for testing, provide the California ISO a letter stating the proposed date of synchronization; and

2. At least one business day prior to synchronizing the facility with the grid for testing, provide telephone notification to the California ISO Outage Coordination Department.

<u>Verification:</u> The project owner shall provide copies of the California ISO letter to the CPM when it is sent to the California ISO one week prior to initial synchronization with the grid. The project owner shall contact the California ISO Outage Coordination Department, Monday through Friday, between the hours of 0700 and 1530 at (916) 351-2300 at least one business day prior to synchronizing the facility with the grid for testing. A report of conversation with the California ISO shall be provided electronically to the CPM one day before synchronizing the facility with the California transmission system for the first time.

TSE-7 The project owner shall be responsible for the inspection of the transmission facilities during and after project construction, and any subsequent CPM and CBO approved changes thereto, to ensure conformance with CPUC GO-95 or NESC, Title 8, CCR, Articles 35, 36 and 37 of the, “High Voltage Electric Safety Orders”, applicable interconnection standards, NEC and related industry standards. In case of non-conformance, the project owner shall inform the CPM and CBO in writing, within 10 days of discovering such non-conformance and describe the corrective actions to be taken.

<u>Verification:</u> Within 60 days after first synchronization of the project, the project owner shall transmit to the CPM and CBO:

1. “As built” engineering description(s) and one-line drawings of the electrical portion of the facilities signed and sealed by the registered electrical engineer in responsible charge. A statement attesting to conformance with CPUC GO-95 or NESC, Title 8, California Code of Regulations, Articles 35, 36 and 37 of the “High Voltage Electric Safety Orders”, and applicable interconnection standards, NEC, related industry standards.

2. An “as built” engineering description of the mechanical, structural, and civil portion of the transmission facilities signed and sealed by the registered engineer in responsible charge or acceptable alternative verification. “As built” drawings of the electrical, mechanical, structural, and civil portion of the transmission facilities shall be maintained at the power plant and made available, if requested, for CPM audit as set forth in the “Compliance Monitoring Plan”.

3. A summary of inspections of the completed transmission facilities, and identification of any nonconforming work and corrective actions taken, signed and sealed by the registered engineer in charge.

DEFINITION OF TERMS

ACSR .... Aluminum cable steel reinforced.

AAC .... All Aluminum conductor.

ACSS .... Aluminum conductor steel-supported.

Ampacity .... Current-carrying capacity, expressed in amperes, of a conductor at specified ambient conditions, at which damage to the conductor is nonexistent or deemed acceptable based on economic, safety, and reliability considerations.

Ampere .... The unit of current flowing in a conductor.

Kiloampere (kA) .... 1,000 Amperes

Bundled .... Two wires, 18 inches apart.

Bus .... Conductors that serve as a common connection for two or more circuits.

Conductor .... The part of the transmission line (the wire) that carries the current.

Congestion .... Congestion management is a scheduling protocol, which provides that

Management .... dispatched generation and transmission loading (imports) would not violate criteria.

Emergency Overload . See Single Contingency. This is also called an L-1.

Hertz .... The unit for System Frequency.

Kcmil or KCM .... Thousand circular mil. A unit of the conductor’s cross sectional area, when divided by 1,273, the area in square inches is obtained.

Kilovolt (kV) .... A unit of potential difference, or voltage, between two conductors of a circuit, or between a conductor and the ground. 1,000 Volts.

Loop .... An electrical cul de sac. A transmission configuration that interrupts an existing circuit, diverts it to another connection and returns it back to the interrupted circuit, thus forming a loop or cul de sac.

MVAR or .... Megavolt Ampere-Reactive. One million Volt-Ampere-Reactive.

Megavars.................... Reactive power is generally associated with the reactive nature of motor loads that must be fed by generation units in the system.

Megavolt..................... A unit of apparent power, equals the product of the line voltage

Ampere (MVA) .... in kilovolts, current in amperes, the square root of 3, and divided by 1000.

Megawatt (MW) .... A unit of power equivalent to 1,341 horsepower.

Normal Operation/Normal Overload

When all customers receive the power they are entitled to without interruption and at steady voltage, and no element of the transmission system is loaded beyond its continuous rating.

N-1 Condition............. See Single Contingency.

Outlet.......................... Transmission facilities (circuit, transformer, circuit breaker, etc.) linking generation facilities to the main grid.

Power Flow Analysis . A power flow analysis is a forward looking computer simulation of essentially all generation and transmission system facilities that identifies overloaded circuits, transformers and other equipment and system voltage levels.

Reactive Power.......... Reactive power is generally associated with the reactive nature of inductive loads like motor loads that must be fed by generation units in the system. An adequate supply of reactive power is required to maintain voltage levels in the system.

Remedial Action .... A remedial action scheme is an automatic control provision,

Scheme (RAS) .... which, for instance, would trip a selected generating unit upon a circuit overload.

SSAC .... Steel Supported Aluminum Conductor.

SF6.............................. Sulfur hexafluoride is an insulating medium.

Single .... Also known as emergency or N-1 condition, occurs when one

Contingency .... major transmission element (circuit, transformer, circuit breaker, etc.) or one generator is out of service.

Solid Dielectric .... Copper or aluminum conductors that are insulated by solid

Cable polyethylene type insulation and covered by a metallic shield and outer polyethylene jacket.

SVC............................. Static VAR Compensator: An equipment made of Capacitors and Reactors with electronic controls for producing and controlling Reactive Power in the Power System.

Switchyard................. A power plant switchyard (switchyard) is an integral part of a power plant and is used as an outlet for one or more electric generators.

Thermal rating........... See ampacity.

TSE............................. Transmission System Engineering.

TRV............................. Transient Recovery Voltage

Tap.............................. A transmission configuration creating an interconnection through a sort single circuit to a small or medium sized load or a generator. The new single circuit line is inserted into an existing circuit by utilizing breakers at existing terminals of the circuit, rather than installing breakers at the interconnection in a new switchyard.

Undercrossing........... A transmission configuration where a transmission line crosses below the conductors of another transmission line, generally at 90 degrees.

Underbuild................. A transmission or distribution configuration where a transmission or distribution circuit is attached to a transmission tower or pole below (under) the principle transmission line conductors.

VAR............................. Voltage Ampere Reactive, a measure for Reactive power in the power system.

ALTERNATIVES

Testimony of Jeanine Hinde[1]

INTRODUCTION

This analysis evaluates a reasonable range of potentially feasible alternatives to the proposed Palen Solar Electric Generating System (PSEGS), also referred to as the proposed modified project in this staff assessment.

Staff reviewed the previous alternatives analysis for the licensed Palen Solar Power Project (PSPP) during the initial work to determine the scope of the analysis for the proposed modified project. The alternatives analysis for the PSPP retained three reconfigured alternatives, a reduced acreage alternative, and one off-site alternative for detailed analysis and comparison to the PSPP. Of the three reconfigured alternatives, the Commission Decision for the PSPP determined that Reconfigured Alternatives #2 and #3 would reduce impacts on Mojave fringe-toed lizard, sand dune habitat, and the sand transport corridor (California Energy Commission 2010a). Staff biologists identified mitigation measures that would reduce impacts on terrestrial wildlife species and sensitive habitats to less than significant for the two reconfigured alternatives. The Commission Decision approved construction and operation of either Reconfigured Alternative #2 or #3 using the parabolic trough technology proposed for the PSPP. No alternatives using other solar technologies were retained for detailed analysis in the previous alternatives analysis.

The proposed modified project would use BrightSource Energy's solar power tower (SPT) technology. Staff has selected three project alternatives for full analysis and comparison to the proposed modified project:

- No-Project Alternative
- Solar Photovoltaic Alternative with Single-Axis Tracking Technology
- Reduced Acreage Alternative with Solar Power Tower Technology

The PSEGS site was previously approved for development of a 500-megawatt (MW) parabolic trough project; therefore, construction and operation of a parabolic trough project at the approved site is a reasonably foreseeable outcome for use of the site should plans for the proposed modified project fail to proceed. For PSEGS, the No-Project Alternative evaluates the impacts of the proposed modified project compared to the impacts of constructing and operating either of the approved alternatives from the original PSPP.

[1] **Alternatives Appendix-1** lists other staff contributors to this analysis of project alternatives.

The Solar Photovoltaic (PV) Alternative would involve constructing and operating a utility-scale PV project using single-axis tracking technology at the PSEGS site with no change to the site boundary. The Reduced Acreage Alternative with Solar Power Tower (SPT) Technology would retain the solar tower unit and heliostat array from PSEGS Unit 1 (the western solar field), and it would include approximately 70 acres from the inside edge of PSEGS Unit 2 (the eastern solar plant) for a total of approximately 1,742 acres. Each of these alternatives is described below, under "Alternatives Evaluated in Detail."

The subsection below, "Alternatives Considered in the Previous Analysis for the PSPP," summarizes the off-site alternatives considered in the previous alternatives analysis.

Staff concludes that constructing and operating Reconfigured Alternative #2 or #3 (i.e., the No-Project Alternative) would avoid or substantially reduce certain impacts on **Biological Resources**, **Cultural Resources**, and **Visual Resources**. For impacts on **Biological Resources**, staff concludes that impacts on the sand transport corridor, sand dunes, and the Mojave fringe-toed lizard would be "somewhat less than PSEGS." Staff identifies a potentially significant impact on avian species that could remain *significant and unavoidable* even after mitigation. For impacts on **Visual Resources**, staff identifies a *significant and unavoidable* impact from glint and glare effects of the high-profile solar receiver steam generators. These two impacts would not occur with construction and operation of Reconfigured Alternative #2 or #3:

- **Biological Resources** – Potential impacts on avian species from exposure to concentrated solar flux.
- **Visual Resources** – Glint or glare effects from high-profile solar receiver steam generators.

If reducing or avoiding several direct and indirect environmental impacts is a critical factor, then either Reconfigured Alternative #2 or #3 would be environmentally superior to the proposed modified project.

Staff concludes that constructing and operating the Solar PV Alternative with Single-Axis Tracking Technology would avoid or substantially reduce several impacts on **Biological Resources**, **Cultural Resources**, **Traffic and Transportation**, and **Visual Resources**.

Without the SPTs, three impacts identified by staff as *potentially significant* or *significant and unavoidable* under the proposed modified project would not occur with construction and operation of the Solar PV Alternative:

- **Biological Resources** – Potential impacts on avian species from exposure to concentrated solar flux.
- **Traffic and Transportation** – Solar receiver glare impacts that could be hazardous to motorists and pilots.
- **Visual Resources** – Glint or glare effects from high-profile solar receiver steam generators.

For **Cultural Resources**, **Traffic and Transportation**, and **Visual Resources** impacts, the Solar PV Alternative with its much lower vertical profile and reduced potential for operational glint and glare effects would offer the potential to develop mitigation measures that would go furthest toward reducing impacts on these resources.

If reducing or avoiding several direct and indirect environmental impacts and improving the effectiveness of mitigation measures are the critical factors, then the Solar PV Alternative with Single-Axis Tracking Technology would be environmentally superior to the proposed modified project.

For the Reduced Acreage Alternative with SPT Technology, staff identifies several impacts on **Biological Resources** that would be "much less than PSEGS," and staff considers this to be the primary benefit of this alternative compared to the proposed modified project. If lessening several impacts on biological resources is the critical factor, then the Reduced Acreage Alternative would be somewhat superior to the proposed modified project.

The subsection below, "Summary Conclusions for the Project Alternatives," provides further information on staff's conclusions.

CEQA REQUIREMENTS

As lead agency for the PSEGS, the California Energy Commission (Energy Commission) is required to consider and discuss alternatives to the proposed modified project. The guiding principles for the selection of alternatives for analysis in an environmental impact report (EIR) are provided by the California Environmental Quality Act Guidelines (State CEQA Guidelines) (Cal. Code Regs., tit. 14, § 15000 et seq.). Section 15126.6 of the State CEQA Guidelines indicates that the alternatives analysis must:

- describe a range of reasonable alternatives to the project, or to the location of the project, which would feasibly attain most of the basic objectives of the project;
- consider alternatives that would avoid or substantially lessen any significant environmental impacts of the proposed project, including alternatives that would be more costly or would otherwise impede the project's objectives; and
- evaluate the comparative merits of the alternatives.

These regulations also apply to the document used as a substitute for an EIR in a certified program (Cal. Code Regs., tit. 14, §§ 15251 and 15252).

The lead agency is responsible for selecting a range of project alternatives for examination and must publicly disclose its reasoning for selecting those alternatives (Cal. Code Regs., tit. 14, § 15126.6[a]). CEQA does not require an EIR to "consider every conceivable alternative to a project. Rather it must consider a reasonable range of potentially feasible alternatives…." The range of reasonable alternatives must be selected and discussed in a manner that fosters meaningful public participation and informed decision making (Cal. Code Regs., tit. 14, § 15126.6[f]). That is, the range of alternatives presented in this analysis is limited to ones that will inform a reasoned choice by Energy Commission decision makers. Under the "rule of reason," an EIR "need not consider an alternative whose effect cannot be reasonably ascertained and whose implementation is remote and speculative" (Cal. Code Regs., tit. 14, § 15126.6[f][3]).

The lead agency is also required to (1) evaluate a "no-project alternative," (2) identify alternatives that were initially considered but then rejected from further evaluation, and (3) identify the "environmentally superior alternative" (Cal. Code Regs., tit. 14, § 15126.6).

Alternatives may be eliminated from detailed consideration by the lead agency if they fail to meet most of the basic project objectives, are infeasible, or could not avoid any significant environmental effects (Cal. Code Regs., tit. 14, § 15126.6[c]).

ALTERNATIVES SCREENING AND PROJECT OBJECTIVES

The ideal process to select alternatives to include in the alternatives analysis begins with the establishment of project objectives. Section 15124 of the State CEQA Guidelines addresses the requirement for a statement of objectives (Cal. Code Regs., tit. 14, § 15124[b]):

> *A clearly written statement of objectives will help the lead agency develop a reasonable range of alternatives to evaluate in the EIR and will aid the decision makers in preparing findings or a statement of overriding considerations, if necessary. The statement of objectives should include the underlying purpose of the project.*

The underlying purpose of the PSEGS is to implement California's Renewables Portfolio Standard (RPS) program, which was established in 2002 under Senate Bill (SB) 1078, accelerated in 2006 under SB 107, and expanded in 2011 under SB X 1-2. Other related legislation has altered specific parts of the RPS program. The RPS program requires a retail seller of electricity to increase procurement from eligible renewable energy resources to 33 percent of total procurement by 2020. The California Public Utilities Commission (CPUC) and the Energy Commission are jointly responsible for implementing the program.

The importance of achieving these renewable energy goals was emphasized with the enactment of Assembly Bill (AB) 32, the California Global Warming Solutions Act of 2006, which sets aggressive greenhouse gas (GHG) reduction goals for the state.

The Renewable Energy Resources Program (SB 107) states that the Energy Commission's program objective is "to increase, in the near term, the quantity of California's electricity generated by in-state renewable electrical generation facilities, while protecting system reliability, fostering resource diversity, and obtaining the greatest environmental benefits for California residents" (Pub. Resources Code, § 25740.5[c]).

In February 2013, the project owner submitted a right-of-way (ROW) application and revised Plan of Development (POD) to the U.S. Bureau of Land Management (BLM) for the PSEGS. In July 2013, BLM published a draft supplemental environmental impact statement (SEIS) for the PSEGS (BLM 2013a). The PSEGS SEIS lists the project owner's objectives from the revised POD, starting with the owner's primary objective:

- Deliver 500 megawatts of renewable electrical energy to the regional electrical grid to fulfill its existing approved power purchase agreements (PPAs) for electrical sales from the facility.

These other project objectives address developing the PSEGS at a site that meets these criteria (BLM 2013a):

- Develop a solar thermal power plant at a site where some of the permits and other authorizations required for construction have been completed and/or obtained.
- Develop a site that is large enough to accommodate BrightSource Energy's Solar Power Tower technology.
- Develop a site that is in a BLM-designated Solar Energy Zone.
- Develop a site with an executed and approved Large Generator Interconnection Agreement for interconnection to a substation that would be operational in time to meet delivery of electricity under the approved PPAs.

Staff reviewed the project objectives from the Commission Decision for the licensed PSPP and assessed their applicability to the proposed modified project. Staff retained some of those original project objectives and incorporated other basic objectives that are consistent with the state's renewable energy goals:

- Safely and economically construct and operate a utility-scale solar energy project of up to 500 megawatts.
- Develop a renewable energy facility that will supply clean, renewable electricity, and assist Southern California Edison in satisfying its California Renewables Portfolio Standard program goals.
- Ensure construction and operation of a renewable electrical generation facility that will meet permitting requirements and comply with applicable laws, ordinances, regulations, and standards.
- Develop a renewable energy facility in a timely manner that will avoid or minimize significant environmental impacts to the greatest extent feasible.
- Develop a renewable energy facility in an area with high solar value and minimal slope.

Staff has given little consideration to the project owner's contractual obligations in this analysis of project alternatives. Also, staff's analysis broadens the alternatives analysis to allow full consideration of two renewable solar technologies other than BrightSource Energy's SPT technology. This approach is consistent with CEQA's purpose for an alternatives analysis. Staff briefly discusses some of the details from the project owner's objectives (e.g., the PPAs) in the subsections below addressing, “Potential Feasibility Issues,” for the alternatives.

RESPONSE TO COMMENTS

Comments were submitted by intervenors and others on the alternatives analysis for the proposed PSEGS. These comments are summarized, and staff’s responses are provided below.

STATE OF CALIFORNIA, ENERGY RESOURCES CONSERVATION AND DEVELOPMENT COMMISSION/CENTER FOR BIOLOGICAL DIVERSITY, LISA T. BELENKY, STATUS REPORT, TN # 70180, MARCH 29, 2013:

The Center for Biological Diversity (CBD) submitted comments on the preliminary staff assessment (PSA) stating that the alternatives proposed for analysis are inadequate and do not provide the needed range or address avoidance of all significant impacts (Center for Biological Diversity 2013). CBD commented that the alternatives analysis must look at alternative sites.

CEQA does not require that an alternatives analysis evaluate alternatives that would avoid *all* significant impacts of a proposed project. The State CEQA Guidelines requires an EIR to describe “a range of reasonable alternatives to the project, *or* to the location of the project, which would feasibly attain most of the basic objectives of the project but would avoid or substantially lessen *any* of the significant effects of the project, and evaluate the comparative merits of the alternatives” (Cal Code Regs., tit. 14, § 15126.6[a]) (emphasis added). This analysis evaluates project alternatives that could potentially reduce or avoid one or more of the environmental impacts of the proposed PSEGS.

In developing the alternatives analysis, staff reviewed the alternatives analysis from the Commission Decision on the original PSPP, including its analysis of several off-site alternatives. This approach is consistent with the State CEQA Guidelines requirements for an analysis of alternative locations, which states that limited new analysis is required “[w]here a previous document has sufficiently analyzed a range of reasonable alternative locations and environmental impacts for projects with the same basic purpose, the lead agency should review the previous document” (Cal Code Regs., tit. 14, § 15126.6[f][2][c]). As described above under, “Alternatives Considered in the Previous Analysis for the PSPP,” the Commission Decision concluded that the impacts of those alternatives would generally be similar to the impacts of Reconfigured Alternative #2 or #3. No off-site alternative evaluated under the PSPP was determined to be feasible.

CEQA does not establish a requirement for the number of alternatives to be evaluated. The proposed PSEGS is on a site that is approved for development of a utility-scale solar energy project, and as described in BLM's draft SEIS, it is the subject of the ROW application submitted by the project owner for the PSEGS. Given these facts, it is unlikely that any alternative site would be found to be potentially feasible (i.e., capable of being accomplished in a successful manner within a reasonable period of time). The work required to obtain site control and complete the required environmental clearances to allow development to proceed would likely render such an alternative infeasible. Staff's alternatives analysis includes a detailed analysis of on-site alternatives that could feasibly attain most of the basic objectives of the project.

CBD commented on the large-scale industrial areas in many parts of southern and central California that could be converted to solar centers and thus should be considered an alternative to the proposed PSEGS. CBD commented that the alternatives analysis should explore use of distributed generation solar energy production as well as efficiency upgrades and conservation.

Staff observes that no alternative sites are identified that could be considered potentially feasible alternatives to the proposed PSEGS. The range of alternatives required in an EIR is governed by the "rule of reason," meaning that an EIR need only set forth those alternatives necessary to permit a reasoned choice. Under the "rule of reason," an EIR "need not consider an alternative whose effect cannot be reasonably ascertained and whose implementation is remote and speculative" (Cal. Code Regs., tit. 14, § 15126.6[f][3]). Discussions are provided below on staff's review of potential off-site alternatives. Please see the discussions under the subsections, "Alternatives Considered in the Previous Analysis for the PSPP," and "Alternatives Considered But Eliminated from Detailed Consideration for the Proposed PSEGS."

Distributed generation and energy efficiency are discussed in detail below.

STATE OF CALIFORNIA, ENERGY RESOURCES CONSERVATION AND DEVELOPMENT COMMISSION/BASIN AND RANGE WATCH, LAURA CUNNINGHAM AND KEVIN EMMERICH, COMMENTS ON THE PSA, TN # 200078, JULY 28, 2013:

Basin and Range Watch submitted comments on the PSA stating that the PSEGS alternatives analysis should consider a brownfield site alternative[2], a Westland Solar Park alternative, and a distributed generation alternative (Basin and Range Watch 2013).

[2] The term, "brownfield site," generally refers to a piece of industrial or commercial property that is abandoned or underused and often environmentally contaminated.

Similar to staff's response to CBD's comments, no alternative brownfield site is identified that could be analyzed as a potentially feasible alternative to the proposed PSEGS. If a specific brownfield site was identified that could accommodate a utility-scale renewable solar project such as PSEGS, an environmental analysis of the site would be necessary to determine the comparative environmental effects of such an alternative. Because no site is identified, no such analysis is possible.

Westlands Solar Park is a combined public and private effort to master plan renewable development and infrastructure for large scale solar projects on approximately 24,000 acres of disturbed land in Westlands Water District, which is located in Fresno and Kings counties on the west side of the San Joaquin Valley. Regional developed uses near Westlands Solar Park include rural residential areas and several small- to medium-size communities within approximately 5 miles to 10 miles of the site. The Westlands Solar Park has initial planning estimates for development of phased projects totaling up to approximately 2,400 MWs of solar arrays by 2025. As stated in the State CEQA Guidelines, among the factors that may be taken into account when addressing the feasibility of alternatives is "whether the proponent can reasonably acquire, control, or otherwise have access to the alternative site…" (Cal. Code Regs., tit. 14, § 15126.6[f][1]). The PSEGS project owner does not own or otherwise have development rights to lands at Westlands Solar Park. Also, construction and operation of a solar power plant with SPT technology at Westlands Solar Park would be completely inconsistent with the planned intent to develop the area with much lower profile solar PV arrays. Development of any type of solar energy project by the PSEGS project owner at Westlands Solar Park is extremely speculative, and it is not evaluated further in this staff assessment.

Basin and Range Watch also requested inclusion of a No-Project Alternative. For PSEGS, the No-Project Alternative evaluates the impacts of the proposed modified project compared to the impacts of constructing and operating either of the approved alternatives from the original PSPP. In this instance, the No-Project Alternative does not mean that existing conditions would persist at the site absent the proposed modified project. Please see the discussion below under "No-Project Alternative."

The distributed generation category of renewable energy is discussed below.

COLORADO RIVER INDIAN TRIBES, WAYNE PATCH SR., COMMENTS ON THE PSA, TN # 200075, JULY 29, 2013:

Colorado River Indian Tribes submitted comments on the PSA objecting to the absence of a review of project alternatives (Colorado River Indian Tribes 2013). Staff acknowledges that the PSA did not include an analysis of alternatives. To correct the lack of an alternatives analysis in the PSA, this final staff assessment evaluates a reasonable range of potentially feasible alternatives to the proposed PSEGS, in accordance with CEQA.

ALTERNATIVES CONSIDERED IN THE PREVIOUS ANALYSIS FOR THE PSPP

REVIEW OF ALTERNATIVE PROJECT CONFIGURATIONS FOR THE PSPP

In response to scoping comments on the original PSPP, the project site was reconfigured to avoid the northern third of the site (Energy Commission 2010a). This Reconfigured Alternative separated Unit 1 of the proposed PSPP into two polygons. Unit 2 would have been retained at approximately the same location with an altered site boundary. The total project site acreage would have increased by approximately 180 acres. The Commission Decision concluded that the significant impacts from this Reconfigured Alternative would have been nearly the same as those identified for the proposed PSPP, and it was not approved by the Energy Commission.

The original PSPP alternatives analysis evaluated a smaller parabolic trough project with a net generating electrical capacity of 375 megawatts (MWs). The original Reduced Acreage Alternative would have required approximately 25 percent less acreage compared to the original PSPP. This alternative would have altered the site boundaries for Units 1 and 2 to avoid sand dune habitat, Mojave fringe-toed lizard habitat, and designated Desert Tortoise Critical Habitat. The Commission Decision concluded that the original Reduced Acreage Alternative would reduce, but not eliminate, immitigable impacts on land use and visual resources. The conversion of desert lands and open space at the site and impacts on cultural resources were determined to be cumulatively considerable impacts of this alternative. The Commission Decision concluded that Reconfigured Alternative #2 or #3, with implementation of mitigation measures, would have effects that would be similar to the original Reduced Acreage Alternative while retaining the PSPP’s full electrical capacity of 500 MWs. The original Reduced Acreage Alternative was not approved by the Energy Commission.

REVIEW OF OFF-SITE ALTERNATIVES FOR THE PSPP

<u>North of Desert Center Alternative</u>

Scoping comments on the original PSPP requested consideration of an alternative site on disturbed, private lands. In response to those comments, staff included an alternative at the North of Desert Center site for full analysis and comparison to the PSPP (Energy Commission 2010b). The preliminary study area for this alternative covered approximately 5,800 acres; approximately 37 landowners own property at the alternative site. Of the total acreage, approximately 873 acres are under federal ownership and are probably managed by BLM. Most of the remaining site is under private ownership. It was determined that this alternative would require an approximately 4.6-mile-long transmission line that would follow an existing Southern California Edison (SCE) 161-kilovolt (kV) transmission line that crosses the site.

Surrounding land uses include the small community of Desert Center, which is a little over 2 miles from the site. The small resort community of Lake Tamarisk is less than 1 mile from the site. Segments of Desert Center Rice Road (State Route 177) cross the site; sparse rural development is located along this route.

Staff concluded that construction and operation of a 500-MW parabolic trough project at the North of Desert Center site would reduce impacts on biological resources primarily because most of the study area was fallow agricultural land with lower biological value overall compared to the original PSPP site. Staff concluded that impacts on visual resources impacts would be similar to the PSPP. Cultural resources staff determined that construction and operation of a parabolic trough project at the North of Desert Center site would reduce impacts on cultural resources compared to the PSPP although a complete archaeological and built-environment survey would be required to verify preliminary conclusions for those resources. Desert Center Airport is a small, private-use airport near the east side of the alternative site. Chuckwalla Valley Raceway is a public-use raceway at the Desert Center Airport. The previous alternatives analysis identified a potentially significant impact from constructing and operating a renewable solar power plant adjacent to the Desert Center Airport. The impact of converting agricultural land at the alternative site to a non-agricultural use could have required mitigation to reduce the impact to less than significant.

The Commission Decision for the original PSPP proceeding concluded that the North of Desert Center off-site alternative would have impacts similar to the proposed PSPP (Energy Commission 2010a). The Commission Decision also concluded that negotiations to acquire many privately-owned properties for this alternative would have delayed the PSPP to an extent that would have rendered it uneconomical (or infeasible).

Off-Site Alternatives That Were Not Evaluated in Detail for the PSPP

The staff assessment for the original PSPP reviewed these other potential off-site alternatives:

- Cibola Alternative
- Palen Pass Alternative
- Desert Center Alternative
- Palo Verde Alternative

These other off-site alternatives were not evaluated in detail because they failed to meet most of the project objectives or would not have reduced or avoided the significant impacts of the original PSPP.

ALTERNATIVES CONSIDERED BUT ELIMINATED FROM DETAILED CONSIDERATION FOR THE PROPOSED PSEGS

Staff evaluated a 500-MW SPT with Lower Tower Height Alternative and an SPT with Energy Storage Alternative and determined that the impacts of the proposed modified project would not be reduced or avoided with construction and operation of these alternatives at the PSEGS site. Overviews of these two alternatives are provided below. Staff researched and analyzed the potential for the *distributed generation* category of renewable energy production to be a potentially feasible alternative to the proposed project; the analysis and related conclusions are provided below. *Energy efficiency* strategies are critical to reducing energy consumption in the state. A discussion of energy efficiency is provided below to acknowledge the importance of achieving all cost-effective energy efficiency for the state. No potentially feasible off-site alternatives are identified that could reduce or avoid the significant impacts of the PSEGS.

SPT with Lower Tower Height Alternative

Overview

Staff evaluated an alternative that could resemble the Ivanpah Solar Electric Generating System (ISEGS), which is under construction near the Nevada state border in San Bernardino County. ISEGS includes three 460-foot-tall metal power towers (Ivanpah 1, 2, and 3) surrounded by three solar fields of heliostats. The total acreage of the ISEGS solar fields is approximately 3,238 acres, and the three projects have a total electrical capacity of 370 MWs. Compared to ISEGS, the proposed PSEGS would include two 750-foot-tall solar power towers in two heliostat fields that would cover approximately 3,576 acres and have an electrical capacity of 500 MWs. Land use efficiency would be reduced under this alternative. In other words, the SPT with Lower Tower Height Alternative would require more acres per MW of capacity. Staff estimates that the total electrical capacity of this alternative could be somewhat less than PSEGS.

Staff considered whether the lower tower height of this alternative would reduce or avoid impacts on biological resources, and avian species in particular; visual resources; and cultural resources. For these and the other environmental resources analyzed in this staff assessment, staff estimates that impacts would generally be the same or similar to the proposed PSEGS.

Decision to Eliminate the SPT with Lower Tower Height Alternative from Detailed Consideration

Biological Resources

The SPT with Lower Tower Height Alternative would not avoid or substantially reduce impacts on biological resources. Terrestrial impacts and all other biological resources impacts would be similar to the proposed modified project, with the exception of impacts on avian species. Power tower technology concentrates solar flux in the airspace over the heliostat field. Concentrated solar flux has the potential to blind, kill, or injure any flighted species that is exposed. The severity of injury depends on the duration of exposure as well as the intensity of the flux. With a 460-foot-tall power tower, staff expects that the location of the flux field would be lowered, roughly commensurate with the tower height. With the 750-foot power tower of the proposed PSEGS, the portion of the flux field considered to be dangerous (over 5 kilowatts per square meter) occupies a volume around each power tower, starting around 300 feet in elevation (Rio Mesa Solar I and II, LLCs 2012a). With a 460-foot power tower, the flux field would also be lower, but staff assumes the field to occupy the same approximate volume of airspace.

Depending on the elevation of the flux field, different suites of species would likely be impacted. A lower tower could reduce impacts on migrating birds, but would potentially have greater impacts on avian and bat species present year-round. Resident species of birds, such as meadowlark (*Sturnella neglecta*), a ground-feeding bird, could have a higher potential to enter an airspace containing concentrated flux. Little data is available on at-risk species, and therefore a more robust, empirical analysis is not possible. However, significant reductions in risk of injury or death due to flux exposure would not be a reasonable conclusion for an SPT alternative with a lower power tower height.

Another adverse impact associated with SPT technology is the risk of avian collision with project features, generation-tie lines, and heliostats. The reflective surfaces of heliostats, when viewed from a distance, may create the appearance of water; smooth surfaces, such as glass PV panels or heliostat mirrors, may polarize light. Both of these unintentional consequences are suspected to attract birds to a site where they may collide with heliostat surfaces (or the surfaces of other solar collectors) and either suffer instant mortality, or likely succumb to injuries shortly thereafter. A lower power tower would not eliminate this potential risk of attraction of avian, bat, and insect species. Further descriptions and analysis of potential impacts on avian species (e.g., risk of collision with project features) are provided below for each of the project alternatives; see the “Biological Resources” subsections under, “Alternatives Evaluated in Detail.”

Cultural Resources

Construction and operation of the SPT with Lower Tower Height Alternative would not substantively alter the primary significant impacts of the proposed modified project on cultural resources, namely the profound visual intrusion of the proposed PSEGS two, 750-foot power towers across a significant portion of western Chuckwalla Valley. The physical destruction of the relatively modest set of archaeological deposits and built-environment ruins on the facility site, while technically significant under the licensed PSPP, is of secondary significance relative to the visual impacts of the proposed PSEGS throughout the broader valley. The reduction of the SPT height from approximately 750 feet to approximately 460 feet would not greatly reduce the stark visual impact of the towers’ bright solar receiver steam generators (SRSGs) on cultural resources. Therefore, the impact of this alternative on cultural resources would be similar to the visual impact of the proposed PSEGS. No impacts on cultural resources would be reduced or avoided under the SPT with Lower Tower Height Alternative.

Visual Resources

As described in the **VISUAL RESOURCES** section of this staff assessment, the proposed PSEGS site is located on a broad, flat, desert plain that is bordered by rugged mountain ranges. The area of potential visual effect (i.e., the visual sphere of influence [VSOI]) is extensive and encompasses much of the Chuckwalla Valley and the site-facing slopes and ridgelines of the surrounding mountains. Staff concludes that the extreme glare from the proposed modified project's two solar receivers would be seen from the Chuckwalla Mountains Wilderness and Palen McCoy Wilderness at distances of as little as 4½ miles. Staff concludes that the proposed PSEGS would be highly prominent in views from sensitive viewing locations and that no feasible mitigation measures would reduce visual resources impacts to less-than-significant levels.

Given the level terrain of the Chuckwalla Valley and the high visibility of the site from the surrounding mountain ranges, staff concludes that the SPT with Lower Tower Height Alternative would not reduce the project's VSOI to any great extent. Because land use efficiency for this alternative would be somewhat lower than PSEGS, the total area covered by a single solar field of heliostats would be greater for an alternative with a lower power tower. For near to far middleground views, the bright solar reflection off the heliostat mirrors from the horizontal plane could affect a somewhat larger area compared to the proposed PSEGS. However, in general, visual resources impacts from the disruptive effects of glint and glare would be similar to the proposed modified project, and no visual resources impacts would be reduced or avoided under this alternative.

SPT with Energy Storage Alternative

Overview

An SPT with Energy Storage Alternative would combine solar thermal technology with added molten-salt storage at the site. Thermal energy storage (TES) allows solar energy to be captured during the day and retained in a liquid salt heat transfer fluid. Liquid salt has inherent TES properties. In its liquid state, salt has a viscosity similar to water. Salt remains in a liquid state at very high temperatures whereas water turns to steam. A fossil fuel source (either liquefied petroleum gas [propane] or compressed natural gas) is required prior to plant start-up for the initial melting, heating, and conditioning of the salt thermal storage medium. No other fossil fuel supply is required for plant operations.

An SPT with energy storage power plant requires heliostats to concentrate the sun's rays on the water-filled solar boiler at the top of the central receiver tower in each solar field. The resulting high-temperature, pressurized steam is piped through a conventional steam turbine generator to produce electricity. To store the heat, some of the steam produced during the day is used to superheat molten salts held in a tank. The heat retained in the molten salts is available to convert water to steam, which is used to run the plant's steam turbine generators to produce electricity during solar transients (e.g., cloud cover), and during early evening and early morning hours.

This technology offers some additional stability and flexibility of generator operation inherent with liquid salt solar systems that is similar to that associated with the proposed PSEGS' supplemental natural gas firing. Because this technology uses liquid salt, a medium that can be heated to a very high temperature, the steam cycle is efficient. Because the liquid salt can be stored with very little heat loss, this system allows power to be generated on demand during the day or night regardless of short-term weather fluctuations.

Solar thermal technologies with energy storage can store excess energy when on-line generation exceeds load (Energy Commission 2011a). Adding thermal storage to a concentrating solar power plant can result in generation of dispatchable electricity depending on daily resource constraints.

To accomplish the approximate electrical capacity of 500 MWs of the proposed PSEGS, adding energy storage components would likely require a larger power plant site. Additional acreage would be needed to accommodate the molten-salt storage tanks, and additional heliostats would be required to generate heat for the thermal storage component. BrightSource Energy has stated that adding thermal storage requires the addition of at least 18 percent more heliostats to the solar field (Rio Mesa Solar I, II, and III, LLCs 2012b).

Rice Solar Energy Project (RSEP) is a 150-MW SPT project that was approved for construction and operation by the Energy Commission in December 2010. SolarReserve will develop RSEP on approximately 1,500 acres of private land in the Colorado Desert in eastern Riverside County. Full site mobilization and the start of construction are planned for March 2014.

SolarReserve's projects include a central receiver tower surrounded by heliostats. Instead of super heating water in the solar boiler at the top of the tower, the sun's rays directly heat molten salt that can be stored to generate electricity late at night. The technology used by SolarReserve allows large quantities of thermal energy to be captured and retained for several days and extracted on demand (Energy Commission 2010c). SolarReserve expects RSEP to generate stable, predictable, and controllable electricity.

Decision to Eliminate the SPT with Energy Storage Alternative from Detailed Consideration

Staff's alternatives analysis for the Hidden Hills Solar Electric Generating System (HHSEGS) included detailed environmental analyses of an SPT alternative with added molten-salt storage. The HHSEGS was proposed to use BrightSource Energy's SPT technology, and of the project alternatives evaluated for the HHSEGS, the SPT with Energy Storage Alternative was most similar to the HHSEGS. For most environmental resources, comparative impacts for the SPT with Energy Storage Alternative were determined to be similar to the HHSEGS project (Energy Commission 2012a). For impacts that would correlate to the extent of the HHSEGS site footprint, potentially greater impacts were identified for this alternative because of the possible need to expand the site boundary for the molten-salt storage tanks and additional heliostats. Staff concluded that potential impacts on groundwater resources could increase proportionally with increased water usage under the energy storage alternative, and that impacts relating to groundwater depletion would be somewhat greater than HHSEGS. Staff concluded that impacts on many plant and wildlife species would either be similar to or somewhat greater than the HHSEGS.

The PSEGS is proposed to use the same technology as the previously evaluated HHSEGS; therefore, this alternative is also most similar to the proposed PSEGS. Staff concluded that no significant impact identified for the HHSEGS would be avoided or substantially lessened under the SPT with Energy Storage Alternative. Staff assumes that a comparative analysis of the impacts of the proposed PSEGS to this alternative would reach the same or very similar conclusions as those in the HHSEGS alternatives analysis. For this reason, the SPT with Energy Storage Alternative has been eliminated from detailed consideration in this alternatives analysis.

Off-Site Alternatives

Overview

As described above, several off-site alternatives were evaluated in the previous analysis for the PSPP, including the North of Desert Center Alternative. Use of this alternative site to construct a 500-MW SPT power plant similar to the proposed modified project could potentially cause impacts on visual resources that would be much greater than the PSEGS. Impacts on local residents, the Desert Center Airport, and recreational visitors to the Chuckwalla Valley Raceway from the effects of glint and glare would be significant. Impacts on avian species would be similar to the proposed PSEGS. Construction and operation of a renewable solar power plant using SPT technology at the North of Desert Center Alternative site would probably have impacts similar to or somewhat greater than the proposed PSEGS. Although it is unknown how many residences may be located at the North of Desert Center Alternative site, staff presumes that displacement of residents could be an impact of a utility-scale solar project at this site.

The vertical scale of the proposed PSEGS with its two SPTs topped by the SRSGs would be much greater compared to the parabolic trough technology for the previously approved project. In theory, if a new, potential off-site alternative was identified, construction of a utility-scale solar energy project using SPT technology would be highly unlikely to reduce environmental impacts on visual resources, cultural resources, or biological resources. Any off-site alternative at a disturbed site is likely to be closer to developed areas, and potential impacts on local residents and adjacent developed uses from construction and operation of the PSEGS at such a site would be greater compared to the approved sites for the PSPP (i.e., Reconfigured Alternatives #2 and #3). Potential impacts on avian species could be similar to the PSEGS regardless of the site location. Site specific analyses would be needed to reach conclusions for comparative impacts on cultural resources and terrestrial wildlife species and sensitive habitats. None of the off-site alternatives from the previous analysis were determined overall to reduce or avoid impacts of the PSPP. For a project using SPT technology, it is unlikely that a different off-site alternative would cause lesser impacts on critical environmental resources. It is improbable that an off-site alternative could be identified where it would be feasible to achieve site control and use within a reasonable time frame.

In July 2012, BLM and the U.S. Department of Energy (DOE) published the *Final Programmatic Environmental Impact Statement (PEIS) for Solar Energy Development in Six Southwestern States* (BLM and DOE 2012). The Record of Decision (ROD) for the Solar PEIS was issued a few months later. The Riverside East Solar Energy Zone (SEZ) is one of the extensive regions encompassing public lands in the southwestern states that was subject to environmental review and determined to be appropriate for development of renewable energy projects with implementation of design features to reduce the environmental impacts of those projects. The PSEGS site is in the Riverside East SEZ, and most of the PSEGS site appears to be in an area delineated as "developable" (BLM and DOE 2012).

The Desert Renewable Energy Conservation Plan (DRECP) is a multiagency conservation and planning document intended to guide solar and other renewable energy project siting in the Mojave and Colorado/Sonoran deserts of California, and provide for the conservation and management of certain species, habitats and natural communities that may be affected by those projects. The state and federal agencies that are developing the DRECP are collectively called the Renewable Energy Action Team (REAT) agencies. The Draft Preliminary Conservation Strategy (Draft PCS) is a key part of the DRECP that was published by the REAT agencies in October 2011 (Energy Commission 2011b). The Draft PCS identified preliminary renewable energy study areas (RESAs) based on the presence of available renewable energy resources and a lower potential for conflicts with conservation goals. The preliminary conservation strategy map of the RESAs includes approximately 382,390 acres in east Riverside County near Blythe. The Blythe RESA encompasses an area around Interstate 10 (I-10) that overlaps extensively with the Riverside East SEZ.

The REAT agencies are developing the DRECP alternatives for consideration in the Draft DRECP, which is planned for publication in 2013. In a January 2013 publication on the *Description and Comparative Evaluation of Draft DRECP Alternatives*, four of the preliminary DRECP alternatives were noted to retain the entire Riverside East SEZ as a *development focus area* (DFA) under the DRECP (REAT 2013). The other three were noted to retain portions of the Riverside East SEZ as a DFA. Staff observes that the alternatives analyzed in the forthcoming Draft DRECP, including the preferred alternative, may be different than the preliminary DRECP alternatives presented in the January 2013 REAT publication (REAT 2013). The DRECP will ultimately only cover and provide permit streamlining for renewable energy generation projects inside DFAs. Although the PSPP site is approved for a utility-scale solar energy project, the extent of the DFA in the project area and its relationship to the PSPP site is undetermined.

Conclusion for Off-Site Project Locations

The PSEGS site was licensed by the Energy Commission in 2010 for construction and operation of either Reconfigured Alternative #2 or #3. The Commission Decision for the PSPP concluded that no off-site alternative would present a feasible alternative to the licensed site, and the environmental analyses resulted in conclusions that impacts of the off-site alternatives would generally be similar to the PSPP evaluated in 2009–2010. The PSEGS site is within the Riverside East SEZ, which indicates at least its potential suitability for development of a renewable energy facility. No off-site location is identified that would avoid or substantially lessen any of the significant effects of the proposed modified project. No feasible alternative locations are identified for the proposed PSEGS where site control and use could be obtained in a reasonable time frame.

Distributed Generation

Overview

Governor Jerry Brown's Clean Energy Jobs Plan identifies a goal of installing 20,000 MWs of new renewable capacity by 2020, including 12,000 MWs of localized electricity generation close to consumer loads and transmission and distribution lines (i.e., distributed generation [DG])[3] (Energy Commission 2011a). These targeted renewable capacity goals support California's RPS program goals. In 2010, the state had more than 10,000 MWs of installed renewable capacity that provided nearly 16 percent of total retail sales of electricity. Of that amount, about 3,000 MWs represents DG, and there is an additional estimated 6,000 MWs of DG either under development or authorized under existing programs (Energy Commission 2011a and 2013).

Distributed solar facilities vary in size from kilowatts to tens of megawatts and do not require transmission to get to the areas where the electricity is used. Renewable DG technologies like small PV can be located in industrial areas on previously disturbed land or on existing residential, industrial, or commercial buildings. Standards, codes, and fees vary widely for DG projects, and land use requirements for identical systems can vary significantly from jurisdiction to jurisdiction. Efforts at the national, state, and local levels are underway to identify and provide solutions to barriers to permitting renewable DG facilities (Energy Commission 2011a).

2012 Integrated Energy Policy Report

The *2012 Integrated Energy Policy Report (IEPR) Update* was adopted by the Energy Commission in February 2013. The main element of the 2012 IEPR Update is the Energy Commission's Renewable Action Plan with five overarching strategies (Energy Commission 2011a and 2013):

- *Strategy 1* – Identify and prioritize geographic areas for renewable utility-scale and DG development.

[3] The total 20,000 MWs from the Governor's Clean Energy Jobs Plan includes 8,000 MWs of utility-scale renewable capacity from wind, solar, and geothermal projects.

- *Strategy 2* – Evaluate costs and benefits of renewable projects.
- *Strategy 3* – Minimize interconnection costs and time at the transmission and distribution levels.
- *Strategy 4* – Promote incentives for projects that create in-state jobs and economic benefits.
- *Strategy 5* – Promote and coordinate existing financing and incentive programs for critical stages in the renewable development continuum.

A comprehensive set of recommended actions relating to each strategy was developed based on discussions at public workshops and comments submitted by community stakeholders, industry representatives, and state and local agency participants. A few of the strategies and recommended actions are discussed here.

Recommendations for Strategy 1 include incorporating DG energy development zones into utility distribution system investment plans and local planning processes (Energy Commission 2013). The aim is to develop a process that can be replicated by local jurisdictions in the state to analyze the suitability of areas for DG and place priority on developing those areas. Where possible, the DG zones should be targeted to areas where system upgrades and modernization are anticipated, which could allow for increased penetration of DG resources. Actions and implementation steps include a directive for the Energy Commission and CPUC to work with each IOU to establish pilot working groups to (1) create maps identifying DG renewable energy development zones, and (2) demonstrate how improved coordination between utility infrastructure planning can build markets that better support high penetrations of renewable DG.

A separate but related recommendation requires coordination with local governments to identify renewable energy development zones as preferred areas for all sizes and technology types of renewable energy projects. Actions and implementation steps include a directive for the Energy Commission to coordinate with utilities and interested local jurisdictions to create and identify renewable energy development zone overlay maps to include in comprehensive land use and infrastructure plans.

Another recommendation for Strategy 1 is to continue developing renewable energy on government property, including renewable DG. A barrier to installing renewable DG on state properties relates to the financing of state buildings with lease revenue bonds, which requires notification and approval of the bond owners before development of the property can proceed. To overcome this barrier, an action step is identified for the Department of General Services, Department of Finance, and State Treasurer's Office to jointly develop a standardized method to expedite renewable DG installations on properties financed with state revenue bonds.

Challenges for Strategy 3 identify a lack of comprehensive distribution system planning, which is expected to result in interconnection delays, lost opportunities to deploy DG strategically, and increased costs. Recommendations for distribution interconnection include several action steps for the Energy Commission, CPUC, California Independent System Operator (CAISO), local governments, environmental groups, and utilities to take to build transparency into distribution planning. The goal is to develop a modern and smart distribution network that can actively accommodate high levels of DG.

Distributed Generation Programs

CPUC oversees two incentive programs for customer-side of the meter DG (also called *on-site generation* or *self generation*) for customers in the territories of Pacific Gas & Electric Company (PG&E), San Diego Gas & Electric (SDG&E), and SCE (CPUC 2013). The customer-side DG programs include several existing, new, and emerging distributed energy sources, including solar electric. The Energy Commission oversees related incentive programs.

The programs supporting on-site solar projects include CPUC's California Solar Initiative, the Energy Commission's New Solar Homes Partnership, and a variety of solar programs offered through publicly owned utilities. The overall goal of these programs, known collectively as Go Solar California, is to encourage Californians to install 3,000 MWs of solar energy systems on homes and businesses by 2016 (CPUC 2013). Generation from these facilities may or may not be able to produce excess electricity exported to the distribution or transmission system, but all are connected to the electric grid (Energy Commission 2011a).

CPUC has implemented policies and programs related to procurement of utility-side DG (also called *wholesale* or *system-side generation*) (CPUC 2013). Under its investor-owned utility (IOU) solar PV programs, CPUC authorized PG&E, SDG&E, and SCE to own and operate PV facilities and to execute solar PV PPAs with independent power producers through a competitive solicitation process. Based on decisions issued by CPUC in 2009 and 2010, these programs will yield up to 1,100 MWs of new solar PV capacity in the next few years. The energy produced under the solar PV programs will contribute to meeting the state's RPS program goals.

CPUC provides incentives for the development of DG through its Self-Generation Incentive Program (SGIP) (CPUC 2013). This program provides financial incentives for installing new, qualifying, self-generation equipment that meets all or a portion of the electric energy needs of a facility. SGIP administrators include PG&E, SCE, Southern California Gas Company, and the California Center for Sustainable Energy. Eligible fuels for eligible SGIP generating technologies include several renewable and non-renewable fuels. In 2009, SB 412 modified SGIP to require identification of distributed energy resources that will contribute to GHG reduction goals.

CPUC's Renewable Auction Mechanism (RAM) was created for the procurement of renewable DG projects generating from 3 MWs up to 20 MWs of electricity. RAM is open to all renewables (e.g., solar PV, small hydro, biogas, wind, and geothermal). CPUC adopted RAM in 2010 to encourage development of resources that can use existing transmission and distribution infrastructure and contribute to the state's RPS program in the near term. CPUC initially authorized the large IOUs to procure 1,000 MWs through RAM by holding four competitive auctions over 2 years. Total procurement was expanded in early 2012 to 1,299 MWs. Project eligibility and viability is determined by the IOUs based on the offerer's ability to demonstrate the following:

- *Site Control* – 100 percent site control obtained through direct ownership, lease, or an option to lease or purchase that may be exercised when the RAM contract is awarded.
- *Development Experience* – One member of the development team has completed at least one project of similar technology and capacity or has begun construction of at least one other similar project.
- *Commercialized Technology* – The project is based on a commercialized technology.
- *Interconnection Application* – An interconnection application has been filed.

The first two RAM auctions resulted in approval of 30 renewable DG contracts for a total of 400 MWs of electricity. Of those totals, 28 projects totaling 370 MWs are online or on schedule (CPUC 2013). The third RAM auction closed at the end of December 2012. The IOUs executed 21 contracts for 337 MWs; of those that received CPUC's approval in May 2013, 17 contracts are on schedule for a total of 258 MWs. Most of the contracts are for solar PV projects. The fourth RAM auction closed at the end of June 2013.

Under three recent CPUC decisions in 2012 and 2013, CPUC granted, in part, SCE's and SDG&E's respective petitions for modification to merge each utility's solar PV programs into the RAM program. SCE's program targeted small rooftop projects (1–2 MWs), and SDG&E's program targeted small ground-mount projects (1–5 MWs). By merging the utility solar programs into RAM, CPUC is attempting to minimize ratepayer expenditures on renewable DG and provide a more efficient DG procurement process.

The 2012 IEPR Update addresses recommendations to minimize overall risks and maximize the value of the renewable portfolios, including a suggested action item for CPUC to evaluate RAM projects and assess the costs and benefits of siting those projects. For example, the CPUC should identify whether projects would be located in areas identified by utilities as having low costs for transmission and distribution. The 2012 IEPR Update recommends that CPUC consider changes to the RAM selection criteria based on the cost and benefit data findings (Energy Commission 2013).

Decision to Eliminate Renewable Energy Distributed Generation from Detailed Consideration as an Alternative to the PSEGS

Comments received during the proceedings for other siting cases for large-scale renewable energy projects have stated that the alternatives analyses for such central station projects must include the distributed generation photovoltaic (DGPV) category of renewable energy generation. Both *concentrated* and *distributed* types of systems result in production of electricity from renewable sources (i.e., both use solar technologies). However, the characteristics of the DG category of renewable energy generation make it an impracticable alternative in the context of a CEQA alternatives analysis. In no instance has a potential site for a DGPV alternative been proposed.

As discussed above, CEQA does not require consideration of “every conceivable alternative to a project…” (Cal Code Regs., tit. 14, § 15126.6[a]). CEQA does not require consideration of “an alternative whose effect cannot be reasonably ascertained and whose implementation is remote and speculative” (Cal Code Regs., tit. 14, § 15126.6[f][3]). Staff concludes that a DGPV alternative is unlikely to provide a feasible alternative to the proposed modified project for the reasons discussed below:

- *Lack of Defined Projects with Sites* – Compared to a large project such as the PSEGS that is proposed for construction on a defined site, a *renewable DG alternative* is amorphous and impossible to analyze. Some renewable DG projects are carried out by proponents and agencies at defined sites; however, the existence of renewable DG projects does not mean that a DG alternative as a category of renewable energy generation could be a valid alternative to a larger generation project such as the PSEGS. Achieving a level of electrical generation comparable to the proposed PSEGS would require putting together many small-scale (approximately 1–5 MWs each) sites that could, in theory, include rooftop and ground-mount PV systems. Even if such sites could be identified, it is unreasonable to assume the PSEGS project owner could obtain access to and use of multiple small sites that are owned and controlled by other people or organizations. As discussed below, participation in on-site generation programs is voluntary. The feasibility of a renewable DG alternative is extremely speculative.
- *Voluntary Participation in On-site Generation Programs* – Participation in the state’s on-site generation incentive programs (described above) is based on decisions made by individual residents and property and business owners. Participation in the incentive programs is elective; no laws or regulations mandate installation of on-site renewable energy systems; and utilities do not approve or deny DG systems on private property. Although the importance of the state’s DG incentive programs cannot be overstated, it is not possible to treat a conglomeration of DGPV (or other types of DG) projects as a potentially feasible alternative to a utility-scale renewable energy project such as the proposed modified project.
- *Failure to Meet Critical Project Objectives* – The basic project objectives for the PSEGS include developing a renewable energy facility that will contribute to meeting the state’s RPS program goals. Based on electricity supply and demand forecast reports prepared by Energy Commission staff, as well as expert witness testimony in prior proceedings (e.g., the HHSEGS and the ISEGS siting cases), renewable DG projects alone would not supply enough electricity to meet the state’s mandated RPS program goals. Achieving the RPS program goals requires energy generation from a mix of renewable sources, and not merely one to the exclusion of others. Various agency publications identify the need to increase renewable generating capacity from DG and utility-scale sources; both are essential to successfully meeting RPS program goals. Therefore, rejection of the proposed PSEGS on the grounds that some renewable DG projects will be built would be inconsistent with the state’s RPS program objectives. Such a decision would also be inconsistent with the PSEGS goals of helping to meet such objectives.

Energy Efficiency

In 2003, the principal energy agencies in the state jointly created and adopted the *Energy Action Plan* (EAP), which identifies goals and actions to eliminate energy outages and excessive price spikes in electricity and natural gas (Energy Commission and CPUC 2003). The EAP states the importance of having reasonably priced and environmentally sensitive energy resources to support economic growth and attract new investments that will provide jobs and prosperity for California consumers and taxpayers. The EAP envisions a "loading order" of energy resources to guide agency decisions: (1) the agencies will optimize all strategies for increasing conservation and energy efficiency to minimize increases in electricity and natural gas demand, (2) recognizing that new generation is necessary and desirable, the agencies intend to meet the need first by renewable energy resources and distributed generation, and (3) because the preferred resources require both sufficient investment and adequate time to "get to scale," the agencies will support additional clean, fossil-fueled, central station generation (Energy Commission and CPUC 2003). Section 454.5(b) of the California Public Utilities Code addresses requirements for an electrical corporation's proposed procurement plan, including the requirement to "first meet its unmet resource needs through all available energy efficiency and demand reduction resources that are cost effective, reliable, and feasible."

In 2008, an update to the EAP was published that examines the state's ongoing actions in the context of global climate change following passage of AB 32. The updated EAP iterates how the EAP represents a collaborative process that is subject to change and updating over time. The EAP does not supersede or replace the extensive efforts of the Energy Commission's IEPR, which remains the overall guiding document on energy policy. The IEPR addresses a wide range of issues pertaining to the state's electricity, natural gas, and transportation fuel sectors. The EAP is intended to capture recent changes in the policy landscape and describe activities to accomplish those policies (Energy Commission and CPUC 2008).

In its discussion on energy efficiency, the 2008 EAP update refers to strategies identified in the 2006 *California Climate Action Team Report*, explaining that "nearly one-quarter of the emission reductions identified from existing or known strategies in 2020 would come from some form of energy efficiency investment, either through improved building codes or appliance standards, utility energy efficiency programs, or smart growth strategies" (Energy Commission and CPUC 2008). The 2008 EAP update discusses the significance of AB 2021, which was enacted in 2006 to further the goal of achieving all cost-effective energy efficiency. AB 2021 requires the Energy Commission, in consultation with CPUC, to develop statewide energy efficiency potential estimates and targets for California's investor-owned and publicly owned utilities. Progress toward meeting the targets is reported in the last biennial IEPR (Energy Commission 2012b). In December 2011, Energy Commission staff published the final report, *Achieving Cost-Effective Energy Efficiency for California 2011–2020*, which summarizes utility progress and recommends improvements for publicly owned utility efficiency efforts (Energy Commission 2012b).

The 2008 EAP update also discusses CPUC's strategic planning process to develop comprehensive, long-term strategies for making energy efficiency a way of life for Californians. CPUC adopted California's first *Long-Term Efficiency Strategic Plan* in 2008, which was developed through a collaborative process with CPUC's regulated utilities—PG&E, SCE, SDG&E, and Southern California Gas Company—and many other key stakeholders. The long-term plan provides a statewide roadmap to maximize achievement of cost-effective energy efficiency in California's electricity and natural gas sectors from 2009 through 2020 and beyond. CPUC's 2011 update to the *Energy Efficiency Strategic Plan* (CPUC 2011) is a comprehensive plan with goals and strategies covering all major economic sectors in the state.

As described in the 2011 IEPR, California's energy efficiency policies, programs, and energy standards for buildings and appliances in the last three decades have contributed to keeping the state's per capita electricity consumption relatively constant while energy use in the rest of the country has increased by approximately 40 percent (Energy Commission 2012b). In addition to achieving all cost-effective energy efficiency, California's energy efficiency policies include reducing energy use in existing buildings and achieving *zero net energy* building standards. Reducing building energy use to zero net energy is accomplished by combining greater energy efficiency and on-site clean energy production.

In its discussion on reducing energy use in existing buildings, the 2011 IEPR states that more than half of the state's 13 million residential units and more than 40 percent of commercial buildings were built before building and appliance efficiency standards were implemented (Energy Commission 2012b). AB 758 directed the Energy Commission to develop, adopt, and implement a comprehensive statewide program to reduce energy consumption in existing buildings and report on that effort in the IEPR. The Energy Commission shares responsibility with CPUC, local governments, and utilities to coordinate residential and commercial building retrofit programs. Completion of needs assessments and development of action plans is continuing. Other joint efforts are planned and intended to achieve improved compliance with building and appliance standards and ensure that energy efficiency measures and equipment are properly installed and delivering savings.

The Energy Commission, CPUC, and the California Air Resources Board have adopted a goal of achieving zero net energy building standards by 2020 for residential buildings and 2030 for commercial buildings (Energy Commission 2012b). In June 2011, CPUC released its *2010–2012 Zero Net Energy Action Plan* for the commercial building sector. The Energy Commission regularly updates its building efficiency standards to reflect new technologies and strategies consistent with the goal of achieving 20 to 30 percent energy savings in each triennial update. Appliance standards are being updated to include electronics and other devices plugged into electrical outlets.

Decision to Eliminate Energy Efficiency Strategies from Detailed Consideration as an Alternative to the PSEGS

The loading order specified in the EAP does not bind the Energy Commission to analyze particular project alternatives, and energy efficiency measures alone would not satisfy the project objectives and are not intended to replace all central station renewable energy facilities in the state. The proposed PSEGS does not reduce or eliminate opportunities for promoting conservation and energy efficiency in the state.

ALTERNATIVES EVALUATED IN DETAIL

CEQA requires consideration of “a reasonable range of potentially feasible alternatives that will foster informed decision making and public participation. An EIR is not required to consider alternatives which are infeasible” (Cal. Code Regs., tit. 14, § 15126.6[a]). Feasible is defined as “capable of being accomplished in a successful manner within a reasonable period of time, taking into account economic, environmental, legal, social, and technological factors” (Cal. Code Regs., tit. 14, § 15364).

Project alternatives were selected based on their potential to satisfy most of the basic project objectives discussed above under, “Alternatives Screening and Project Objectives,” and their potential to reduce or avoid the significant impacts identified for the proposed modified project.

Staff has selected three project alternatives for full analysis and comparison to the proposed modified project:

- No-Project Alternative
- Solar Photovoltaic Alternative with Single-Axis Tracking Technology
- Reduced Acreage Alternative with Solar Power Tower Technology

The proposed PSEGS would contribute to a net reduction in GHG emissions from power generation. Net GHG emissions for the state’s integrated electric system will decline when new renewable power plants are added that: (1) meet eligibility requirements for renewable energy resources in the state; (2) improve the overall efficiency, or GHG emission rate, of the electric system; and (3) serve increasing load (i.e., energy use) or energy capacity needs more efficiently, and with fewer GHG emissions, compared to fossil-fueled generation. Each of the project alternatives would result in a net benefit in reducing GHG emissions. Because solar thermal power plants with energy storage may not require a natural gas supply for project operations, they may displace more fossil fuel use and are more effective at reducing GHG emissions compared to solar thermal power plants without energy storage. As discussed above, staff concludes that an SPT with energy storage alternative would not substantially reduce or avoid direct and indirect environmental impacts of the proposed PSEGS; therefore, an alternative with energy storage is not included in this alternatives analysis.

Summary discussions are provided below comparing the environmental effects of the proposed modified project to the project alternatives. Environmental impacts that could potentially occur under a project alternative but that would not occur under the PSEGS are also discussed. A summary table comparing the potential impacts of the proposed modified project to the potential impacts of the project alternatives is provided in **ALTERNATIVES APPENDIX-2**.

NO-PROJECT ALTERNATIVE

Overview

The State CEQA Guidelines require that, among other alternatives, a no-project alternative shall be evaluated in relation to the proposed project. The no-project alternative analysis must “discuss the existing conditions at the time…environmental analysis is commenced, as well as what would be reasonably expected to occur in the foreseeable future if the project were not approved, based on current plans and consistent with available infrastructure and community services” (Cal. Code Regs., tit. 14, § 15126.6[e][2]). As required by CEQA, a No-Project Alternative has been included to allow a comparison of the impacts of approving the proposed PSEGS with the impacts of not approving the proposed PSEGS.

The State CEQA Guidelines discuss possible ways for the discussion of the no-project alternative to proceed. “If disapproval of the project under consideration would result in predictable actions by others, such as the proposal of some other project, this ‘no project’ consequence should be discussed. In certain instances, the no project alternative means ‘no build’ wherein the existing environmental setting is maintained. However, where failure to proceed with the project will not result in preservation of existing environmental conditions, the analysis should identify the practical result of the project’s non-approval and not create and analyze a set of artificial assumptions that would be required to preserve the existing physical environment” (Cal. Code Regs., tit. 14, § 15126.6 [e][3][B]).

The PSEGS site was previously approved by the Energy Commission for development of two, adjacent and identical 250-MW parabolic trough power plants with a net generating electrical capacity of 500 MWs. Reconfigured Alternatives #2 and #3 both received the Energy Commission’s approval in December 2010 (Energy Commission 2010a). Staff considers construction and operation of either of the two approved alternatives at the PSEGS site a reasonably foreseeable outcome for use of the site should plans for the proposed modified project fail to proceed. For PSEGS, the No-Project Alternative evaluates the impacts of the proposed modified project to the impacts of constructing and operating either of the approved alternatives from the original proceeding for the PSPP. **Alternatives Figures 1a** and **1b** show the site layouts for Reconfigured Alternatives #2 and #3. Staff’s conclusions for the potential environmental impacts of the No-Project Alternative are based on the analyses and conclusions in the 2010 Commission Decision for the original PSPP.

The proposed PSEGS is located entirely on public lands under BLM management. As stated above, BLM published a draft SEIS for the PSEGS in July 2013 (BLM 2013a). BLM's alternatives analysis in the draft SEIS carried forward the Preferred Alternative and No Action Alternative A that were previously analyzed in the May 2011 final EIS on the PSPP[4]. As described in BLM's draft SEIS, No Action Alternative A would deny ROW application CACA-48810 for the PSEGS, and the ROW grant would not be authorized. BLM's alternatives analysis states that the Solar PEIS Plan Amendment identifying "the [PSEGS] area as suitable for any type of solar energy development would be in effect for future projects. This includes prioritization of solar energy development in the Solar Energy Zone" (BLM 2013a). BLM's description of No Action Alternative A implies that development of the PSEGS site for generation of solar energy is a probable outcome should the current ROW application be denied.

As described in the Commission Decision for the PSPP, development of a parabolic trough project using one of the two approved site plans would have an overall disturbance area of up to approximately 4,365 acres (Energy Commission 2010a). Reconfigured Alternative #2 would disturb about 35 more acres compared to Reconfigured Alternative #3. (As originally proposed, the total disturbance area may have included a relatively small number of acres for the generation tie-line and roadway connection outside of the project site.)

The site boundary for the previously approved Reconfigured Alternative #2 includes approximately 284 acres of private land. Reconfigured Alternative #3 includes one 40-acre parcel under private ownership. The original project applicant had an option to purchase the 40-acre parcel that was part of Reconfigured Alternative #3 (Energy Commission 2010a). The altered site boundary for the PSEGS avoids the privately-owned land that was inside the fence line for the previously approved alternatives.

The PSEGS site slopes gently from the southwest to the northeast with a decrease in elevation to the northeast. The site contains native vegetation, including vegetated and unvegetated ephemeral washes entering the site from the south and fanning out across the site as the slope decreases. The I-10 corridor and concomitant drainage improvements have impaired natural flows throughout the valley. Surface waters drain to the Palen Dry Lake, northeast of the modified project site, and remain wholly within the Chuckwalla Valley. The site borders an active sand transport corridor, and much of the site has sandy soils and is rather sparsely vegetated. Portions of the site are uneven and hummocky. The site is undeveloped and unimproved desert open space. No site grading or earth movement was initiated at the site following approval of the original PSPP, and site conditions are substantially the same as they were in 2009–2010 during the original proceeding.

---

[4] The Preferred Alternative evaluated by BLM is the same as the Energy Commission's approved alternatives for the PSPP; BLM's "Options 1 and 2" correspond to the Energy Commission's approved Reconfigured Alternatives #2 and #3.

Parabolic Trough Technology

A parabolic trough system converts solar radiation into electricity using sunlight to heat a thermal fluid, typically synthetic oil. Parabolic trough power plants like the approved PSPP consist of horizontal, trough-shaped solar collectors that are arranged in parallel rows and aligned on a north-south horizontal axis. Each parabolic trough collector has a linear parabolic-shaped reflector that focuses the sun's rays on a linear receiver tube (i.e., heat collection element) suspended at the focal point of the curve-shaped collector. The trough rotates east to west to track the sun during the day, heating the heat transfer fluid (HTF) circulating in the collection element. The heated HTF is then piped through a series of heat exchangers where it releases its stored heat to generate high pressure steam. The steam is then fed to a traditional steam turbine generator where electricity is produced. **Alternatives Figures 2a** and **2b** show photographs of parabolic trough project facilities.

Beginning in 1984, nine solar power plants using parabolic trough technology were constructed in the Mojave Desert in San Bernardino County. Solar Electric Generating Systems (SEGS) III through VII are at Kramer Junction (**Alternatives Figure 2a**), SEGS VIII and IX are at Harper Lake, and SEGS I and II are at Daggett near Barstow. The nine SEGS projects have a combined total capacity of 354 MWs. Natural gas-fired facilities provide additional operational flexibility for each of the SEGS projects. These power plants cover a combined total of more than 1,600 acres.

In 2008 and 2009, the Energy Commission received AFCs for several renewable energy projects that were proposed to use parabolic trough technology, including the PSPP. Staff is monitoring construction of two of the projects that were licensed by the Energy Commission in September 2010—the Abengoa Mojave Solar Project (AMSP) and the Genesis Solar Energy Project (GSEP).

AMSP is near Harper Lake in San Bernardino County, about 9 miles northwest of the community of Hinkley. The SEGS VIII and IX facilities are immediately northwest of the AMSP site. GSEP is in the Sonoran Desert of east central Riverside County, about 25 miles west of Blythe. Each project consists of two 125-MW power plants for a combined total capacity of 500 MWs. Commercial operation of AMSP is anticipated in July 2014. Commercial operation of the two GSEP power plants is anticipated to occur consecutively in November 2013 and the second quarter of 2014. When construction of AMSP is finished, it will cover approximately 1,765 acres. GSEP will cover approximately 1,800 acres. Natural gas-fired auxiliary boilers will provide equipment and HTF freeze protection for each 125-MW power island for the two projects. AMSP will use wet cooling, and maximum operational water use for the project will total approximately 2,160 afy. GSEP will use dry cooling, requiring approximately 202 afy. The proposed PSEGS would require approximately 201 afy for project operations.

Construction and operation of the proposed PSEGS, including the common area and construction laydown area, would cover approximately 3,794 acres. Staff assumes that the disturbance area for the No-Project Alternative with construction of either Reconfigured Alternative #2 or #3 would affect an area up to roughly 570 acres larger than the area for the proposed modified project.

Site grading and earthwork for a parabolic trough project generally requires removal of all vegetation and mass grading to level the site. The approved PSPP would require excavation for foundations and underground systems and a total cut and fill volume of approximately 4.5 million cubic yards (Energy Commission 2010a). The proposed PSEGS would require approximately 0.2 million cubic yards of cut and fill (Palen Solar Holdings 2012).

Potential to Attain Project Objectives

Reconfigured Alternatives #2 and #3 both received the Energy Commission's approval in December 2010; therefore, this alternative (i.e., the No-Project Alternative) would satisfy the project objective addressing development of a solar thermal power plant at a site where some authorizations for construction have been obtained. This alternative would satisfy the project objective to develop a site that is in a BLM-designated SEZ. Staff assumes that this alternative could achieve the same energy capacity as the previously approved PSEGS, which was designed with an energy capacity of 500 MWs. This alternative could potentially contribute to meeting the state's RPS program goals. This alternative could potentially satisfy the project objectives addressing the requirement to comply with applicable laws, ordinances, regulations, and standards (LORS) and avoid or minimize significant impacts to the greatest extent feasible. This alternative would satisfy the project objective to develop a renewable energy facility in an area with high solar value and minimal slope.

Construction and operation of Reconfigured Alternative #2 or #3 could potentially satisfy most of the project objectives, although it is uncertain whether the change of technology back to parabolic trough would allow development of this alternative in a timely manner. See the discussions below under, "Environmental Analysis," for general analyses of the potential environmental effects of this alternative compared to the proposed modified project.

Potential Feasibility Issues

The Petition to Amend for the proposed modified project states that each of the two 250-MW units has an approved PPA (Palen Solar Holdings 2012). The project owner's objectives address fulfilling its existing approved PPAs for electrical sales from the facility. Approval of the PPAs by CPUC demonstrates that CPUC deems the PSEGS appropriate for helping to meet the state's RPS program goals. Once a PPA is approved, submittal of an amended advice letter to CPUC requesting an amended PPA is required unless the change to the project was accounted for in the original PPA (e.g., a PPA that allows a change in technology). It is unknown whether changing the technology of the PSEGS back to a parabolic trough project would require amending the PPAs. It is also unknown whether CPUC would approve amendments to the PPAs allowing the change, if such approvals would be necessary.

The Petition to Amend also states that Palen Solar Holdings has a Large Generator Interconnection Agreement (LGIA) with CAISO for 500 MWs of interconnection rights to deliver electricity from the PSEGS to SCE's Red Bluff Substation (Palen Solar Holdings 2012). CAISO is focused on advancing projects in the queue to commercial operation. A schedule delay could result in a project's failure to meet its milestones and a breach of the LGIA. Changing the project technology back to a parabolic trough technology could at least cause a project schedule delay, and it is not known at what point a project schedule delay would affect project viability.

BLM is considering the project owner's ROW application and revised POD for the PSEGS and has published a draft SEIS for the project (BLM 2013a). Changing the technology back to a parabolic trough project could require submittal of another revised POD to BLM, which would also delay the project schedule.

Environmental Analysis

Alternatives Table 1 summarizes the comparison of impacts of the proposed PSEGS to the same or similar potential impacts under the No-Project Alternative with construction and operation of either Reconfigured Alternative #2 or #3. Any differences in impacts that occur from comparing Reconfigured Alternative #2 and #3 to the proposed PSEGS are shown in the table. The comparisons of impacts to the proposed modified project are conveyed using these terms in a graded scale:

- Much less than PSEGS
- Less than PSEGS
- Somewhat less than PSEGS
- Similar to PSEGS
- Same as PSEGS
- Somewhat greater than PSEGS
- Greater than PSEGS
- Much greater than PSEGS

Impact conclusions for the proposed modified project and the comparative impacts for the alternatives are shown using these abbreviations:

— = no impact

B = beneficial impact

LS = less-than-significant impact, no mitigation required

SM or PSM = significant or potentially significant impact that can be mitigated to less than significant

SU or PSU = significant and unavoidable or potentially significant and unavoidable impact that cannot be mitigated to less than significant

For the following two topic areas, no comparative analysis of the alternatives is necessary:

- *Noise and Vibration*. No significant impacts are identified for the proposed modified project, and comparative noise and vibration impacts would be similar for the project alternatives; therefore, no comparative analysis is included for noise and vibration.
- *Transmission Line Safety and Nuisance*. The proposed modified project and the project alternatives would be installed at the PSEGS site, and the point of interconnection at the Red Bluff Substation would not change. The length and location of the 230-kV transmission line connecting the proposed modified project to the substation is assumed to be the same for the project alternatives. All federal, state, and local regulations and standard industry practices that apply to the proposed modified project would also apply to the project alternatives.

Comparative discussions for each environmental topic area listed below follow **Alternatives Table 1**. As stated above, **ALTERNATIVES APPENDIX-2** contains a complete summary table comparing the potential impacts of the proposed modified project to the potential impacts of the project alternatives.

Alternatives Table 1
Summary Comparison of Impacts of the Proposed PSEGS to the No-Project Alternative

Environmental Effect	Proposed PSEGS	No-Project Alternative
		Reconfigured Alternative #2 or #3
Air Quality		
Construction-related emissions	SM (locally)	Similar to PSEGS (SM)
Project operations emissions	SM (locally)	Somewhat greater than PSEGS (SM)
Reduction in greenhouse gases	B (system wide)	Similar to PSEGS (B)
Biological Resources		
Impacts on special-status plant species	SM	Greater than PSEGS (SM)
Impacts on waters of the state	SM	Much greater than PSEGS (SM)
Impacts on desert tortoise	SM	Greater than PSEGS (SM)
Impacts on special-status terrestrial wildlife species (kit fox, American badger)	SM	Greater than PSEGS (SM)
Potential impacts on avian species from collisions with project features	PSU	Similar to PSEGS (PSU)
Potential impacts on avian species from exposure to concentrated solar flux	PSU	—
Potential impacts on groundwater dependent ecosystems	SM	Somewhat greater than PSEGS (SM)
Impacts on sand transport corridor	SM	Somewhat less than PSEGS (SM)
Impacts on sand dunes and Mojave fringe-toed lizard	SM	Somewhat less than PSEGS (SM)
Cultural Resources		
Potential to substantively degrade, directly or indirectly, prehistoric or historical archaeological resources *on* the facility site, resources recommended or assumed to be historically significant *(see cultural resources note)*	PSM	Somewhat greater than PSEGS (SM)
Potential to substantively degrade, directly or indirectly, prehistoric or historical archaeological resources *beyond* the facility site, resources recommended or assumed to be historically significant	SU	Much less than PSEGS (SM)
Potential for cumulatively considerable degradation of prehistoric or historical archaeological resources *beyond* the facility site, resources recommended or assumed to be historically significant	SU	Much less than PSEGS (PSM)
Potential impacts on significant built-environment cultural resources *on* the site	LS	Similar to PSEGS (LS)
Potential impacts on a significant built-environment cultural resource (Desert Center) *beyond* the site	SU	Much less than PSEGS (LS)
Potential to substantively degrade, directly or indirectly, ethnographic resources *on* the facility site, resources recommended or assumed to be historically significant	PSM	Similar to PSEGS (PSM)

Alternatives Table 1
Summary Comparison of Impacts of the Proposed PSEGS to the No-Project Alternative

Environmental Effect	Proposed PSEGS	No-Project Alternative
		Reconfigured Alternative #2 or #3
Potential for cumulatively considerable degradation of ethnographic resources *on* the facility site, resources recommended or assumed to be historically significant	LS	Similar to PSEGS (LS)
Potential to substantively degrade, directly or indirectly, ethnographic resources *beyond* the facility site, resources recommended or assumed to be historically significant	SU	Much less than PSEGS (PSM)
Potential for cumulatively considerable degradation of ethnographic resources *beyond* the facility site, resources recommended or assumed to be historically significant	SU	Much less than PSEGS (PSM)
Cultural resources note: "Site" means the facility site proper and does not include linear or ancillary infrastructure away from the facility site.		
Fire Protection		
Construction-Related Impacts		
Impacts on the Riverside County Fire Department	SM	Somewhat greater than PSEGS (SM)
Project Operations Impacts		
Become familiar with and plan for emergency responses	SM	Less than PSEGS (SM)
Conduct plan reviews, inspections, and permitting	SM	Somewhat greater than PSEGS (SM)
Fire response	SM	Much greater than PSEGS (SM)
Hazardous materials spill response	SM	Much greater than PSEGS (SM)
Rescue	SM	Somewhat less than PSEGS (SM)
Emergency medical services	SM	Same as PSEGS (SM)
Geology and Paleontology		
Potential impacts from strong seismic shaking	SM	Much less than PSEGS (SM)
Potential impacts from soil failure caused by liquefaction, hydrocollapse, and/or dynamic compaction	SM	Much less than PSEGS (SM)
Potential impacts on paleontological resources	SM	Less than PSEGS (SM)
Potential impacts on geological or mineralogical resources	—	—
Hazardous Materials Management		
Construction-Related Impacts		
Potential for spills or other releases of hazardous materials to occur on-site	SM	Same as PSEGS (SM)
Potential for spills or other releases of hazardous materials to occur off-site	LS	Same as PSEGS (LS)
Project Operations Impacts		
Potential for spills or other releases of hazardous materials to occur on-site	SM	Much greater than PSEGS (SM)

Alternatives Table 1
Summary Comparison of Impacts of the Proposed PSEGS to the No-Project Alternative

Environmental Effect	Proposed PSEGS	No-Project Alternative
		Reconfigured Alternative #2 or #3
Potential for spills or other releases of hazardous materials to occur off-site	LS	Much greater than PSEGS (SM)
Land Use		
Compatibility with land use plan, policy, or regulation	SM	Somewhat greater than PSEGS (SM)
Public Health		
Potential for project construction to cause air toxics-related or other impacts that could affect public health	LS	Somewhat greater than PSEGS (LS)
Potential for project operations to cause air toxics-related or other impacts that could affect public health	PSM	Similar to PSEGS (PSM)
Socioeconomics		
Environmental justice population within 6-mile buffer.	—	—
Induce substantial population growth in an area, either directly or indirectly	LS	Similar to PSEGS (LS)
Displace substantial numbers of people and/or existing housing, necessitating the construction of replacement housing elsewhere	LS	Similar to PSEGS (LS)
Adversely impact acceptable levels of service for police protection, schools, and parks and recreation	LS	Similar to PSEGS (LS)
Increased property taxes, construction and operation employment income, and increased state and local taxes and fees	B	Similar to PSEGS (B)
Soil and Water Resources		
Soil erosion by wind and water during project construction	SM	Much greater than PSEGS (SM)
Soil erosion by wind and water during project operations	PSM	Less than PSEGS (PSM)
Water quality impacts from contaminated storm water runoff	SM	Somewhat greater than PSEGS (SM)
Water quality impacts from storm damage	PSM	Greater than PSEGS (PSM)
Water quality impacts from power plant operations	SM	Similar to PSEGS (SM)
Water quality impacts from sanitary waste	SM	Similar to PSEGS (SM)
Potential impacts from on-site and off-site flooding	PSM	Less than PSEGS (PSM)
Potential to impede or redirect 100-year flood flows, as shown on Federal Emergency Management Agency maps	—	—
Potential impacts on local wells	PSM	Somewhat greater than PSEGS (PSM)
Potential impacts on groundwater basin balance	PSM	Somewhat greater than PSEGS (PSM)

Alternatives Table 1
Summary Comparison of Impacts of the Proposed PSEGS to the No-Project Alternative

Environmental Effect	Proposed PSEGS	No-Project Alternative
		Reconfigured Alternative #2 or #3
Traffic and Transportation		
Potential damage to roads	PSM	Less than PSEGS (PSM)
Level of service on roads and highways – construction	PSM	Less than PSEGS (PSM)
Level of service on roads and highways – operation/post-construction	LS	Similar to PSEGS (LS)
Solar collector glint and glare impacts on motorists and pilots	PSM	Much less than PSEGS (PSM)
Solar receiver glare impacts that could be hazardous to motorists and pilots	PSM	Much less than PSEGS (LS)
Visual Resources		
Construction-Related Impacts		
Potential for adverse impacts on scenic vistas	SM	Greater than PSEGS (SM)
Potential to substantially damage scenic resources within a state scenic highway	LS	Similar to PSEGS (LS)
Potential to substantially degrade the existing visual character or quality of the site and its surroundings	SM	Greater than PSEGS (SM)
Potential to create a new source of substantial light or glare which would adversely affect day or nighttime views in the area	SM	Similar to PSEGS (SM)
Project Operations Impacts		
Potential for adverse impacts on scenic vistas	SU	Somewhat less than PSEGS (SU)
Potential to substantially damage scenic resources within a state scenic highway	LS	Similar to PSEGS (LS)
Potential to substantially degrade the existing visual character or quality of the site and its surroundings	SU	Less than PSEGS (SU)
Potential to create a new source of substantial light or glare which would adversely affect day or nighttime views in the area *(individual effects listed below)*		
Glint or glare effects from project structures other than the reflective surfaces of solar collectors (i.e., heliostats, parabolic troughs, PV panels)	SM	Similar to PSEGS (SM)
Glint or glare effects from the solar collectors	SM	Similar to PSEGS (SM)
Glint or glare effects from high-profile solar receiver steam generators	SU	—
Light or glare from nighttime lighting effects, including Federal Aviation Administration safety lighting	SM	Similar to or less than PSEGS (SM)
Waste Management		
Potential for unexploded ordnance to be present at the project site	PSM	Similar to PSEGS (PSM)
Potential for impacts on human health and the environment relating to past or present soil or water contamination	LS	Similar to PSEGS (LS)
Potential for impacts on human health and the environment	LS	Much greater than

Alternatives Table 1
Summary Comparison of Impacts of the Proposed PSEGS to the No-Project Alternative

Environmental Effect	Proposed PSEGS	No-Project Alternative
		Reconfigured Alternative #2 or #3
relating to potential waste discharges		PSEGS (PSM)
Potential for disposal or diversion of project materials to cause impacts on existing waste disposal or diversion facilities	LS	Similar to PSEGS (LS)

Air Quality

The number and type of emitting sources during project operations with implementation of the previously approved Reconfigured Alternative #2 or #3 (i.e., the No-Project Alternative for this analysis) would be similar to those of the proposed PSEGS; however, this alternative would use a heat transfer fluid (HTF) in the receiver tubes of the parabolic mirrors during project operations. When HTF leaks from project apparatus (e.g., piping, flanges, etc.), it vaporizes into small amounts of volatile organic compounds (VOCs), which are ozone precursors. The local air district would most likely require controls to minimize fugitive ozone precursor impacts at the project site. Overall, due to these VOC emissions, air quality impacts during project operation would be **somewhat greater than PSEGS**. Construction-related emissions and impacts would be **similar to PSEGS** for this alternative. Similar to the proposed modified project, this alternative would cause an overall, system wide, cumulative reduction in GHG emissions from power plants; because this alternative would require the use of auxiliary equipment necessary to operate a solar thermal power plant, the effect of reducing GHG emissions would be **similar to PSEGS**. However, more stringent mitigation measures would be required compared to the proposed modified project to ensure that the impacts from constructing and operating Reconfigured Alternative #2 or #3 would not be considered cumulatively significant for ozone.

Biological Resources

The proposed PSEGS would cover an approximately 3,794-acre site, a reduction in footprint of roughly 570 acres, or approximately 13 percent, as compared to Reconfigured Alternative #2, which has a slightly larger footprint than Reconfigured Alternative #3. Therefore, impacts on desert tortoise (*Gopherus agassizii*) and other special-status terrestrial wildlife species such as kit fox (*Vulpes macrotis*) and American badger (*Taxidea taxus*) (excluding Mojave fringe-toed lizard), as well as impacts on special-status plant species, would all be **greater than PSEGS**.

Either Reconfigured Alternatives #2 or #3 would cause adverse impacts on Mojave fringe-toed lizard (*Uma scoparia*), and these impacts were considered mitigable in the 2010 Commission Decision for the original PSPP. Impacts on sand dune habitat and sand transport corridors, and the Mojave fringe-toed lizard have been modeled independently by staff (Desert Research Institute 2013) and assessed by the project owner (Palen Solar Holdings 2013). While the outcomes of these modeling efforts are somewhat inconsistent, some trends are clear. In general, for the No-Project

Alternative, direct effects on sand transport corridor Zones II and III would be **somewhat less than PSEGS**. Indirect effects on Zone II and Zone III would also be **somewhat less than PSEGS** for the No-Project Alternative. Although Mojave fringe-toed lizard habitat largely encompasses sand dunes, this species uses other areas for foraging and to move from patch to patch of sand dune habitat. The distribution of Mojave fringe-toed lizards is naturally fragmented because of its obligate habitat specificity to loose sand, which is a patchy habitat type. Many local populations of this species are quite small, with small patches of sand supporting small populations of lizards. Environmental changes that stabilize sand, affect sand resources, or block sand movement corridors would also affect this species. Therefore, impacts on Mojave fringe-toed lizard would be **somewhat less than PSEGS**.

Excluding habitat loss, adverse impacts on avian species stem from two primary sources: potential injury or mortality from collisions with project features, and potential injury or mortality from exposure to solar flux. Staff is not able to quantify the risk of collision from either project design feature; however, given that collisions have been documented at both parabolic trough facilities and power tower facilities, staff considers the risk of collisions to be **similar to PSEGS**. A parabolic trough facility would not concentrate solar flux; therefore, **no impacts** would occur from exposure to concentrated solar flux with implementation of Reconfigured Alternative #2 or #3.

Soil and Water Resources staff concludes that potential impacts on the groundwater basin would be somewhat greater than the PSEGS under Reconfigured Alternative #2 or #3. Underground water may be accessed by certain types of vegetation, called phreatophytic vegetation, or phreatophytes. Phreatophytic vegetation is rare, with limited distribution, and often supports rare or special-status plants and animals, and may, in certain cases, be themselves considered a special-status plant or habitat. Examples of groundwater dependent ecosystems and plants in the project vicinity include honey mesquite woodlands, alkali sink scrubs, playa lake beds, jackass clover stands, stabilized and partially stabilized dunes, and microphyll woodlands (ironwood and palo verde desert wash woodlands). Assuming that the ability of groundwater dependent ecosystems to access groundwater is directly proportional to the level of underground water, impacts on groundwater dependent ecosystems would be **somewhat greater than PSEGS**.

The project owner has proposed a low-impact design for the heliostat solar field. Under the proposed PSEGS, approximately 27 percent of the site would be completely developed, and the rest of the site would be largely undisturbed. However, ongoing vegetation management and operational activities such as mowing, vegetation removal, and mirror washing could continue to degrade remnant native habitat. Parabolic trough projects require leveled ground whereas the proposed PSEGS would not require complete site grading. Therefore, construction of either of the No-Project Alternative configurations (i.e., Reconfigured Alternative #2 or #3) would cause impacts on on-site drainages (and waters of the state) that would be **much greater than PSEGS**.

Cultural Resources

Construction and operation of Reconfigured Alternative #2 or #3 would increase the lateral extent and the depth of physical ground disturbance on the facility site due to the extensive earthwork that would be required for parabolic trough technology. Therefore, staff concludes that the potential for either reconfigured alternative to substantively degrade, directly or indirectly, significant prehistoric or historical archaeological resources *on* the facility site would be **somewhat greater than PSEGS**.

The greatest difference in the comparative impacts of Reconfigured Alternative #2 or #3 to the proposed PSEGS relates to the character of their respective vertical profiles. The vertical profile of parabolic trough structures would be far less intrusive compared to the PSEGS solar power towers topped by brightly glowing SRSGs. The reduced visual presence of the previously approved Reconfigured Alternative #2 or #3 decreases the potential for either alternative configuration to substantively degrade the historical significance, directly or indirectly, of the broad, landscape-scale archaeological resources that are of primary concern to staff, or of other archaeological resources *beyond* the facility site, and this impact would be **much less than PSEGS**. The profound visual intrusion that the proposed PSEGS 750-foot-tall solar power towers would cast across a significant portion of western Chuckwalla Valley far exceeds, in extent and disruptive character, the potential visual intrusion of the approved alternatives' parabolic troughs, which would be approximately 25 feet tall across the solar fields, or the approximately 100-foot-tall cooling tower structure that would be required for a parabolic trough project. Construction and operation of Reconfigured Alternative #2 or #3 would greatly reduce the severe degradation of the visual integrity of the subject resources compared to construction and operation of the proposed PSEGS. The consequent hampered ability of the resources to convey their historical significance would be far less severe with construction and operation of Reconfigured Alternative #2 or #3.

The potential impacts on built-environment resources from construction and operation of the proposed PSEGS vary greatly, for impacts on and off the facility site, and differ significantly from the potential impacts of Reconfigured Alternative #2 or #3. The potential impacts on built-environment resources *on* the facility site were determined to be less than significant in the Commission Decision for the PSPP. Staff concludes that the potential impacts of the proposed PSEGS on built-environment resources *on* the site would also be less than significant, and these impacts would be **similar to PSEGS**. Potential impacts on built-environment resources *beyond* the facility site were found to be less than significant under the original PSPP due to the parabolic trough project's relatively low vertical profile. As one consequence of the much higher vertical profile of the proposed PSEGS, which staff concludes would result in significant and immitigable impacts on off-site built-environment resources, construction and operation of Reconfigured Alternative #2 or #3 would cause impacts on built-environment resources that would be **much less than PSEGS**.

No specific, unique and discrete known ethnographic resources are located within the physical footprints of the approved sites for the PSPP or the proposed PSEGS site. However, a larger cultural landscape with ethnographic, associative, and information values covers much of Chuckwalla Valley, including the PSEGS site, and the flanks of the surrounding mountains. Staff's comparative alternatives analysis of ethnographic resources considers the impacts of the project alternatives on the ethnographic values of the larger surrounding cultural landscape as a whole, and the ethnographic values of 11 traditional cultural places, all of which are *beyond* the respective footprints of Reconfigured Alternative #2 or #3 and the proposed PSEGS. These traditional cultural places are all contributing elements to the larger landscape. Because the geographic extent of the cultural landscape is much greater than that of the proposed PSEGS facility site, or those of the previously approved alternatives, impacts on the parts of the subject landscape that include any of those facility sites would be **similar to PSEGS** and could be reduced to less than significant with implementation of appropriate mitigation measures. However, beyond the PSEGS footprint, the severity of the visual intrusions of the parabolic trough technology of the previously approved alternatives would be greatly decreased compared to the direct impacts of the solar power towers of the proposed PSEGS. As a consequence, the impacts of Reconfigured Alternative #2 or #3 would be **much less than PSEGS**.

The potential cumulative impact of Reconfigured Alternative #2 or #3 on the full complement of cultural resources *beyond* the facility site, archaeological, built-environment, and ethnographic resources, would be **much less than PSEGS**. Due to the scarcity of more robust information on the character of the inventory of cultural resources beyond the facility site, staff assumes at least the possibility of a significant visual impact; however, the scope of the area in which the previously approved alternatives have the potential to cast such an effect, relative to any number of the Mojave Desert's landscape-scale cultural resources, makes it unlikely that the impact would be cumulatively considerable. Any significant direct, indirect, or cumulative visual impact that would occur from construction and operation of Reconfigured Alternative #2 or #3, given such an impact's potential to be noticeable compared to the landscape-scale resources, could most likely be reduced to less than significant with implementation of appropriate mitigation measures.

Fire Protection

Fire protection services include six areas where the Riverside County Fire Department (RCFD) would provide services and encumber significant time and funds that would have to be mitigated regardless of the technology proposed at a utility-scale solar plant site (e.g., the proposed PSEGS site):

1. Become familiar with and plan for emergency responses to a facility using a solar energy technology new to Riverside County

2. Conduct plan reviews, inspections, and permitting

3. Provide fire response

4. Provide hazardous materials (hazmat) spill response

5. Provide rescue

6. Provide Emergency Medical Services (EMS)

Construction-Related Impacts

Compared to the proposed PSEGS, construction of the previously approved Reconfigured Alternative #2 or #3 would require approximately the same level of service from the RCFD, and impacts on the RCFD would be approximately the same as the proposed PSEGS. Of the services listed above, construction of Reconfigured Alternative #2 or #3 using parabolic trough technology would require a somewhat greater level of effort to conduct plan reviews, inspections, and permitting.

The need for fire response would increase under this alternative near the end of construction and just prior to commissioning/operations when these activities would occur simultaneously. The increased need for fire response would relate to the presence at the site of very large volumes (over 2 million gallons) of HTF and an increased risk of explosion and fire from two large propane tanks.

Hazardous materials use during construction activities would remain about the same for all alternatives compared to the proposed modified project. During construction of any large-scale desert solar project, hazardous materials would include use of paint, solvents, gasoline, diesel fuel, motor oil, lubricants, and welding gases. Impacts on the RCFD from hazardous materials use during construction would be about the same as the proposed PSEGS. However, due to the on-site presence of very large volumes of HTF and other larger amounts of hazardous materials, this alternative would increase the need for hazmat spill response near the end of construction and prior to commissioning/operations when these activities would overlap. Because a parabolic trough project does not include construction of extremely tall structures analogous to the 750-foot SPTs of the proposed PSEGS, construction of Reconfigured Alternative #2 or #3 would not have the added construction safety concern and the potential need to conduct a high-angle technical rescue in the event of worker injury.

During the construction phases of large-scale desert solar projects, site grading, construction of buildings and solar collectors, and structures that are similar to those required at traditional power plant facilities would occur in a very hot desert environment. The work would subject workers to potential heat stress that could require EMS response. The impacts on EMS response would be approximately the same regardless of the solar technology.

Overall, construction-related direct and cumulative impacts on the RCFD under the No-Project Alternative would be **somewhat greater than PSEGS**.

Project Operations Impacts

Operation of Reconfigured Alternative #2 or #3 (parabolic trough technology) would require use of vast amounts of HTF while solar power tower technology does not use any similar HTF. HTF is a highly combustible mixture of two hydrocarbons that is also highly flammable at operating temperatures and pressures. Solar parabolic trough technology also requires use of large amounts of other hazardous materials such as acids and caustics, and the originally licensed project would also require storage of large amounts of propane, a highly flammable gas that poses a significant risk of explosion and off-site consequences. Therefore, implementation of the previously approved Reconfigured Alternative #2 or #3 would result in the operation of a solar power plant that would involve the transportation, storage, and use of very large amounts of hazardous materials. The risk of an accidental release or spill would be much greater than PSEGS. Impacts on fire response and hazardous materials spill response would be **much greater than PSEGS** for the No-Project Alternative. A somewhat greater level of effort relating to plan reviews, inspections, and permitting would increase impacts on the RCFD compared to the proposed PSEGS. This impact would be **somewhat greater than PSEGS**.

Operation of a solar parabolic trough power plant would not have workers in an enclosed 750-foot-tall SPT and thus the need for a high-angle technical rescue of an injured worker would not be present under this alternative. Impacts on rescue services would be **somewhat less than PSEGS**.

Geology and Paleontology

Significant paleontological resources have been documented within Pleistocene sediments in the site vicinity. Similar deposits of high paleontologic sensitivity are likely to be present at the site beneath a thin veneer of recent (Holocene) alluvium of low paleontologic sensitivity at an undetermined but potentially shallow depth.

Construction of the previously approved Reconfigured Alternative #2 or #3 would require substantial site grading and excavation. These activities would include site leveling, establishment of drainage systems and structures, excavation of trenches for pipelines and utilities, excavations for ancillary structure foundations, and drilled shaft foundations for support of parabolic trough mirror sections. Installation of a parabolic trough system would involve construction of parallel rows of mirrors suspended on level, linear lattice structures supported by drilled pier foundations. Using conventional excavation methods, fossils encountered during construction would be uncovered, discovered, collected and recorded, thereby contributing to the scientific understanding of the paleoclimate and paleobiology of the area.

The proposed PSEGS would use a different construction method. The PSEGS would involve installation of approximately 170,000 individual pole structures (pylons) to support heliostat mirrors in a concentric ring configuration. The pylons would be installed by vibro-insertion methods. Each pylon would be attached to a specialized piece of equipment that would drive each pylon through the soil column to a final depth of approximately 12 feet below ground surface. This method of construction does not use excavation, and there is no retrieval of subsurface soils or any fossils contained within those soils. In effect, any fossils that are in the path of pylon insertion would be permanently destroyed with no recovery, discovery or scientific benefit realized.

Given the construction method and number of heliostat pedestal foundations proposed for the PSEGS project, staff concludes in the **GEOLOGY AND PALEONTOLOGY** section of this staff assessment that the potential impact on paleontological resources is significant. To mitigate the impact on paleontological resources, staff recommends that a subsurface site characterization be conducted in the solar field prior to the start of ground disturbance. The characterization will allow for the refinement of various mitigation options, including fossil recovery and data collection, avoidance, and modification of pylon insertion to be implemented as appropriate to ensure significant impacts are mitigated to a less-than-significant level.

Staff concludes that even though mitigation measures would be accomplished prior to construction of the proposed PSEGS, the extensive excavation during construction of either Reconfigured Alternative #2 or #3 would result in the discovery, recovery, and curation of an abundance of fossils that could be present in subsurface soils. Therefore, the overall impacts on paleontological resources from construction of either Reconfigured Alternative #2 or #3 would be **less than PSEGS**. Under the No-Project Alternative, implementation of appropriate mitigation measures would reduce potentially significant impacts on paleontological resources to less than significant.

The parabolic trough system that would be installed under Reconfigured Alternative #2 or #3 would not require the deep or otherwise specialized foundations that would be required for the tall solar receiver towers of the proposed PSEGS project. With the elimination of tall tower structures, either of the reconfigured alternatives would have a decrease in seismic susceptibility compared to the PSEGS.

The overall potential for impacts to occur from all identified geologic hazards for Reconfigured Alternative #2 or #3 would be **much less than PSEGS**. Mitigation measures to reduce the risk of damage to the facility from identified geologic hazards would remain the same regardless of the project technology.

The PSPP area is not currently used for mineral production, nor is it under claim, lease, or permit for the production of locatable, leasable, or salable minerals. Sand and gravel resources are present at the site and could potentially be a source of salable resources; however, such materials are present throughout the regional area such that the original PSPP would not cause a significant impact on the availability of such resources. There are no other known viable geologic or mineralogic resources at the project site. The overall impacts on geologic or mineralogic resources from construction and operation of Reconfigured Alternative #2 or #3 would be the same as the proposed PSEGS, and **no impact** would occur.

Hazardous Materials Management

Construction-Related Impacts

As described above under "Fire Protection," construction activities for large-scale desert solar projects involve the use of various hazardous materials. However, no acutely toxic hazardous materials would be used on any site during construction of the previously approved Reconfigured Alternative #2 or #3, and none of these materials would pose a significant potential for off-site impacts as a result of the quantities on-site, the materials' relative toxicity and physical state, and/or their environmental mobility. Any potential impact of spills or other releases of these materials would be limited to the site because of the small quantities involved, their infrequent use (and therefore reduced chances of release), and/or the temporary containment berms used by construction contractors. Petroleum hydrocarbon-based motor fuels, mineral oil, lube oil, and diesel fuel are all very low volatility and represent limited off-site hazards even when used in larger quantities. Construction-related impacts for hazardous materials management would be the **same as PSEGS**.

Project Operations Impacts

As described above under "Fire Protection," operation of Reconfigured Alternative #2 or #3 (parabolic trough technology) would require use of vast amounts of highly combustible HTF. Solar parabolic trough technology also requires use of large amounts of other hazardous materials and storage of large amounts of propane, a highly flammable gas. Therefore, implementation of the previously approved Reconfigured Alternative #2 or #3 would result in the construction and operation of a solar power plant that would involve the transportation, storage, and use of very large amounts of hazardous materials. The risk of an accidental release or spill would be **much greater than PSEGS** for the No-Project Alternative.

Land Use

The 2010 Commission Decision approved the site for development of a 500-MW parabolic trough project with an overall disturbance area of up to approximately 4,365 acres. As noted in the **LAND USE** section of this staff assessment, the proposed modified project would be located entirely on public land administered by BLM and within the federal California Desert Conservation Area (CDCA) Plan area. The project area is in the "Multiple-Use Class M" land use category, which allows construction and operation of electrical generation plants. As discussed above, the PSEGS site is encompassed by BLM's Riverside East SEZ. These designations also apply to the previously approved Reconfigured Alternatives #2 and #3.

Unlike the proposed PSEGS, the approved PSPP Reconfigured Alternatives #2 and #3 include some private land—284 acres for Reconfigured Alternative #2 and 40 acres for Reconfigured Alternative #3 (**Alternatives Table 2**).

Alternatives Table 2
Comparative Site Disturbance Areas for the No-Project Alternative

	No-Project Alternative	
Proposed PSEGS	**Reconfigured Alternative #2**	**Reconfigured Alternative #3**
3,794-acre overall disturbed area, including the 218-acre common area (acreage does not include linear features)	4,365-acre overall disturbance area, including about 284 acres of private land (acreage may not include linear features)	4,330-acre overall disturbance area, including a 40-acre private parcel (acreage may not include linear features)

The inclusion of private land would require compliance with the Riverside County General Plan; the Riverside County Desert Center Area Plan land designation, "Open Space Rural;" and the Zoning Code designations W-2 (Controlled Development Areas), N-A (Natural Assets), and General Provisions. Implementation of the previously approved Reconfigured Alternative #2 or #3 would also have to comply with Ordinance No. 348.4705 (approved in May 2013), which amended Riverside County's Ordinance 348 to permit "solar power plants" on lots ten (10) acres or larger with Riverside County's (County) approval of a conditional use permit (CUP). With implementation of Reconfigured Alternative #2 or #3, the County's requirement for a CUP would be subsumed in the Energy Commission's licensing process.

Reconfigured Alternative #2 or #3 would need to comply with Riverside County Board of Supervisors Policy Number-29 (B-29), which requires solar power plant owners to annually pay Riverside County $150 for each acre of land involved in the power production process. This payment would increase annually by 2 percent after 2013.

BLM did not finalize the Record of Decision (ROD), amend the CDCA Plan, or issue a right-of-way (ROW) grant for the original PSPP. In February 2013, the project owner submitted a revised Plan of Development to BLM for the PSEGS. Should BLM approve issuance of a ROW grant for the PSEGS, two CDCA Plan amendments would be required—one would allow the solar generation facility and the other would allow the generation tie-line outside of the designated corridor (BLM 2013a). Staff recommends Condition of Certification **LAND-1** for the proposed PSEGS, which requires the project owner to provide documentation of the approved BLM ROW grant and a project-specific amendment to the CDCA Plan prior to the start of construction. **LAND-1** would also apply to Reconfigured Alternative #2 or #3. Like the proposed PSEGS, construction and operation of Reconfigured Alternative #2 or #3 would require compliance with applicable federal land use LORS.

Alternatives Table 2 shows that the proposed PSEGS would disturb between 536 and 571 fewer acres compared to the PSPP depending on the site configuration. Staff concludes that because Reconfigured Alternative #2 or #3 would involve a greater amount of disturbed land and would require compliance with Riverside County LORS, land use impacts of this alternative would be **somewhat greater than PSEGS**.

Public Health

Construction-Related Impacts

Construction-related combustion emissions and impacts under Reconfigured Alternative #2 or #3 would be similar to the proposed PSEGS. Public health risks include exhaust from diesel-fueled engines (such as trucks, graders, cranes, welding machines, electric generators, air compressors, and water pumps). According to staff's analysis in the **PUBLIC HEALTH** section of this staff assessment, the calculated cancer risk and non-cancer Hazard Index from diesel particulate matter are all below the significance levels. Other potential risks to public health during construction relate to exposure to Valley Fever in contaminated soil and fugitive dust disturbed during site preparation. As for the concerns of Valley Fever affecting the general population, staff considers the mitigation measures proposed in the **AIR QUALITY** section of this staff assessment adequate to prevent all fugitive dust plumes from leaving the project site boundary. As long as the dust plumes are kept within the project boundary, no significant impact would remain concerning the potential for Valley Fever to adversely affect the general population and public health. Therefore, no significant construction-related impacts on public health would occur, and no mitigation measures are required.

However, the PSEGS site is in an area where Valley Fever is endemic. Construction could disturb a certain percentage of top soil that could harbor the *Coccidioides* spores, possibly exposing humans to the risk of Valley Fever. People such as on-site workers could be exposed from inhaling these fungal spores from wind-blown dust generated from soil excavation during construction activities. Parabolic trough technology requires significant grading and leveling of the site, and disturbance of the top soil during construction and the quantity of cut and fill would be greater compared to the proposed PSEGS. Also, the project footprint of the proposed PSEGS (3,794 acres) is less than either Reconfigured Alternative #2 (4,365 acres) or Reconfigured Alternative #3 (4,330 acres). The reduced project footprint under PSEGS would also reduce the total area of disturbance and decrease the potential risk of exposure to Valley Fever. Because of the slightly increased risk of exposure to Valley Fever under the No-Project Alternative, public health impacts during project construction would be **somewhat greater than PSEGS**.

Project Operations Impacts

Operation of the previously approved Reconfigured Alternative #2 or #3 would require the use of similar equipment and apparatus for project operations compared to the proposed PSEGS. For both technologies, toxic air emissions would occur from auxiliary boilers, nighttime preservation boilers, wet surface air condenser (WSAC) units, emergency electric generator systems, emergency fire pump systems, and vehicles and equipment that would be used to clean the mirrors. Therefore, during project operations, the amounts and types of air toxics emitted by Reconfigured Alternative #2 or #3 would be similar to those emitted by the proposed PSEGS. Such emissions would occur at low levels, and this alternative would not pose a significant risk from the emissions of concern in the public health analysis.

For both technologies, the potential exists for bacterial growth (i.e., *Legionella*) to occur in the cooling towers and structures of the power plant cooling systems such as the WSAC in the proposed PSEGS. The public health impact from potential exposure to *Legionella* would be **similar to PSEGS**. For PSEGS, the impact is reduced to less than significant with implementation of Condition of Certification **PUBLIC HEALTH-1**. The same mitigation measure would apply to Reconfigured Alternative #2 or #3.

Reconfigured Alternative #2 or #3 would require use of an HTF in the receiver tubes of the parabolic mirrors during project operations. The HTF could cause emissions of small amounts of VOCs from potential leaks of HTF from flanges or that could be lost during routine maintenance activities such as HTF pipeline repair or replacement. Potential VOC emissions would occur at low levels and would not pose a significant public health risk; therefore, the public health impacts under this alternative would be **similar to PSEGS**.

Socioeconomics

The No-Project Alternative would require a smaller construction workforce, a larger operations workforce, and a longer construction period.

Staff concludes in the **SOCIOECONOMICS** section of this staff assessment that construction and operation of the PSEGS would not cause a significant adverse direct or indirect impact or contribute to a cumulative socioeconomic impact on the area's housing, schools, law enforcement services, or parks and recreation. Staff also concludes that the proposed modified project would not induce substantial population growth or displacement of population, or induce substantial increases in demand for housing, parks, or law enforcement services. Even with the increase in the operations workforce and construction schedule, the socioeconomic impacts of this alternative would be **similar to PSEGS**.

Construction and operation of this alternative would generate employment income and associated state and local sales taxes similar to what would be generated for the proposed PSEGS. Section 17620 of the Education Code (school impact fees) would not apply, as no habitable buildings would be constructed on private land. Property taxes would be assessed on the private land for the non-exempt improvements (Cal. Revenue and Taxation Code, § 73) associated with this alternative. The economic benefits would be **similar to PSEGS**.

Soil and Water Resources

The parabolic trough technology of the previously approved Reconfigured Alternative #2 or #3 would require traditional power plant facilities similar to PSEGS; therefore, potential impacts caused by the disposal of industrial wastewater would be **similar to PSEGS**. However, the added risk of accidental leaks or spills of HTF would increase the potential impacts of contaminated storm water runoff for the No-Project Alternative. This is an impact that would be unique to parabolic trough technology; therefore, potential impacts related to contaminated storm water runoff would be **somewhat greater than**

PSEGS. Domestic sanitary waste would still need a septic system for proper disposal, so these impacts would be the **similar to PSEGS**.

A technical limitation for parabolic trough facilities is the need for very flat terrain. Because the piping interconnecting the troughs has a very low tolerance for change in slope, the parabolic troughs need to be on less than 2 percent slope, and preferably less than 1 percent. The additional amount of total soil disturbance would significantly increase due to the need to level the site for installation of parabolic troughs. Although the project footprint of PSEGS is roughly 570 acres less (13 percent) than the footprint for the approved Reconfigured Alternative #2, the amount of earthwork required would be reduced by about 95 percent (0.2 million cubic yards compared to 4.5 million cubic yards). As a result, impacts related to soil erosion during construction would be **much greater than PSEGS** for either configuration of the No-Project Alternative.

The need for flat terrain results in very different approaches to storm water management between the two technologies. For both approved facility layouts of the No-Project Alternative, large channels would have been constructed just within the project borders to divert off-site flows away from the solar fields. These channels would help protect the site from off-site flows contributing to on-site flooding. Because the proposed PSEGS would allow existing on-site flooding to continue, impacts from on-site flooding of the No-Project Alternative would be **less than PSEGS**. However, potential impacts of these diversion channels on water quality from storm damage would be **greater than PSEGS** because flows from multiple existing ephemeral channels would combine, which would increase discharge rates and runoff volumes. Implementation of mitigation measures would reduce potential storm damage impacts to less than significant. Impacts from 100-year flood flows (as shown on the Federal Emergency Management Agency [FEMA] maps) do not apply because the published maps show that the 100-year flood plain is not present at or near the proposed PSEGS site.

Both configurations of the No-Project Alternative would utilize soil stabilizers within the solar fields to reduce the amount of dust deposited on the solar collectors (dust adversely affects the efficiency of solar trough technology). Therefore, despite the fact that many more acres of land would be graded and leveled, impacts relating to soil erosion during operations likely would be **less than PSEGS**. In addition, the flat slopes and grading would prevent on-site runoff from concentrating, resulting in shallow sheet flow which minimizes the potential for surface erosion.

Parabolic trough technology and solar power tower technology employ a similar steam cycle, so operational water use for the No-Project Alternative would be similar to PSEGS because both projects would use dry cooling. However, the overall water use of the No-Project Alternative would be much greater than PSEGS, roughly twice as much (14,750 acre-feet [af] compared to 7,160 af). This is due to the significant amount of earthwork during construction of the No-Project Alternative and increased water use for ongoing activities such as regular mirror washing of parabolic troughs compared to mirror washing of heliostats. For purposes of impact analysis, it is assumed that any withdrawals exceeding the average natural recharge and exceeding a significant percentage of the total amount of stored groundwater would cause a significant impact.

Because the Chuckwalla Valley Groundwater Basin (CVGB) is estimated to have a positive groundwater balance (inflow exceeds outflow) by approximately 2,600 afy, neither PSEGS nor the No-Project Alternative would result in basin overdraft. And although the difference in water use of the No-Project Alternative would be about 7,590 af more than PSEGS, total water use by the proposed PSEGS or this alternative would be very small compared to the CVGB storage capacity of 15,000,000 af. Because the PSEGS or this alternative would reduce the amount of total stored groundwater by less than a tenth of 1 percent, potential impacts of the No-Project Alternative on the CVGB and local well owners would generally be **somewhat greater than PSEGS**.

Traffic and Transportation

Potential Damage to Roads

During peak construction of the previously approved Reconfigured Alternative #2 or #3, the average daily workforce would be approximately 1,141 workers, which is less than the 2,311 workers required daily during peak construction of the proposed PSEGS. The number of daily one-way truck trips during peak construction of the original PSPP would be 40, which is less than the 90 peak daily one-way trips projected for the proposed PSEGS. Because the original PSPP would generate fewer construction and heavy-haul truck trips, road damage would be **less than PSEGS** under the No-Project Alternative. Mitigation measures similar to those recommended for the proposed modified project would reduce potential damage impacts on roadways to less than significant.

Level of Service on Roads and Highways – Construction

As discussed above, the No-Project Alternative would generate less construction traffic than the PSEGS; therefore, impacts on level of service (LOS) would be **less than PSEGS**. Like the proposed modified project, implementation of appropriate mitigation measures (e.g., a traffic control plan) would reduce this impact to less than significant.

Level of Service on Roads and Highways – Operation/Post-Construction

The number of daily operations employees required for the previously approved Reconfigured Alternative #2 or #3 is 134, which is more than the 100 daily employees needed for the proposed PSEGS. However, for both projects, the minimal number of trips generated by operations employees would have a negligible impact on traffic LOS. Therefore, impacts would be **similar to PSEGS**. No mitigation measures would be required.

Solar Collector Glint and Glare Impacts on Motorists and Pilots

The mirrored surfaces of various solar collectors are designed to concentrate the sun's rays on a receiver such as the SRSG at the top of the SPTs for the proposed modified project. The parabolic trough technology of Reconfigured Alternative #2 or #3 uses parabolic mirrors, which refocus solar radiation onto a receiver tube located at the focal point of the parabola. Highly reflective solar collectors from utility-scale solar projects have the potential to cause glint and glare effects and an intrusive bright nuisance, which can be distractive and uncomfortable to motorists and pilots in the area.

Compared to reflections from the proposed PSEGS's nearly planar heliostat mirrors, parabolic mirror reflections are much more diffuse and produce a greatly reduced glare effect as a function of viewing range. Therefore, solar collector glint and glare impacts under the No-Project Alternative would be **much less than PSEGS**. Mitigation measures similar to those recommended for the proposed modified project would reduce potential nuisance effects of glint and glare to less than significant.

Solar Receiver Glare Impacts That Could be Hazardous to Motorists and Pilots

Unlike the proposed PSEGS heliostats (mirrors) and SPTs, parabolic trough technology uses parabolic mirrors which refocus the radiation on a receiver tube located at the focal point of the parabola. Although the receiver tube glows and can be a source of glare, the receiver tubes are spatially distributed across the entire mirror field, as each individual receiver tube is associated with an individual parabolic mirror. This is unlike the PSEGS's brightly glowing solar receivers at the tops of the SPTs in which the glare source is concentrated at a single location from all of the active heliostat mirrors. Therefore, solar receiver glare impacts under the No-Project Alternative would be **much less than PSEGS**. Glare impacts from Reconfigured Alternative #2 or #3 would be less than significant, and no mitigation measures would be required. See the subsection below, "Visual Resources," for an assessment of the potential glint and glare effects of the alternatives on the visual and aesthetic environment.

Visual Resources

As described above, the PSEGS site was licensed by the Energy Commission in 2010 for construction and operation of either Reconfigured Alternative #2 or #3. Reconfigured Alternative #2 would consist of an approximately 4,365-acre parabolic trough solar energy project. This approved alternative would cover a larger area than the proposed 3,794-acre PSEGS, but would not include the SPTs topped by the brightly glowing SRSGs and the heliostats of the proposed PSEGS. Reconfigured Alternative #2, like the proposed PSEGS, would include a power transmission line from the project site extending westward to the Red Bluff Substation.

Compared to Reconfigured Alternative #2, Reconfigured Alternative #3 would disturb approximately 4,330 acres (an area less than 1 percent smaller) in a similar layout and location. Either approved alternative would employ the same technology and facilities and require the same transmission line to the Red Bluff Substation. For these reasons, Reconfigured Alternative #3 would have similar effects on scenic vistas, scenic resources, visual quality, and light and glare as Reconfigured Alternative #2.

Potential for Adverse Impacts on Scenic Vistas

Construction-Related Impacts: Construction of Reconfigured Alternative #2 or #3 (i.e., the No-Project Alternative) would cause temporary visual impacts due to the presence of equipment, materials, and a large workforce at the project site and along the transmission line route, an increase in visible traffic along I-10 and access roads, and large dust clouds generated by grading activities. A feature of parabolic trough technology is the need for very level sites over large areas. Consequently, required project grading during construction of Reconfigured Alternative #2 or #3 would be extensive. As described above, the approved parabolic trough alternatives of the PSPP would require a total cut and fill volume of approximately 4.5 million cubic yards whereas the proposed PSEGS would require approximately 0.2 million cubic yards of cut and fill. The proposed PSEGS heliostat mirror fields consist of independently mounted units that do not require project-wide grading or perfectly level sites. Consequently, grading-related construction impacts of this alternative on scenic vistas would be **greater than PSEGS**.

Project Operations Impacts: No designated scenic vistas were identified in the study area, but panoramic and highly scenic vistas from two BLM Wilderness Areas (Palen McCoy Wilderness and Chuckwalla Mountains Wilderness) would be affected by this alternative. Reconfigured Alternative #2 or #3 would not have two solar receivers with an extremely bright glare, but would have two fields of parabolic reflectors that would cover a larger area than the heliostat fields of the proposed PSEGS. This alternative would have similar industrial-type characteristics and be prominently visible from the two Wilderness Areas. The introduction of industrial characteristics and structural/textural visual contrast would result in substantial adverse effects on these scenic vistas. The impact on scenic vistas would be **somewhat less than PSEGS** because the solar trough alternatives would not have the strong form contrast of the two 750-foot-tall solar towers, or the strong glare contrast of the SRSGs at the tops of the SPTs. However, the parabolic trough structures would be approximately 25 feet tall, and the form/texture contrast of the parabolic trough mirror fields would be strong and would be a significant and unavoidable impact of implementing Reconfigured Alternative #2 or #3.

Potential to Substantially Damage Scenic Resources within a State Scenic Highway

The PSEGS site is located adjacent to the north side of I-10, which is not listed as an eligible State Scenic Highway, and no notable scenic features or historic structures are located within the site. Therefore, construction of Reconfigured Alternative #2 or #3 would not substantially damage scenic resources within a state scenic highway. This impact would be **similar to PSEGS**. The impact of operation of Reconfigured Alternative #2 or #3 on scenic resources within a state scenic highway would be **similar to PSEGS**.

Potential to Substantially Degrade the Existing Visual Character or Quality of the Site and its Surroundings

Construction-Related Impacts: As discussed above, the extent of site grading required for Reconfigured Alternative #2 or #3 would be greater than for the proposed PSEGS. Construction impacts of this alternative on visual quality would thus be **greater than PSEGS**.

Project Operations Impacts: Reconfigured Alternative #2 or #3 would introduce a field of prominent parabolic mirror structures with industrial characteristics into the views from State Route (SR) 177, the Desert Center area, I-10, Corn Springs Road, nearby Wilderness Areas, Joshua Tree National Park, and a few residences within the project viewshed. The area of Reconfigured Alternative #2 or #3 would be up to approximately 570 acres larger than PSEGS, but this alternative would not include the highly visible vertical structures of the SPTs or generate extreme glare from the SRSGs at the tops of the towers. However, the additional increment of form and glare contrast under the proposed PSEGS due to the very tall solar towers and brightly glowing solar receivers would be substantial compared to the approved parabolic trough projects. The impact of Reconfigured Alternative #2 or #3 on visual quality would thus be **less than PSEGS**, although this alternative would also result in a substantial degradation of the existing visual quality of the site and its surroundings.

Potential to Create a New Source of Substantial Light or Glare Which Would Adversely Affect Day or Nighttime Views in the Area

Construction-Related Impacts: Some construction activity could take place at night during construction of Reconfigured Alternative #2 or #3, with lighting impacts that would be **similar to PSEGS**.

Project Operations Impacts: Non-mirrored surfaces of the facilities of Reconfigured Alternative #2 or #3 (mirror support structures, mirror backs, power block generation facilities, operations and maintenance [O&M] facilities, etc.) could introduce reflected glare into the visual environment if the structures were light colored or included unpainted metal components, an impact that would be **similar to PSEGS**. Like the proposed modified project, with the effective implementation of Condition of Certification **VIS-1** requiring preparation and implementation of a surface treatment plan, Reconfigured Alternative #2 or #3 would not cause excessive glare from such non-mirrored components.

Glint effects, that is, inadvertent, very bright reflections of the sun’s image off the parabolic reflectors under certain conditions, could present a disruptive visual distraction for motorists and other viewers, which would represent a significant glint or glare impact of Reconfigured Alternative #2 or #3 due to the potential intensity of the effect. This glint impact would be **similar to PSEGS**. With implementation of proposed Condition of Certification **TRANS-7**, stray glint impacts from solar reflection off the heliostats under the proposed PSEGS would be less than significant. Although the causes of stray glint impacts are somewhat different under a parabolic trough project compared to the proposed PSEGS, similar mirror positioning and control and monitoring measures could be applicable to a parabolic trough project. Thus, staff assumes that inadvertent stray glint impacts could be reduced to a less-than-significant level with implementation of a similar mitigation measure under Reconfigured Alternative #2 or #3.

Compared to the proposed PSEGS, Reconfigured Alternative #2 or #3 would not include extremely tall solar towers with solar receivers, and would not generate strong on-going, operational SRSG glare that would be similar in any way to the proposed PSEGS. The impact of Reconfigured Alternative #2 or #3 due to on-going operational glare from solar receivers would not occur; therefore, **no impact** would occur compared to PSEGS.

Reconfigured Alternative #2 or #3 could generate nighttime light pollution from its operational lighting, and this impact would be **similar to PSEGS**. As with the proposed modified project, the effective implementation of Condition of Certification **VIS-4** (VIS-3 from the 2010 Commission Decision on the PSPP) would reduce this alternative's off-site, operation-related lighting impacts to less than significant.

Reconfigured Alternative #2 or #3 would not have solar towers that would require Federal Aviation Authority (FAA) safety lighting, and **no impact** would occur.

Waste Management

The Commission Decision for the original PSPP evaluated effects of the approved Reconfigured Alternatives #2 and #3 on waste management. Based on current estimates provided by the project owner, disposal of non-hazardous and hazardous waste generated by the proposed PSEGS would be approximately the same as the originally licensed project (i.e., the No-Project Alternative) and would not adversely impact either Class III or Class I landfill capacity. This impact would be **similar to PSEGS**. The original PSPP would require the use of HTF, which must be disposed of as a hazardous waste. The potential for discharge of HTF could result in significant environmental impacts. Because SPT technology does not use any similar HTF, this impact would be **much greater than PSEGS**.

Potential impacts relating to soil and water contamination and the potential presence of unexploded ordnance (UXO) at the site would be **similar to PSEGS**. A UXO Identification, Training, and Reporting Plan would still be required, which would include site worker training and procedures for UXO investigation, removal, and disposal.

SOLAR PHOTOVOLTAIC (PV) ALTERNATIVE WITH SINGLE-AXIS TRACKING TECHNOLOGY

Overview

Solar PV technology involves the direct conversion of photons (i.e., sunlight) into electricity. PV modules (also called solar panels) absorb solar radiation and convert it into direct current electricity. This direct current power is then converted into alternating current electricity for delivery to the electrical grid system. This conversion occurs when direct current (DC) flows through a device called an *inverter*, which converts the electrical characteristics to alternating current (AC) that can be tied to the power distribution system for power delivery. The electrical current produced is directly dependent on how much light strikes the module. Multiple PV panels are wired together to form an array, an arrangement that increases the total system output. PV technology does not involve thermal energy or the production of steam to power turbines. PV systems are relatively simple to operate and maintain and require little water for project operations compared to solar thermal energy systems.

The Solar PV Alternative would involve constructing and operating a utility-scale, single-axis tracking PV project at the proposed PSEGS site. PV trackers using single-axis (east-west) tracking maximize the panels' absorption of sunlight during the day and throughout the year. Tracking PV modules produce more electricity annually compared to fixed-tilt modules.

The April 2012 Desert Renewable Energy Conservation Plan Stakeholder Committee Meeting included a review of an update to the renewable energy calculator that was developed by Energy Commission staff to use as a tool for framing an understanding of renewable energy supply and demand for the 2040 planning horizon. Partly in response to comments on an earlier version of the 2040 planning scenario, the acreage requirement for all central station solar projects, including solar thermal and PV project types, was reduced from 9.1 acres per MW to 7 acres per MW. Although it was acknowledged at the meeting that scenarios will vary depending partly on the portfolio[5], the modified efficiency ratio is considered to be plausible and reasonable. Adjustments to the portfolio will be made every 5 years during the planning horizon.

Alternatives Table 3 lists five utility-scale, single-axis tracking PV projects that are approved and at different stages of development in California. Based on the generating capacities and acreage requirements for these sample projects, staff assumes that a single-axis tracking solar PV project with an electrical capacity similar to the proposed PSEGS could be constructed at the project site with no change to the site boundary. Operational water use for the PV projects listed in the table ranges from approximately 12.4 afy for the California Valley Solar Ranch Project to approximately 15–22 afy for the McCoy Solar Energy Project. The proposed modified project would require 201 afy for project operations.

The Solar PV Alternative would not require a natural gas supply; therefore, this alternative would not require a new extension of the existing Southern California Gas distribution system to the project site boundary.

The previous alternatives analysis for the licensed PSPP eliminated a utility-scale PV alternative from detailed consideration, stating that it would require more extensive site grading and a stormwater management system that would be greater than the PSPP (Energy Commission 2010b). Based on staff's current review of several utility-scale PV projects in the state, developers are installing systems that minimize site grading and removal of on-site vegetation. Site restoration and revegetation is typically required to repair and restore areas that were disturbed during construction. Similar to the supporting piers for the heliostats, PV module supports are installed to allow stormwater flows to cross the site. In addition to the projects shown in **Alternatives Table 3**, PV projects are being installed in the state to minimize site disturbance and avoid or minimize cut and fill grading, including the Desert Sunlight Solar Farm Project in the Chuckwalla Valley and the Topaz Solar Farm Project on the Carrizo Plain. Therefore, the analysis of the Solar PV Alternative in this staff assessment has conclusions that

[5] The portfolio includes central station solar thermal, central station PV, wind, biomass/fuels, geothermal, utility-side distributed generation, and small rooftop solar.

are different based on currently available information on potential environmental impacts from PV systems. Further details are provided following **Alternatives Table 3** on two of the PV projects reviewed by staff.

Alternatives Table 3
Summary Descriptions of Five Approved Single-Axis Tracking Photovoltaic Projects in California

California Valley Solar Ranch Project

The SunPower T0 Tracker® technology is described in the final environmental assessment (EA) for the California Valley Solar Ranch (CVSR) Project and provides an example of the type of technology that could potentially be installed at the PSEGS site. At the CVSR Project site on the Carizzo Plain, the T0 Tracker technology allows more efficient use of the site due to its tolerance for slope variations (DOE 2011). This tracker technology has a low profile, typically 5 to 6 feet above the ground when oriented in the horizontal position (or slightly higher in limited areas at the site with steeper slopes). No permanently shaded areas are created by the panels. The trackers use low-impact penetrating foundations that are driven directly into the ground without the need for concrete foundations. Each foundation has a footprint of approximately 4½ inches. The tracker and low-impact penetrating foundation structures and mechanical assemblies are made of galvanized steel. **Alternatives Figure 3a** shows a photograph of a typical T0 Tracker.

For the CVSR Project, the array blocks (i.e., sets of PV panels) cover approximately 6 to 6½ acres. The inverters (described above) are centrally located in each array block. Many array blocks compose a single array. **Alternatives Figures 3a and 3b** provide photographs of some of the single-axis tracking PV arrays at the CVSR Project site.

As described in the final EA for the CVSR Project, power is transmitted from the inverters to the substation through medium-voltage AC collection lines running underground and overhead. The poles supporting the medium-voltage AC lines are typically about 50 feet tall. The final EA estimates that the electrical collection lines will require approximately 200 utility poles. The power is converted from 34.5 kV to 230 kV at the CVSR Project substation. A new, approximately 4-mile-long overhead 230-kV interconnection line is connecting the CVSR Project to the existing PG&E 230-kV Morro Bay-Midway transmission line at a new switching station. **Alternatives Figure 4** shows the solar arrays and major project features for the CVSR Project for illustrative purposes. As depicted in **Alternatives Figure 4**, PV arrays may be configured in noncontiguous areas of different sizes and shapes.

Most of the CVSR Project will be constructed on approximately 1,500 acres. As described in the final EA for the CVSR Project, site preparation for installation of trackers requires grading of about 315 acres, excluding grading for fire access roads around the arrays (DOE 2011). The project's interior road system requires construction of approximately 24 miles of roadway covering about 80 acres. Of the total 1,500 acres, approximately 90 acres are expected to be subject to permanent disturbance. This acreage does not include construction of the interconnection line, which is expected to permanently disturb approximately 16 acres.

Installation of the SunPower T0 Tracker® system generally does not require grubbing (removal of vegetation); vegetation is only removed in areas where grading occurs. As described by a representative of the project developer for the CVSR Project, strict procedures are followed for top soil retention in disturbed areas (Ekstrom, pers. comm., 2013). Following ground disturbance, the top soil and seed bank that was removed during construction is returned and redistributed over the disturbed area to revegetate the site, in accordance with the agency-approved Habitat Restoration and Revegetation Plan. **Alternatives Figure 3a** includes a photograph showing grasses beneath the arrays.

McCoy Solar Energy Project

BLM recently issued the ROD approving construction and operation of the McCoy Solar Energy Project (MSEP), a 750-MW solar PV project in Riverside County near Blythe, California (BLM 2013b). The approved project will be constructed in two units with Unit 1 covering approximately 2,259 acres inside the project's fence line. Of that total, approximately 477 acres are under County jurisdiction and outside of BLM's right-of-way grant boundary; an EIR is being prepared by the County for the portion of the MSEP that will be constructed on private land. Unit 1 will have a generating capacity of up to 250 MW. The power generated by Unit 1 of the MSEP will be sold to Southern California Edison (SCE) under a PPA that was approved by CPUC in June 2012.

The project developer for the MSEP has not yet selected a solar panel supplier for Unit 1 (Neville, pers. comm., 2013). The panels will either be thin film (cadmium telluride [CdTe]) or polycrystalline silicon; either type of panel can be installed on a single-axis tracking system. The energy generation efficiency of the MSEP will vary depending on the type of panel that is selected and installed.

Because the MSEP site is nearly flat, minimal grading and earthwork will be used at the site (BLM 2013b). Stormwater drainage will be designed to maintain existing surface water hydrology and drainage wherever possible. PV tracking and framing structures will generally be installed to follow the existing land contours. Localized grading will be used only to compensate for major variations in topography while avoiding significant impacts on existing surface hydrology. Although not anticipated, if large areas require grading, a disc and roll technique would be used rather than conventional cut and fill grading (BLM 2012). Adopted mitigation measures include a measure (APM BIO-2p) to develop and implement a revegetation plan to restore temporarily disturbed areas (BLM 2013b). Even so, the biological resources analysis in the final EIS for the MSEP assumes that the entire MSEP site would be subject to permanent ground disturbance, including temporary laydown areas that would be converted to the solar field following construction (BLM 2012).

Potential to Attain Project Objectives

Ongoing approval and construction of utility-scale PV projects in California and Nevada indicate the suitability of using PV technology for development of a large, renewable energy power plant with a capacity of several hundred MWs. It is possible that the PSEGS 3,576-acre solar field area could be used for design and layout of a single-axis tracking PV project to achieve close to the 500-MW capacity of the proposed modified project. The site plan for the CVSR project shows noncontiguous polygons forming the array boundaries for that project (**Alternatives Figure 4**), which demonstrates that single-axis tracker systems do not necessarily require extensive, uninterrupted areas for the layout of solar array fields. Assuming that configuring a single-axis tracking PV project has some inherent flexibility, this alternative could potentially satisfy the project objectives to comply with applicable LORS and avoid or minimize significant impacts to the greatest extent feasible. The environment of the PSEGS site is unlike the CVSR project site on the Carrizo Plain, and further study would be necessary to devise a site plan for the layout of single-axis PV trackers at the PSEGS site. This alternative would satisfy the project objective to develop a renewable energy facility in an area with high solar value and minimal slope.

This alternative would not satisfy the project owner's objective to develop a solar thermal power plant at a site where some authorizations for construction have been obtained. The Energy Commission's prior licensing of the PSEGS site for a solar thermal electric generation facility would not apply to the Solar PV Alternative (see the discussion below under "Potential Feasibility Issues"). BLM would be the primary permitting authority, and staff assumes that submittal of a revised POD to BLM would be required. Given the change of permitting authority, it is unknown whether this alternative could satisfy the project objectives to construct and operate a utility-scale solar energy project and assist SCE in satisfying its RPS program goals.

The Solar PV Alternative could potentially satisfy many of the project objectives, although it is uncertain whether the change of technology would allow development of this alternative in a timely manner. See the discussions below under, "Environmental Analysis," for general analyses of the potential environmental effects of this alternative compared to the proposed modified project.

Potential Feasibility Issues

The Petition to Amend for the proposed modified project states that each of the two 250-MW units has an approved PPA with SCE (Palen Solar Holdings 2012). It is unknown whether changing the technology of the PSEGS to single-axis PV trackers would require amending the PPAs. It is also unknown whether CPUC would approve amendments to the PPAs allowing the change, if such approvals would be necessary.

As stated above, Palen Solar Holdings has an LGIA with CAISO for 500 MWs of interconnection rights to deliver electricity from the PSEGS to SCE's Red Bluff Substation (Palen Solar Holdings 2012). A schedule delay could result in a project's failure to meet its milestones and a breach of the LGIA. Changing the project technology to solar PV could at least cause a project schedule delay, and it is not known at what point a project schedule delay would affect project viability.

The Warren-Alquist Act was amended in 2012 to allow certain solar thermal power plants that were certified by the Energy Commission to be converted, in whole or in part, to a solar PV technology and reviewed by the Energy Commission as an amendment to the originally licensed project. For a project located on BLM-managed land, issuance of an ROD by BLM would have been required before September 1, 2011 (Pub. Resources Code, § 25500.1[a]). Because the PSPP did not receive an ROD, the Energy Commission would not retain jurisdiction if a change to a solar PV technology was proposed at the site. In this instance, BLM would be the primary permitting authority, and changing the project technology to solar PV at the PSEGS site would presumably require submittal of a revised POD to BLM, which would also delay the project.

Environmental Analysis

Alternatives Table 4 presents a summary comparison of impacts of the proposed PSEGS to the same or similar potential impacts of the Solar PV Alternative with Single-Axis Tracking Technology. Comparative discussions for each environmental topic area follow the table.

Alternatives Table 4
Summary Comparison of Impacts of the Proposed PSEGS to the Solar Photovoltaic Alternative with Single-Axis Tracking Technology

Environmental Effect	Proposed PSEGS	Solar PV Alternative
Air Quality		
Construction-related emissions	SM (locally)	Similar to PSEGS (SM)
Project operations emissions	SM (locally)	Less than PSEGS (SM)
Reduction in greenhouse gases	B (system wide)	Somewhat greater than PSEGS (B)
Biological Resources		
Impacts on special-status plant species	SM	Similar to PSEGS (SM)
Impacts on waters of the state	SM	Similar to PSEGS (SM)
Impacts on desert tortoise	SM	Similar to PSEGS (SM)
Impacts on special-status terrestrial wildlife species (kit fox, American badger)	SM	Similar to PSEGS (SM)
Potential impacts on avian species from collisions with project features	PSU	Similar to PSEGS (PSU)
Potential impacts on avian species from exposure to concentrated solar flux	PSU	—
Potential impacts on groundwater dependent ecosystems	SM	Somewhat less than PSEGS (SM)
Impacts on sand transport corridor	SM	Somewhat less than PSEGS (SM) *(see biological resources note)*
Impacts on sand dunes and Mojave fringe-toed lizard	SM	Somewhat less than PSEGS (SM) *(see biological resources note)*
Biological resources note: Comparative impacts for the Solar PV Alternative for indirect impacts on the sand transport corridor, sand dune habitat, and Mojave fringe-toed lizard cannot reasonably be characterized without further data and use of a sand transport model.		
Cultural Resources		
Potential to substantively degrade, directly or indirectly, prehistoric or historical archaeological resources *on* the facility site, resources recommended or assumed to be historically significant *(see cultural resources note)*	PSM	Similar to PSEGS (PSM)

Alternatives Table 4
Summary Comparison of Impacts of the Proposed PSEGS to the Solar Photovoltaic Alternative with Single-Axis Tracking Technology

Environmental Effect	Proposed PSEGS	Solar PV Alternative
Potential to substantively degrade, directly or indirectly, prehistoric or historical archaeological resources *beyond* the facility site, resources recommended or assumed to be historically significant	SU	Much less than PSEGS (SM)
Potential for cumulatively considerable degradation of prehistoric or historical archaeological resources *beyond* the facility site, resources recommended or assumed to be historically significant	SU	Much less than PSEGS (SM)
Potential impacts on significant built-environment cultural resources *on* the site	LS	Similar to PSEGS (LS)
Potential impacts on a significant built-environment cultural resource (Desert Center) *beyond* the site	SU	Much less than PSEGS (SM)
Potential to substantively degrade, directly or indirectly, ethnographic resources *on* the facility site, resources recommended or assumed to be historically significant	PSM	Similar to PSEGS (PSM)
Potential for cumulatively considerable degradation of ethnographic resources *on* the facility site, resources recommended or assumed to be historically significant	LS	Similar to PSEGS (LS)
Potential to substantively degrade, directly or indirectly, ethnographic resources *beyond* the facility site, resources recommended or assumed to be historically significant	SU	Much less than PSEGS (SM)
Potential for cumulatively considerable degradation of ethnographic resources *beyond* the facility site, resources recommended or assumed to be historically significant	SU	Much less than PSEGS (SM)
Cultural resources note: "Site" means the facility site proper and does not include linear or ancillary infrastructure away from the facility site.		
Fire Protection		
Construction-Related Impacts		
Impacts on the Riverside County Fire Department	SM	Much less than PSEGS (SM)
Project Operations Impacts		
Become familiar with and plan for emergency responses	SM	Much less than PSEGS (SM)
Conduct plan reviews, inspections, and permitting	SM	Much less than PSEGS (SM)
Fire response	SM	Much less than PSEGS (SM)
Hazardous materials spill response	SM	Much less than PSEGS (SM)
Rescue	SM	Somewhat less than PSEGS (SM)
Emergency medical services	SM	Much less than PSEGS (SM)
Geology and Paleontology		
Potential impacts from strong seismic shaking	SM	Much less than PSEGS (SM)
Potential impacts from soil failure caused by liquefaction, hydrocollapse, and/or dynamic compaction	SM	Much less than PSEGS (SM)

Alternatives Table 4
Summary Comparison of Impacts of the Proposed PSEGS to the Solar Photovoltaic Alternative with Single-Axis Tracking Technology

Environmental Effect	Proposed PSEGS	Solar PV Alternative
Potential impacts on paleontological resources	SM	Somewhat less than PSEGS (SM)
Potential impacts on geological or mineralogical resources	—	—
Hazardous Materials Management		
Construction-Related Impacts		
Potential for spills or other releases of hazardous materials to occur on-site	SM	Same as PSEGS (SM)
Potential for spills or other releases of hazardous materials to occur off-site	LS	Same as PSEGS (LS)
Project Operations Impacts		
Potential for spills or other releases of hazardous materials to occur on-site	SM	Much less than PSEGS (SM)
Potential for spills or other releases of hazardous materials to occur off-site	LS	Much less than PSEGS (LS)
Land Use		
Compatibility with land use plan, policy, or regulation	SM	Similar to PSEGS (SM)
Public Health		
Potential for project construction to cause air toxics-related or other impacts that could affect public health	LS	Similar to PSEGS (LS)
Potential for project operations to cause air toxics-related or other impacts that could affect public health	PSM	Less than PSEGS (LS)
Socioeconomics		
Environmental justice population within 6-mile buffer.	—	—
Induce substantial population growth in an area, either directly or indirectly.	LS	Similar to PSEGS (LS)
Displace substantial numbers of people and/or existing housing, necessitating the construction of replacement housing elsewhere.	LS	Similar to PSEGS (LS)
Adversely impact acceptable levels of service for police protection, schools, and parks and recreation.	LS	Similar to PSEGS (LS)
Increased property taxes, construction and operation employment income, and increased state and local taxes and fees.	B	Similar to PSEGS (B)
Soil and Water Resources		
Soil erosion by wind and water during project construction	SM	Somewhat less than PSEGS (SM)
Soil erosion by wind and water during project operations	PSM	Less than PSEGS (PSM)
Water quality impacts from contaminated storm water runoff	SM	Somewhat greater than PSEGS (SM)
Water quality impacts from storm damage	PSM	Somewhat greater than PSEGS (PSM)
Water quality impacts from power plant operations	SM	Much less than PSEGS (SM)
Water quality impacts from sanitary waste	SM	Similar to PSEGS (SM)
Potential impacts from on-site and off-site flooding	PSM	Similar to PSEGS (PSM)

Alternatives Table 4
Summary Comparison of Impacts of the Proposed PSEGS to the Solar Photovoltaic Alternative with Single-Axis Tracking Technology

Environmental Effect	Proposed PSEGS	Solar PV Alternative
Potential to impede or redirect 100-year flood flows, as shown on Federal Emergency Management Agency maps	—	—
Potential impacts on local wells	PSM	Somewhat less than PSEGS (PSM)
Potential impacts on groundwater basin balance	PSM	Somewhat less than PSEGS (PSM)
Traffic and Transportation		
Potential damage to roads	PSM	Less than PSEGS (PSM)
Level of service on roads and highways – construction	PSM	Less than PSEGS (PSM)
Level of service on roads and highways – operation/post-construction	LS	Similar to PSEGS (LS)
Solar collector glint and glare impacts on motorists and pilots	PSM	Much less than PSEGS (PSM)
Solar receiver glare impacts that could be hazardous to motorists and pilots	PSM	—
Visual Resources		
Construction-Related Impacts		
Potential for adverse impacts on scenic vistas	SM	Less than PSEGS (SM)
Potential to substantially damage scenic resources within a state scenic highway	LS	Similar to PSEGS (LS)
Potential to substantially degrade the existing visual character or quality of the site and its surroundings	SM	Similar to PSEGS (SM)
Potential to create a new source of substantial light or glare which would adversely affect day or nighttime views in the area	SM	Similar to PSEGS (SM)
Project Operations Impacts		
Potential for adverse impacts on scenic vistas	SU	Less than PSEGS (SU)
Potential to substantially damage scenic resources within a state scenic highway	LS	Similar to PSEGS (LS)
Potential to substantially degrade the existing visual character or quality of the site and its surroundings	SU	Less than PSEGS (SU)
Potential to create a new source of substantial light or glare which would adversely affect day or nighttime views in the area *(individual effects listed below)*		
Glint or glare effects from project structures other than the reflective surfaces of solar collectors (i.e., heliostats, parabolic troughs, PV panels)	SM	Much less than PSEGS (PSM)
Glint or glare effects from the solar collectors	SM	Much less than PSEGS (PSM)
Glint or glare effects from high-profile solar receiver steam generators	SU	—
Light or glare from nighttime lighting effects, including Federal Aviation Administration safety lighting	SM	Less than PSEGS (SM)
Waste Management		
Potential for unexploded ordnance to be present at the project site	PSM	Similar to PSEGS

Alternatives Table 4
Summary Comparison of Impacts of the Proposed PSEGS to the Solar Photovoltaic Alternative with Single-Axis Tracking Technology

Environmental Effect	Proposed PSEGS	Solar PV Alternative
		(PSM)
Potential for impacts on human health and the environment relating to past or present soil or water contamination	LS	Similar to PSEGS (LS)
Potential for impacts on human health and the environment relating to potential waste discharges	LS	Similar to PSEGS (LS)
Potential for disposal or diversion of project materials to cause impacts on existing waste disposal or diversion facilities	LS	Similar to PSEGS (LS)

Air Quality

The number of permitted fuel-consuming and air pollutant emitting sources would be significantly fewer under the Solar PV Alternative. Construction-related emissions and impacts would be **similar to PSEGS** for this alternative. Operational impacts relating to criteria pollutant emissions for a utility-scale PV project would include normal maintenance truck activity, possibly including periodic fire water pump engine testing, and use of water trucks coinciding with the infrequent work to wash the PV modules. Use of fossil fuel-fired supplemental boiler operation is not required under this alternative. Impacts on air quality from operation of the Solar PV Alternative would be **less than PSEGS**. The Solar PV Alternative would not require the auxiliary equipment (e.g., auxiliary boilers for freeze protection and fast startup) necessary to operate a solar thermal power plant; therefore, this alternative would generate GHG emissions that would be somewhat less than PSEGS. This alternative would cause an overall, system wide, cumulative reduction in GHG emissions from power plants that would be **somewhat greater than PSEGS**.

The Solar PV Alternative would not worsen current conditions or make a cumulatively considerable contribution to any significant cumulative impact associated with air quality.

Biological Resources

Solar PV technology would employ single-axis tracking PV technology at the proposed PSEGS site. It is assumed that the Solar PV Alternative would use a low-impact design that would minimize on-site grading and possibly entail management of native vegetation under the solar panels by mowing. It is possible that no grading would be necessary under most of the solar panels for the Solar PV Alternative, which is similar to the project owner's proposed vegetation management in the heliostat field for the PSEGS. Assuming the same project site boundary under this alternative, impacts on special-status plant species and waters of the state would be **similar to PSEGS**.

The PV Alternative would remove habitat occupied by desert tortoise and other special-status terrestrial wildlife species; this alternative would cause other direct and indirect impacts such as weed proliferation and increased dust. These impacts would be **similar to PSEGS**.

Impacts on avian species would occur through conversion of the project site from native habitat to a solar farm and potential collisions with project features such as PV panels and transmission lines. This technology does not require central collector towers (e.g., an SPT at the center of a heliostat array) or concentrate solar energy over a heliostat field; therefore, **no impacts** on avian species would occur from exposure to solar flux.

Little research-based data is available to determine the extent of collision impacts on avian species from either the PV or solar power tower technologies. Similar to concentrating solar power technology, the PV Alternative would have the potential to cause a *mirage* effect from the appearance of the sky reflected off the solar panels when viewed from a distance. Installation of heliostats could also cause an increase in polarized light pollution (PLP), which typically occurs from light reflecting off of dark colored anthropogenic structures, and has been demonstrated to be generated from even low-reflectance PV panels (Horváth et al. 2009). It is unknown to what extent this phenomenon is occurring or will occur from the surfaces of mirrored heliostats at newly developed SPT project sites (e.g., the ISEGS site). PLP caused by anthropogenic structures can alter the ability of wildlife to seek out suitable habitat and elude or detect the presence of predators (Horváth et al. 2010). It has also been documented that PLP can affect some organisms’ ability to detect natural polarized light patterns in the sky, which can negatively affect navigation ability and ultimately affect dispersal and reproduction (Horváth et al. 2009). Polarizing surfaces are also known to disrupt insect behavior, causing some insects to react as though the surface is water, and depositing eggs on polarizing surfaces (Horváth et al. 2009). The extent to which heliostats could serve as an attractant to avian species is unknown.

Reports of collisions are becoming more common as large-scale PV and concentrating SPT facilities are developed in the desert. Solar PV panels absorb rather than reflect solar energy. The reflective characteristics of the smooth, dark surfaces of PV panels are much different compared to the mirrored surfaces of the SPT heliostats that reflect the sun’s rays to the SRSGs. However, the glass surfaces of PV panels can and do reflect the sky. The reflective characteristics of PV panels likely vary depending on the position of the sun, viewing angle, tilt of the panels, and other variables (please see **Alternatives Figures 3a** and **Figure 3b** for representative photographs of PV arrays). PV solar arrays sometimes reflect the sky, including clouds, and can appear lighter in color. At other times and under different conditions, the PV arrays may appear dark like a still body of water. While it remains unclear how wildlife (primarily birds and bats, but also insects) perceive solar fields, and if the solar collectors are attractive under certain conditions, it is well documented that solar fields, including large PV array fields, can pose risks to birds or bats.

At the Desert Sunlight Solar Farm project site, a PV installation of a few thousand acres, birds have been documented to have collided with the panels or other project features (Pagel and Baird, pers. comms., 2013). The majority of the species impacted has been identified as migrant waterbirds that would not typically be found foraging in desert habitat, and whose presence would not have been expected to occur at the PV project site. A federally endangered species, the Yuma clapper rail (*Rallus longirostris yumanensis*), was among the recorded mortalities. Similarly, at the GSEP site, featuring reflective parabolic trough technology, waterbirds rarely found in the desert have collided with the mirrored troughs, or been found on-site, unable to fly, with no obvious injury. Both the GSEP and Desert Sunlight Solar Farm are in construction in Riverside County, between the Colorado River to the east and the proposed PSEGS site to the west. All three of these projects may be expected to encounter the same general suites of resident and migrant avian species. Of the injuries and mortalities that have occurred, reported incidents include birds being found overheated and/or stressed with no clear indication of the causes. Of the reported injuries or mortalities, some have occurred in association with evaporation ponds and as a result of collisions with perimeter fencing and other project features.

The extent and severity of potential collision impacts on avian species under the Solar PV Alternative is unquantifiable; however, given that collisions have been noted for various solar thermal collectors (e.g., parabolic troughs and heliostats) as well as PV panels, staff considers the potential risks of collisions or inducement to land on project site structures is likely **similar to PSEGS**. Impacts on avian species stemming from habitat loss could be mitigated to below a level of significance. For the Solar PV Alternative, impacts relating to collisions and other sources of injury or mortality associated with the facility could be significant. Staff recommends implementation of mitigation measures described in the **BIOLOGICAL RESOURCES** section of this staff assessment; however, a level of uncertainty exists as to the severity of the impact and the possible affected species. Staff considers these impacts on avian species to be significant, particularly if state or federally listed threatened, endangered, or other special-status species were impacted. Impacts could remain cumulatively significant after implementation of all feasible mitigation measures.

PV solar power plants require less operational water use, and less groundwater pumping, compared to the proposed modified project. Therefore, potential impacts on groundwater dependent plants and wildlife species would be **somewhat less than PSEGS**.

The PV alternative would use numerous individual driven foundation elements to support the PV panels, similar to PSEGS, and would eliminate the deep or otherwise specialized foundations required for the SPTs of the proposed modified project; however, the power towers would be located in a portion of the solar field that is outside of the active sand transport corridor. Because no specific single-axis tracking PV system is identified for this alternative, the number and diameter of the supporting piers for the PV modules is unknown compared to those required for the proposed PSEGS. Unlike the PSEGS project, the PV alternative would require fewer and smaller structures overall (no power towers, turbines, and steam condenser) and foundations. Assuming the same project footprint, direct impacts on the sand transport corridor, sand dunes, and Mojave fringe-toed lizard would likely be **somewhat less than PSEGS**. Without having a specific PV tracker technology identified for the project site, and in the absence of the modeling effort that would be needed to draw impact conclusions, staff is unable to make a comparative determination of the indirect impacts on sand transport corridors or for impacts on sand dunes and Mojave fringe-toed lizard.

Cultural Resources

Construction and operation of the Solar PV Alternative would require roughly the same extent of ground disturbance as the proposed PSEGS. The extent of the visual intrusion on cultural resources *beyond* the site compared to the proposed modified project would be **much less than PSEGS**, while the extent of physical disturbance of resources *on* the facility site compared to the proposed modified project would be **similar to PSEGS**.

The overall scale of the Solar PV Alternative and its vertical profile would be substantially less than PSEGS, given this alternative's lack of extremely tall structures that would be analogous in any way to the proposed PSEGS solar power towers. Compared to the approximately 750-foot-tall power towers and 12-foot vertical profile of the heliostat arrays of the proposed modified project, the vertical profile of the PV module arrays could be approximately 8 feet tall at maximum tilt. The PV arrays would be substantially less visible from most portions of the broad, landscape-scale resources that are the primary subjects of staff's concern; and where the terrain would allow views of portions of the PV arrays, the level of the visual intrusion in the landscape would be **much less than PSEGS**. In addition to the dramatically reduced vertical scale of the Solar PV Alternative, the lower reflectivity of the glass surfaces of the PV panels would be less intrusive compared to the mirrored heliostats. The overall physical disturbance of the portions of the cultural resources on the facility site, although minor relative to the overall size of landscape-scale resources, would nonetheless be roughly comparable to the degree of resource disturbance that would occur from the proposed modified project. Staff characterizes the net effect of this alternative on historical resources, primarily due to its much reduced visual presence relative to the proposed modified project, as **much less than PSEGS**.

Fire Protection

Construction-Related Impacts

Compared to the proposed PSEGS, construction of the Solar PV Alternative would require approximately the same level of service from the RCFD, and impacts on the RCFD would be approximately the same as the proposed PSEGS. Of the six RCFD services listed above (see the subsection, "Fire Protection, for the No-Project Alternative), construction of the Solar PV Alternative would require a much lower level of effort to conduct plan reviews, inspections, and permitting.

As described above for the comparison of impacts on fire protection under the "No-Project Alternative," hazardous materials use during construction activities and the impact on the RCFD relating to hazmat spill response would remain about the same for all alternatives compared to the proposed modified project.

Because the Solar PV Alternative does not include construction of extremely tall structures analogous to the 750-foot-tall SPTs of the proposed PSEGS, construction of this alternative would not have the added construction safety concern and the potential need to conduct a high-angle technical rescue in the event of worker injury. Under the Solar PV Alternative, no work in a confined space would be required during construction and little risk from fire would exist. Overall, construction-related direct and cumulative impacts on the RCFD under the Solar PV Alternative would be **much less than PSEGS**.

Project Operations Impacts

Solar PV technology, regardless of the type used, presents a far less need for the transportation, storage and use of hazardous materials than either solar parabolic trough or solar power tower technology and thus the need for hazardous materials spill response would be minimal. PV systems do not use steam generators because receiver units directly generate electricity and thus do not require the steam boilers, generators, steam condensers, and/or auxiliary heat rejection equipment associated with renewable solar thermal technologies. As a result, hazardous materials transportation, storage, and use would be minimal and workers exposure to spills would be **much less than PSEGS** for the Solar PV Alternative.

During operation of a PV facility, hazardous chemicals would be used and stored in relatively small amounts and represent limited risks of spills and need for response because of their small quantities, low volatility, and/or low toxicity. At the PSEGS site, several factors influence staff's conclusion that the risk of a release of hazardous materials would be extremely low:

1. Hazardous materials would very likely be delivered and stored in chemical "totes," which are designed to meet strict safety standards and thus have an excellent safety record of structural integrity and minimal spills.

2. Totes are self-contained units that do not involve the transfer of the hazardous material from a tanker truck to a large storage tank. They are delivered already containing the hazardous material.

3. The chance that more than one would fail at the same time is extremely remote.

4. The maximum volume of each tote is likely to be 400 gallons or less and each tote would be required to be placed within a secondary spill containment area to limit the spread of any spilled materials, thus limiting the size of the pool of material available for evaporation and dispersion.

5. Previous modeling at other power plants by staff of far greater amounts of various hazardous materials, including ammonia and sulfuric acid, spilling onto a road show very limited dispersion and the distance to a level of less than a significant airborne concentration is usually only a short distance. A spill into a containment area would have even a lesser dispersion distance.

However, solar PV panels present a unique safety hazard in that individual PV panels will continue to be energized and can generate electricity even when disconnected or covered unless the covering is composed of 100 percent light-blocking material. And, PV panels remain energized even when disconnected from the grid and during cloud cover. It is also estimated that at night, the light from facility light poles is powerful enough to re-energize a PV panel to a level that could present a shock hazard.

Therefore, even after disconnecting from the grid, PV panels are capable of discharging current to an object or a person. Standard regulations of the Occupational Safety and Health Administration requiring “Lockout/Tagout” of electrical systems are not sufficient to eliminate the threat posed by a PV panel or multiple panels to on-site workers, and consequently, impacts on rescue and EMS response. Emergency response personnel engaged in rescue or fire suppression are also at risk of coming into contact with electrified PV panels. This unique aspect of EMS and rescue response is not present with the other alternatives because once a circuit is cut (or locked-out) the current stops and workers are protected; this is the case for a project using parabolic trough technology or the SPT technology for the proposed PSEGS. For the Solar PV Alternative, the impact pertaining to the potential need for rescue services would be **somewhat less than PSEGS**.

Even with this added hazard to workers, staff concludes that the Solar PV Alternative would cause a lower impact on emergency services compared to the proposed PSEGS. Overall, impacts on emergency services during project operations for the Solar PV Alternative would be **much less than PSEGS**.

Geology and Paleontology

Primarily, the Solar PV Alternative would use numerous individual driven foundation elements to support the PV panels, similar to PSEGS, but would not require the deep or otherwise specialized foundations that would be required for the solar receiver towers of the proposed modified project. The elimination of deep foundations would decrease the potential for encountering fossil bearing strata; however, like the proposed modified project, impacts from the potential destruction of undiscovered paleontological resources would be a significant impact of this alternative.

Similar to the PSEGS project, solar PV panel foundation elements would be driven into the ground, potentially encountering and destroying buried fossils. Because no specific single-axis tracking PV system is identified for this alternative, the number and diameter of the supporting piers for the PV modules is unknown compared to those required for the proposed PSEGS.

Unlike the PSEGS project, the PV Alternative would require fewer and smaller structures (no towers, turbines, and steam condenser) and foundations required for support of these fewer and smaller structures would be similarly reduced. Therefore, construction of the Solar PV Alternative (driven panel post foundations coupled with decreased size and number of structure foundations) would cause impacts on paleontological resources that would be **somewhat less than PSEGS**.

The net effect to the Solar PV Alternative from geological hazards would be less than the PSEGS project. Due to elimination of tall tower structures, the project as a whole would have a decrease in seismic susceptibility. Potential impacts from strong seismic shaking would be **much less than PSEGS**. Potential impacts from soil failure mechanisms would also be **much less than PSEGS**.

Hazardous Materials Management

Construction-Related Impacts

As discussed above, the construction phases of any large-scale desert solar project would require the use of various hazardous materials posing similar on-site risks of spillage or other releases. For the Solar PV Alternative, construction-related hazardous materials impacts would be the **same as PSEGS**.

Project Operations Impacts

As discussed above under “Fire Protection,” solar PV technology presents a far less need for the transportation, storage, and use of hazardous materials than either solar parabolic trough or SPT technology. As a result, hazardous materials transportation, storage, and use would be **much less than PSEGS**.

During operation of a PV facility, hazardous chemicals such as cleaning agents, water treatment chemicals, welding gasses, oils, activated carbon, and other various chemicals would be used and stored in relatively small amounts and represent limited off-site hazards because of their small quantities, low volatility, and/or low toxicity. At the PSEGS site, several factors influence staff’s conclusion that the risk of off-site impacts from a release of hazardous materials would be extremely low:

1. Hazardous materials would very likely be delivered and stored in chemical “totes,” which are designed to meet strict safety standards and thus have an excellent safety record of structural integrity and minimal spills.

2. Totes are self-contained units that do not involve the transfer of the hazardous material from a tanker truck to a large storage tank. They are delivered already containing the hazardous material.

3. The chance that more than one would fail at the same time is extremely remote.

4. The maximum volume of each tote is likely to be 400 gallons or less, and each tote would be required to be placed within a secondary spill containment area to limit the spread of any spilled materials, thus limiting the size of the pool of material available for evaporation and dispersion.

5. Previous modeling at other power plants by staff of far greater amounts of various hazardous materials, including ammonia and sulfuric acid, spilling onto a road show very limited dispersion and the distance to a level of less than a significant airborne concentration is usually only a short distance. A spill into a containment area would have even a lesser dispersion distance.

6. The nearest off-site public receptors are 25 feet and 3,500 feet northwest of the PSEGS fence line and thus no matter where the small quantities of hazardous materials were placed on the site under this alternative, no off-site consequences would be expected if a spill was to occur.

Therefore, staff concludes that hazardous materials use for the Solar PV Alternative would pose a less than significant risk to the public and would be **much less than PSEGS**.

Land Use

The Solar PV Alternative would involve constructing and operating a utility-scale, single-axis tracking PV project at the proposed PSEGS site. The proposed PSEGS would be located entirely on public land administered by BLM and within the federal CDCA Plan area. The project area is in the “Multiple-Use Class M” land use category, which allows construction and operation of electrical generation plants. As discussed above, the PSEGS site is encompassed by BLM’s Riverside East SEZ. These designations also apply to the Solar PV Alternative. Like the proposed modified project, this alternative includes no private land, and no part of the site would be subject to Riverside County’s jurisdictional authority.

In February 2013, the project owner submitted a revised Plan of Development to BLM for the PSEGS. Should BLM approve issuance of a ROW grant for the PSEGS, two CDCA Plan amendments would be required—one would allow the solar generation facility and the other would allow the generation tie-line outside of the designated corridor (BLM 2013a). Staff recommends Condition of Certification **LAND-1** for the proposed PSEGS, which requires the project owner to provide documentation of the approved BLM ROW grant and a project-specific amendment to the CDCA Plan prior to the start of construction. **LAND-1** would also apply to the Solar PV Alternative. Like the proposed PSEGS, construction and operation of this alternative would require compliance with applicable federal land use LORS. Land use impacts of the Solar PV Alternative would be **similar to PSEGS**.

Public Health

Construction-Related Impacts

Construction-related combustion emissions and impacts would be similar to the proposed PSEGS for the Solar PV Alternative. Public health risks include diesel exhaust from diesel-fueled engines (such as trucks, graders, cranes, welding machines, electric generators, air compressors, and water pumps). According to staff’s analysis in the **PUBLIC HEALTH** section of this staff assessment, the calculated cancer risk and non-cancer Hazard Index from diesel particulate matter (DPM) are below the significance levels. Potential risks to public health during earth-moving construction activities would also be associated with exposure to Valley Fever in contaminated soil and fugitive dust disturbed during site preparation. As for the concerns of Valley Fever affecting the general population, staff considers the mitigation measures recommended in the **AIR QUALITY** section of this staff assessment adequate for the purposes of preventing all fugitive dust plumes from leaving the project boundary. As long as the dust plumes are kept within the project boundary, no significant risk would remain for Valley Fever to adversely affect the general population and public health. Therefore, no significant construction-related impacts on public health would occur, and no mitigation measures would be required. Much like the extent of site disturbance required for installation of the heliostats for the proposed PSEGS, construction of utility-scale single-axis tracking PV projects is being accomplished without extensive site grading. With the overall extent of site disturbance considered to be similar, public health impacts of the Solar PV Alternative would be **similar to PSEGS**.

Project Operations Impacts

The Solar PV Alternative would not cause minor combustion-related boiler emissions. Cooling towers and the equipment required for a traditional power plant would not be needed for the Solar PV Alternative. Infrequent washings of PV panels would be required. DPM emissions from the use of mobile sources (i.e., vehicle systems of mirror washing equipment and site support vehicles) for washing the PV panels would be less for the Solar PV Alternative compared to the proposed PSEGS. The heliostats that would be installed under the proposed modified project would require weekly washings with the potential for more frequent washings to be required. Based on staff's review of several sample utility-scale PV installations, washing of PV modules is required once or twice per year.

Some high-performance solar PV panel cells are known to contain small amounts of cadmium, selenium, and arsenic, and these substances could be emitted if any solar cells were broken during operation and maintenance activities. However, even with the possibility of PV panel cell breakage, staff does not consider any such emission hazards to be significant for public health and no mitigation measures would be required. Please refer to staff's "Waste Management" analysis (below) for more information on management and handling of PV panels. As described above, because this alternative would not cause emissions of toxic air contaminants from boiler combustion and cooling towers, staff considers the overall potential public health risks from the Solar PV Alternative to be **less than PSEGS**. The reduced frequency of washing the solar collectors (i.e., the PV panels compared to the heliostats of the proposed PSEGS) would reduce DPM emissions under this alternative.

Socioeconomics

For the Solar PV Alternative with Single-Axis Tracking Technology, the construction and operations workforce would likely be smaller and the phased construction schedule could be longer compared to the PSEGS. The construction schedule for a typical utility-scale PV project allows initial phases to be connected to the grid without the need for the entire project to be completed and operational. Also, the delivery of hundreds of thousands of PV panels for a utility-scale PV project could require multiple shipments of panels (Perez, pers. comm., 2013). Staff concludes in the **SOCIOECONOMICS** section of this staff assessment that construction and operation of the proposed PSEGS would not cause significant adverse direct or indirect socioeconomic impacts on public services. Even with the phased construction schedule that could increase the overall construction schedule by several months, the socioeconomic impacts of this alternative would be **similar to PSEGS**.

Construction and operation of this alternative would generate employment income and associated state and local sales taxes that would be similar to those for the proposed PSEGS. Like PSEGS, this alternative is on federal land; therefore, Section 17620 of the Education Code (school impact fees) would not apply and no property taxes would be paid. The economic benefits would **be similar to PSEGS**.

Soil and Water Resources

Solar PV systems do not use steam generators because receiver units (i.e., PV solar panels) directly generate electricity and thus do not require the steam boilers, generators, steam condensers, and/or auxiliary heat rejection equipment generally associated with a traditional power plant. As a result, characteristic impacts on water quality caused by the presence of power plant facilities would be **much less than PSEGS** for the Solar PV Alternative, namely the disposal of industrial wastewater and the risk of storm water exposure to industrial chemicals. Domestic sanitary waste would still need a septic system for proper disposal, and impacts relating to sanitary waste would be **similar to PSEGS**.

As discussed below under, “Waste Management,” depending on the type of PV module, use of PV panels could cause the release of hazardous CdTe waste if panels were damaged. The inadvertent discharge of hazardous waste during a large storm event would increase the potential for water quality impacts from storm damage to **somewhat greater than PSEGS**.

Much like the flow-through installation of heliostats, installation of the PV panels would not necessarily require significant site grading. Assuming that a single-axis tracking solar PV project with an electrical capacity similar to the proposed PSEGS could be constructed at the project site with no change to the site boundary, the potential for on-site/off-site flooding for the Solar PV Alternative would be **similar to PSEGS**. Impacts from 100-year flood flows (as shown on the FEMA maps) do not apply because the published maps show that the 100-year flood plain is not present at or near the proposed site.

Compared to the proposed PSEGS, the Solar PV Alternative would not require a temporary concrete batch plant for a solar tower or large foundations, or a temporary assembly building to construct heliostats. This alternative would not require the same level of construction activities needed to build traditional power plant facilities, which would result in less excavation, heavy equipment, personnel, and truck traffic compared to PSEGS. The Solar PV Alternative and the proposed PSEGS would need similar areas for construction laydown and temporary parking. Based on these factors, the impacts from the Solar PV Alternative relating to soil erosion during construction would be **somewhat less than PSEGS**.

Because of the decrease in frequency for washing of PV panels compared to what would be required to maintain the heliostats of PSEGS, this alternative would create less dust overall from washer vehicles driving on the dirt roads. Impacts relating to soil erosion during project operations would be **less than PSEGS**.

The Solar PV Alternative would require less water for project operations, given the less frequent washings required for PV solar panels. Operational water use is estimated to decrease by roughly 90 percent under the Solar PV Alternative (approximately 15 acre-feet per year [afy] compared to 201 afy). For purposes of impact analysis, it is assumed that any withdrawals exceeding the average natural recharge and exceeding a significant percentage of the total amount of groundwater in storage would cause a significant impact. Because the Chuckwalla Valley Groundwater Basin (CVGB) is estimated to have a positive groundwater balance by approximately 2,600 afy, neither PSEGS nor the Solar PV Alternative would result in basin overdraft. And although the difference in water use of the Solar PV Alternative over 30 years would be about 5,580 af less than PSEGS, total water use by the proposed PSEGS or this alternative would be very small compared to the CVGB's storage capacity of 15,000,000 af. Because the PSEGS or this alternative would reduce the amount of total stored groundwater by less than a tenth of 1 percent, potential impacts of the Solar PV Alternative on the CVGB and local well owners would be **somewhat less than PSEGS**.

Traffic and Transportation

Potential Damage to Roads

Staff reviewed four recently approved single-axis tracking solar photovoltaic facilities and found that construction of these projects required an average of 1.40 peak construction workers per MW of power generated, which is less than the 4.62 peak construction workers per MW required for the proposed PSEGS (BLM 2012, Kern County Planning and Community Development Department 2012, Merced County Planning and Community Development Department 2012, San Luis Obispo County Planning and Building Department 2011). The proposed PSEGS also would require 90 daily one-way truck trips during peak construction, which is considered by staff to be a fairly high number. Because the proposed PSEGS would involve more peak workers and truck trips, damage to roads near the project site would be **less than PSEGS** under the Solar PV Alternative with Single-Axis Tracking Technology. Mitigation measures similar to those recommended for the proposed modified project would reduce potential damage impacts on roadways to less than significant.

Level of Service on Roads and Highways – Construction

As discussed above, the Solar PV Alternative would likely generate less construction traffic than the proposed PSEGS; therefore, impacts on LOS would be **less than PSEGS**. Like the proposed modified project, implementation of appropriate mitigation measures (e.g., a traffic control plan) would reduce this impact to less than significant.

Level of Service on Roads and Highways – Operation/Post-Construction

The number of operations employees for the Solar PV Alternative with power output similar to the proposed PSEGS would likely be lower than the number of PSEGS operations employees. The solar PV projects reviewed by staff would require an average of 0.03 operations workers per MW generated, while the proposed PSEGS would have higher staffing levels at approximately 0.2 operations workers per MW generated. However, for all projects, the minimal number of trips generated by operations employees would have a negligible impact on traffic LOS. Therefore, impacts would be **similar to PSEGS**. No mitigation measures would be required.

Solar Collector Glint and Glare Impacts on Motorists and Pilots

In contrast to the PSEGS's heliostats (mirrors), solar PV panels absorb rather than reflect solar energy. Therefore, nuisance glint and glare impacts on motorists and pilots would be **much less than PSEGS**. Mitigation measures such as screening the site perimeter could be required to reduce any potential glint or glare impacts on motorists to less than significant. It is unlikely that any potential glint or glare from the solar panels would have any effect on pilots.

Solar Receiver Glare Impacts That Could be Hazardous to Motorists and Pilots

This alternative would not include glare-producing SRSGs and power towers, and as discussed earlier, PV panels absorb the vast majority of sunlight and do not have the same reflective characteristics as the mirrored heliostats. Also, the solar panels do not reflect any solar energy to heat a fluid circulating in a receiver. Therefore, the Solar PV Alternative would cause **no impact**.

Visual Resources

PV systems do not use steam generators because receiver units directly generate electricity and thus do not require the solar towers topped by solar receivers, steam boilers, generators, or steam condensers associated with the proposed PSEGS. This alternative would include solar arrays of PV modules (solar panels) at the PSEGS site with no change to the site boundary. The 230-kV transmission line from the project site to the Red Bluff Substation would use the same linear corridor as the proposed PSEGS.

Potential for Adverse Impacts on Scenic Vistas

Construction-Related Impacts: Construction of the PV Alternative would cause temporary visual impacts due to the presence of equipment, materials, and a workforce at the project site and along the transmission line route, an increase in visible traffic along I-10 and access roads, and large dust clouds generated by grading activities. The area of disturbance and construction period of this alternative would be generally similar to the proposed PSEGS project. As described above, the Solar PV Alternative would use numerous individual driven foundation elements to support the PV panels, similar to PSEGS, but would not require the deep or otherwise specialized foundations that would be required for the proposed modified project. Construction of power blocks and other large facilities under the proposed PSEGS would not be necessary under the PV

Alternative. The construction-related impacts of this alternative on scenic vistas would thus be **less than PSEGS**.

Project Operations Impacts: No designated scenic vistas were identified in the PSEGS study area, but panoramic and highly scenic vistas from the Palen McCoy Wilderness and Chuckwalla Mountains Wilderness would be affected by this alternative. The PV Alternative would not have two solar receivers with an extremely bright glare. Under this alternative, solar arrays of PV modules would be installed at the proposed PSEGS site that could appear similar to PSEGS in apparent extent and with similar industrial characteristics when viewed from the two Wilderness Areas. Blocks of single-axis PV tracker units have a lower vertical profile than solar-tower heliostats. For example, the SunPower T0 Tracker® units typically extend 5–6 feet above the ground and increase to approximately 8 feet at maximum tilt. The tops of the proposed PSEGS heliostat array fields would be approximately 12 feet tall. Although the overall site footprint would be comparable to the PSEGS, the vertical profile would be much lower and the intensity of the visual effect would likely be reduced compared to the proposed PSEGS. The potential for this alternative to substantially degrade the existing visual character or quality of the site and its surroundings would be **less than PSEGS**. However, like the proposed PSEGS, this impact would remain significant and unavoidable under the Solar PV Alternative.

The visual characteristics of the affected project area would differ compared to the proposed PSEGS. Under the proposed PSEGS, the mirror field would exhibit diffuse and direct reflections (*lake-surface* effects). The PV units would also exhibit sky reflection, but would be much less bright, presenting a darker-colored appearance much of the time. In addition, PV projects would not require large-scale power block facilities like those required for solar thermal technologies. Because of the overall lower height of the array fields, lower reflectivity of the solar collectors, and lack of power blocks, the Solar PV Alternative would be less visible from viewpoints at distances of at least a few miles compared to the previously approved PSPP. Finally, the PV Alternative would not include solar towers and SRSGs. Consequently, the impact on scenic vistas would be **much less than PSEGS**. This alternative would be visible from both Wilderness Areas and the introduction of an expansive area with industrial characteristics and strong color and texture contrast would likely result in substantial adverse effects on these elevated vistas. The impact on scenic vistas would remain significant and unavoidable.

Potential to Substantially Damage Scenic Resources within a State Scenic Highway

The PSEGS site is located adjacent to the north side of I-10, which is not listed as an eligible State Scenic Highway, and no notable scenic features or historic structures are located within the site. Therefore, construction of the PV Alternative would not substantially damage scenic resources within a state scenic highway. This impact would be **similar to PSEGS**. Project operations impacts of the PV Alternative on scenic resources within a state scenic highway would be **similar to PSEGS**.

Potential to Substantially Degrade the Existing Visual Character or Quality of the Site and its Surroundings

Construction-Related Impacts: As discussed above, the area of disturbance and construction period of the PV Alternative would generally be similar to the proposed PSEGS project. Both PV tracker arrays and solar tower heliostats would be installed using numerous individual driven foundations. Construction impacts of this alternative on visual quality would be **similar to PSEGS**.

Project Operations Impacts: The PV Alternative would involve installation of an expanse of structures with industrial characteristics into the views from I-10, Corn Springs Road, and nearby Wilderness Areas. However, because of this alternative's lower profile and lack of tall or highly-reflective features, the PV Alternative would have a less intense visual effect compared to the proposed PSEGS, and would have a much smaller overall area of visual effect. It is likely that visual effects on SR 177, Desert Center, and Joshua Tree National Park would be negligible due to distance (approximately 10 miles or more from the project site). The impact of the PV Alternative on visual quality would thus be **less than PSEGS**. However, this alternative would result in a substantial degradation of the existing visual character or quality of the site and its surroundings as viewed from elevated viewpoints within nearby Wilderness Areas.

Potential to Create a New Source of Substantial Light or Glare Which Would Adversely Affect Day or Nighttime Views in the Area

Construction-Related Impacts: Some construction activity could take place at night during construction of the Solar PV Alternative, with lighting impacts that would be **similar to PSEGS**.

Project Operations Impacts: Non-mirror surfaces of the solar modules of the PV Alternative have the potential to introduce reflected glare into the visual environment. However, the PV Alternative would not require power blocks and the large, prominent structures of traditional power plant facilities. This impact would thus be **much less than PSEGS**. Like the proposed modified project, with the effective implementation of Condition of Certification **VIS-1** from the PSPP 2010 Commission Decision, the PV Alternative would not cause excessive glare from surfaces of structures other than the PV modules (e.g., inverters in the array blocks, O&M facilities, perimeter fencing, etc.).

Glint effects, that is, inadvertent, very bright reflections of the sun's image off the solar panels under certain conditions, could present a disruptive visual distraction for motorists and other viewers under some circumstances. However, these reflections would be much less bright and intrusive than similar glint effects from mirrored surfaces of the PSEGS heliostats due to the much lower reflectivity of PV panel surfaces compared to mirrors. This glint impact would be **much less than PSEGS**.

Compared to the proposed PSEGS, the Solar PV Alternative would not include anything analogous to the solar towers with solar receivers, and would not generate strong SRSG glare that would be similar in any way to the proposed PSEGS. The impact of the PV Alternative relating to glare from solar receivers would not occur; therefore, **no impact** would occur compared to PSEGS.

The PV Alternative could generate nighttime light pollution from its operational lighting, although with far fewer large or high-profile power plant structures, this impact would likely be **less than PSEGS**. As with the proposed modified project, the effective implementation of Condition of Certification **VIS-4** (VIS-3 from the 2010 Commission Decision on the PSPP) would reduce the PV Alternative's off-site, project operations lighting impacts to less than significant.

The PV Alternative would not have solar towers that would require FAA safety lighting, and **no impact** would occur.

Waste Management

Construction and operation of the Solar PV Alternative at the PSEGS site could have impacts **similar to PSEGS**. PV modules can be made of silicon or CdTe. Broken or damaged silicon PV modules are not considered hazardous, and would be similar to the heliostat materials. Broken or damaged CdTe PV modules would likely be transported to the manufacturer for recycling as universal waste and not be considered hazardous waste requiring landfill disposal.

Potential impacts relating to soil and water contamination and the potential presence of UXO at the site would be **similar to PSEGS**. A UXO Identification, Training, and Reporting Plan would still be required, which would include site worker training and procedures for UXO investigation, removal, and disposal.

REDUCED ACREAGE ALTERNATIVE WITH SOLAR POWER TOWER TECHNOLOGY

Overview

The Reduced Acreage Alternative with SPT Technology would involve reducing the total project acreage of the proposed modified project and retaining the solar tower unit and heliostat array from PSEGS Unit 1 (the western solar field). **Alternatives Figures 5a** and **5b** show staff's concept for the Reduced Acreage Alternative. The technology for the Reduced Acreage Alternative would be the same as described for the proposed PSEGS. This alternative includes approximately 70 acres from PSEGS Unit 2 (the eastern solar field). The additional acreage would allow a small expansion of the Unit 1 solar field while avoiding an extensive area of desert dry wash woodland habitat in the PSEGS eastern solar field (**Alternatives Figure 5a**). This alternative would avoid a portion of the sand transport corridor that extends into the northeast portion of the proposed PSEGS solar fields (**Alternatives Figure 5b**).

With the addition of acreage from Unit 2, the solar field area for the Reduced Acreage Alternative would cover approximately 1,742 acres. The adjacent 218-acre common area and construction lay down area adjacent to PSEGS Unit 1 would be retained. Like the proposed PSEGS, the generation tie-line would connect at the north side of the heliostat array field. The proposed natural gas pipeline would require rerouting for this alternative.

Potential to Attain Project Objectives

Development of an approximately 250-MW SPT project at the proposed PSEGS site could partially satisfy the project objectives to construct and operate a utility-scale solar energy project and assist SCE in satisfying its RPS program goals; however, the total proposed 500-MW capacity would not be achieved. This alternative could potentially satisfy the project objective to develop a solar thermal power plant at a site where some authorizations for construction have been obtained, although the licensed site would not be fully used to produce renewable energy. This alternative does not propose another use for the remainder of the site (the eastern solar field) should it not be developed for the proposed PSEGS. This alternative would satisfy the project objective to develop a site that is in a BLM-designated SEZ.

The Reduced Acreage Alternative with SPT Technology would likely satisfy the project objective to meet permitting requirements and comply with applicable LORS. This alternative would satisfy the project objective to develop a renewable energy facility in an area with high solar value and minimal slope.

Environmental impacts on some resources would be reduced under this alternative compared to the proposed modified project, particularly when there is a direct correlation between project acreage and the extent of the impact. This alternative could meet the project objective to avoid or minimize significant impacts to the greatest extent feasible. See the discussions below under, “Environmental Analysis,” for general analyses of the environmental effects of this alternative compared to the proposed modified project, including an analysis of comparative biological resources impacts.

The Reduced Acreage Alternative with SPT Technology could potentially satisfy many of the project objectives, although the total energy capacity would be reduced.

Potential Feasibility Issues

Staff presumes that the two solar plants under the proposed modified project are each the subject of one of the approved PPAs. If the total electrical capacity was reduced to approximately 250 MWs under the Reduced Acreage Alternative with SPT Technology, it is unknown whether an amendment to either of the approved PPAs by CPUC would be required. Reducing the project’s electrical capacity by approximately one-half would presumably affect the project owner’s LGIA with CAISO, which is for 500 MWs of interconnection rights. It is not known the extent to which eliminating most of the eastern solar field from the PSEGS site would affect the project schedule, although it is assumed that a schedule delay could affect project viability for the one 250-MW project.

As stated above, BLM is considering the project owner's ROW application and revised POD for the PSEGS and has published a draft SEIS for the project (BLM 2013a). Changing the project to reduce one of the 250-MW projects could require revising the POD for resubmittal to BLM, which would also delay the schedule.

Environmental Analysis

Alternatives Table 5 presents a summary comparison of impacts of the proposed modified project to the same or similar potential impacts of the Reduced Acreage Alternative with SPT Technology. Comparative discussions for each environmental topic area follow the table.

Alternatives Table 5
Summary Comparison of Impacts of the Proposed PSEGS to the Reduced Acreage Alternative with SPT Technology

Environmental Effect	Proposed PSEGS	Reduced Acreage Alternative with SPT Technology
Air Quality		
Construction-related emissions	SM (locally)	Somewhat less than PSEGS (SM)
Project operations emissions	SM (locally)	Similar to PSEGS (SM)
Reduction in greenhouse gases	B (system wide)	Similar to PSEGS (B)
Biological Resources		
Impacts on special-status plant species	SM	Much less than PSEGS (SM)
Impacts on waters of the state	SM	Much less than PSEGS (SM)
Impacts on desert tortoise	SM	Much less than PSEGS (SM)
Impacts on special-status terrestrial wildlife species (kit fox, American badger)	SM	Much less than PSEGS (SM)
Potential impacts on avian species from collisions with project features	PSU	Less than PSEGS (PSU)
Potential impacts on avian species from exposure to concentrated solar flux	PSU	Less than PSEGS (PSU)
Potential impacts on groundwater dependent ecosystems	SM	Somewhat less than PSEGS (SM)
Impacts on sand transport corridor	SM	Less than PSEGS (SM) *(see biological resources note)*
Impacts on sand dunes and Mojave fringe-toed lizard	SM	Less than PSEGS (SM) *(see biological resources note)*
Biological resources note: Comparative impacts for the Reduced Acreage Alternative for indirect impacts on the sand transport corridor, sand dune habitat, and Mojave fringe-toed lizard cannot reasonably be characterized without further data and use of a sand transport model.		

Alternatives Table 5
Summary Comparison of Impacts of the Proposed PSEGS to the Reduced Acreage Alternative with SPT Technology

Environmental Effect	Proposed PSEGS	Reduced Acreage Alternative with SPT Technology
Cultural Resources		
Potential to substantively degrade, directly or indirectly, prehistoric or historical archaeological resources *on* the facility site, resources recommended or assumed to be historically significant *(see cultural resources note)*	PSM	Less than PSEGS (PSM)
Potential to substantively degrade, directly or indirectly, prehistoric or historical archaeological resources *beyond* the facility site, resources recommended or assumed to be historically significant	SU	Similar to PSEGS (SU)
Potential for cumulatively considerable degradation of prehistoric or historical archaeological resources *beyond* the facility site, resources recommended or assumed to be historically significant	SU	Similar to PSEGS (SU)
Potential impacts on significant built-environment cultural resources *on* the site	LS	Similar to PSEGS (LS)
Potential impacts on a significant built-environment cultural resource (Desert Center) *beyond* the site	SU	Similar to PSEGS (SU)
Potential to substantively degrade, directly or indirectly, ethnographic resources *on* the facility site, resources recommended or assumed to be historically significant	PSM	Similar to PSEGS (PSM)
Potential for cumulatively considerable degradation of ethnographic resources *on* the facility site, resources recommended or assumed to be historically significant	LS	Similar to PSEGS (LS)
Potential to substantively degrade, directly or indirectly, ethnographic resources *beyond* the facility site, resources recommended or assumed to be historically significant	SU	Similar to PSEGS (SU)
Potential for cumulatively considerable degradation of ethnographic resources *beyond* the facility site, resources recommended or assumed to be historically significant	SU	Similar to PSEGS (SU)
Cultural resources note: "Site" means the facility site proper and does not include linear or ancillary infrastructure away from the facility site.		
Fire Protection		
Construction-Related Impacts		
Impacts on the Riverside County Fire Department	SM	Same as PSEGS (SM)
Project Operations Impacts		
Become familiar with and plan for emergency responses	SM	Same as PSEGS (SM)
Conduct plan reviews, inspections, and permitting	SM	Same as PSEGS (SM)
Fire response	SM	Same as PSEGS (SM)
Hazardous materials spill response	SM	Same as PSEGS (SM)
Rescue	SM	Same as PSEGS (SM)
Emergency medical services	SM	Same as PSEGS (SM)
Geology and Paleontology		
Potential impacts from strong seismic shaking	SM	Somewhat less than PSEGS (SM)
Potential impacts from soil failure caused by liquefaction, hydrocollapse, and/or dynamic compaction	SM	Somewhat less than PSEGS (SM)

Alternatives Table 5
Summary Comparison of Impacts of the Proposed PSEGS to the Reduced Acreage Alternative with SPT Technology

Environmental Effect	Proposed PSEGS	Reduced Acreage Alternative with SPT Technology
Potential impacts on paleontological resources	SM	Less than PSEGS (SM)
Potential impacts on geological or mineralogical resources	—	—
Hazardous Materials Management		
Construction-Related Impacts		
Potential for spills or other releases of hazardous materials to occur on-site	SM	Same as PSEGS (SM)
Potential for spills or other releases of hazardous materials to occur off-site	LS	Same as PSEGS (LS)
Project Operations Impacts		
Potential for spills or other releases of hazardous materials to occur on-site	SM	Same as PSEGS (SM)
Potential for spills or other releases of hazardous materials to occur off-site	LS	Same as PSEGS (LS)
Land Use		
Compatibility with land use plan, policy, or regulation	SM	Similar to PSEGS (SM)
Public Health		
Potential for project construction to cause air toxics-related or other impacts that could affect public health	LS	Less than PSEGS (LS)
Potential for project operations to cause air toxics-related or other impacts that could affect public health	PSM	Less than PSEGS (PSM)
Socioeconomics		
Environmental justice population within 6-mile buffer.	—	—
Induce substantial population growth in an area, either directly or indirectly.	LS	Somewhat less than PSEGS (LS)
Displace substantial numbers of people and/or existing housing, necessitating the construction of replacement housing elsewhere.	LS	Somewhat less than PSEGS (LS)
Adversely impact acceptable levels of service for police protection, schools, and parks and recreation.	LS	Somewhat less than PSEGS (LS)
Increased property taxes, construction and operation employment income, and increased state and local taxes and fees.	B	Somewhat less than PSEGS (B)
Soil and Water Resources		
Soil erosion by wind and water during project construction	SM	Less than PSEGS (SM)
Soil erosion by wind and water during project operations	PSM	Less than PSEGS (PSM)
Water quality impacts from contaminated storm water runoff	SM	Less than PSEGS (SM)
Water quality impacts from storm damage	PSM	Less than PSEGS (PSM)
Water quality impacts from power plant operations	SM	Less than PSEGS (SM)
Water quality impacts from sanitary waste	SM	Somewhat less than PSEGS (SM)

Alternatives Table 5
Summary Comparison of Impacts of the Proposed PSEGS to the Reduced Acreage Alternative with SPT Technology

Environmental Effect	Proposed PSEGS	Reduced Acreage Alternative with SPT Technology
Potential impacts from on-site and off-site flooding	PSM	Less than PSEGS (PSM)
Potential to impede or redirect 100-year flood flows, as shown on Federal Emergency Management Agency maps	—	—
Potential impacts on local wells	PSM	Somewhat less than PSEGS (PSM)
Potential impacts on groundwater basin balance	PSM	Somewhat less than PSEGS (PSM)
Traffic and Transportation		
Potential damage to roads	PSM	Somewhat less than PSEGS (PSM)
Level of service on roads and highways – construction	PSM	Less than PSEGS (PSM)
Level of service on roads and highways – operation/post-construction	LS	Similar to PSEGS (LS)
Solar collector glint and glare impacts on motorists and pilots	PSM	Less than PSEGS (PSM)
Solar receiver glare impacts that could be hazardous to motorists and pilots	PSM	Somewhat less than PSEGS (PSM)
Visual Resources		
Construction-Related Impacts		
Potential for adverse impacts on scenic vistas	SM	Less than PSEGS (SM)
Potential to substantially damage scenic resources within a state scenic highway	LS	Similar to PSEGS (LS)
Potential to substantially degrade the existing visual character or quality of the site and its surroundings	SM	Less than PSEGS (SM)
Potential to create a new source of substantial light or glare which would adversely affect day or nighttime views in the area	SM	Less than PSEGS (SM)
Project Operations Impacts		
Potential for adverse impacts on scenic vistas	SU	Somewhat less than PSEGS (SU)
Potential to substantially damage scenic resources within a state scenic highway	LS	Similar to PSEGS (LS)
Potential to substantially degrade the existing visual character or quality of the site and its surroundings	SU	Somewhat less than PSEGS (SU)
Potential to create a new source of substantial light or glare which would adversely affect day or nighttime views in the area (individual effects listed below)		
Glint or glare effects from project structures other than the reflective surfaces of solar collectors (i.e., heliostats, parabolic troughs, PV panels)	SM	Similar to PSEGS (SM)
Glint or glare effects from the solar collectors	SM	Similar to PSEGS (SM)
Glint or glare effects from high-profile solar receiver steam generators	SU	Somewhat less than PSEGS (SU)
Light or glare from nighttime lighting effects, including Federal Aviation Administration safety lighting	SM	Somewhat less than PSEGS (SM)

Alternatives Table 5
Summary Comparison of Impacts of the Proposed PSEGS to the Reduced Acreage Alternative with SPT Technology

Environmental Effect	Proposed PSEGS	Reduced Acreage Alternative with SPT Technology
Waste Management		
Potential for unexploded ordnance to be present at the project site	PSM	Similar to or less than PSEGS (PSM)
Potential for impacts on human health and the environment relating to past or present soil or water contamination	LS	Similar to or less than PSEGS (LS)
Potential for impacts on human health and the environment relating to potential waste discharges	LS	Similar to or less than PSEGS (LS)
Potential for disposal or diversion of project materials to cause impacts on existing waste disposal or diversion facilities	LS	Less than PSEGS (LS)

Air Quality

Exhaust emissions from heavy-duty diesel construction equipment and fugitive particulate matter (dust) emissions would be approximately half the emissions of the proposed modified project due to the reduced number of heliostats and one less power tower. Exhaust emissions would also be caused by workers commuting to and from the work sites, trucks hauling equipment and supplies to the sites, and crew trucks (e.g., derrick trucks, bucket trucks, pickups). With this alternative, the number of workers commuting would be reduced and the duration of the construction during which the workers would be commuting would be reduced by approximately one-half. Exhaust emissions from the worker and delivery vehicles would be half those of the proposed modified project. The total area of site disturbance would be approximately half that of the proposed PSEGS, and emissions of particulate matter during construction would be less than PSEGS; however, the comparative reduction in particulate matter would likely be negligible. The construction emissions of this alternative would be **somewhat less than PSEGS**. No decrease in construction-related emissions would occur with construction of the generation tie-line, which would remain the same length as with the proposed modified project.

The operational emissions from the Reduced Acreage Alternative with SPT Technology would be **similar to PSEGS**. Appropriate mitigation measures for the Reduced Acreage Alternative with SPT Technology would likely involve similar, locally-oriented recommendations such as the conditions of certification presented in the **Air Quality** section of this staff assessment. It is likely that the alternative would comply with the South Coast Air Quality Management District rules and regulations.

The Reduced Acreage Alternative with SPT Technology would produce about half less energy than the proposed PSEGS. As with the proposed 500-MW project, a 250-MW project would cause some GHG emissions. However, the 250-MW project would help meet the RPS program goals in California and would result in a net cumulative reduction of energy generation and GHG emissions from new and existing fossil fuel-fired electricity resources. These system impacts would result in a net reduction in GHG emissions across the electricity system providing energy and capacity to California. Thus, as with the proposed PSEGS, the Reduced Acreage Alternative with SPT Technology would result in a cumulative overall reduction in GHG emissions from power plants; because this alternative would require the use of auxiliary equipment necessary to operate a solar thermal power plant, the effect of reducing GHG emissions would be **similar to PSEGS**.

Biological Resources

This alternative would reduce the total project acreage to approximately 1,960 acres, which includes the 218-acre common area/construction laydown area. This alternative was developed by retaining the solar tower unit and heliostat array from PSEGS Unit 1 (the western solar field), and would include approximately 70 acres from PSEGS Unit 2 (the eastern solar plant). A total of three special-status plant species are known to be located on the proposed modified project site, and would require mitigation to reduce the impacts to less than significant. The three plant species are ribbed cryptantha (*Cryptantha costata*), Harwood's milkvetch (*Astragalus insularis var. harwoodii*), and California ditaxis (*Ditaxis serrata var. californica*). This alternative would avoid all impacts on mapped populations of ribbed cryptantha, and eliminate impacts on one mapped population of Harwood's milkvetch. Impacts on California ditaxis would be unchanged, as they occur along the generation tie-line. The Reduced Acreage Alternative would therefore reduce impacts on two rare plant species identified at the project site, and these impacts would be **much less than PSEGS**.

Jurisdictional waters of the state enter the project site from the south, fanning out across the alluvium. The Reduced Acreage Alternative would reduce impacts on on-site vegetation, including waters of the state, desert dry wash woodland, and unvegetated ephemeral dry washes. Impacts on these habitats of special concern would be **much less than PSEGS**. This alternative would also cause direct impacts on aeolian sand corridors Zone II and Zone III that would be **less than PSEGS**, although staff notes that indirect effects would be described only through modeling, an exercise that was not conducted for this alternatives analysis. This analysis describes only direct impacts. Impacts on Mojave fringe-toed lizard would also likely be **less than PSEGS**; however, uncertainty exists in the degree to which impacts would be reduced. Mojave fringe-toed lizard inhabit dune habitat, and therefore, a full description of direct and indirect effects on the sand transport corridor would be necessary for staff to complete an analysis of effects on Mojave fringe-toed lizard and sand dune habitat.

Terrestrial wildlife on the site vary from the highly mobile kit fox and American badger, to the relatively stationary desert tortoise. Surveys for these species were conducted in 2009, 2010, and 2013 during surveys for the generation tie-line. Elimination of the Unit 2 (eastern) power tower and heliostat field would likely reduce impacts on kit fox, desert tortoise, and American badger foraging habitat and burrows or burrow complexes. The burrowing owl, a state species of special concern, has been documented within the Unit 2 area, but not the Unit 1 area. Given that several years have passed since on-site surveys for burrowing owl were conducted, staff is unclear as to the current distribution and population of burrowing owl on-site, but regardless, the Reduced Acreage Alternative would reduce impacts on habitat that is suitable for burrowing owl, and therefore, impacts on this species under this alternative would be **much less than PSEGS**.

The Reduced Acreage Alternative would eliminate one solar power tower and its associated heliostat field. Similar to the proposed modified project, the structures associated with this alternative could attract birds. It is unknown the extent to which eliminating one solar field would reduce the potential for collisions with project features. By the same reasoning, it is unknown the extent to which eliminating one solar field would reduce the potential for exposure to concentrated solar flux. Staff concludes that impacts on avian species would be **less than PSEGS**, to an unquantifiable degree, with elimination of one of the two solar fields. Potential impacts on the groundwater basin would be somewhat less than PSEGS (see the subsection below, “Soil and Water Resources”); therefore, the impacts on groundwater dependent vegetation and associated plant and wildlife species would also be **somewhat less than PSEGS**.

Cultural Resources

Construction and operation of the Reduced Acreage Alternative would reduce the extent of ground disturbance at the project site. Because the overall vertical profile of the Reduced Acreage Alternative compared to the proposed PSEGS would remain essentially the same, this alternative would produce a similar level of visual intrusion on resources *beyond* the facility site. Staff characterizes the net effect of this alternative on historical resources as **similar to PSEGS**.

Fire Protection

Construction-Related Impacts

Compared to the proposed PSEGS, construction of the Reduced Acreage Alternative with SPT Technology would require approximately the same level of service from the RCFD, and impacts on the RCFD would be approximately the **same as PSEGS**.

Project Operations Impacts

Fire protection associated with the Reduced Acreage Alternative with SPT Technology would essentially be the **same as PSEGS**. While there would be lower volumes of hazardous materials on the site and one less power tower and its power block and solar field, and thus less of a need for hazardous materials spill and rescue response, the differences would result in negligible differences in impacts.

Geology and Paleontology

The Reduced Acreage Alternative with SPT Technology would reduce the total project acreage of the proposed modified project and involve building the solar tower unit and heliostat array for PSEGS Unit 1 (the western solar field).

Because the ground disturbance from the Reduced Acreage Alternative would be approximately one-half of that associated with the proposed PSEGS, potential impacts on paleontological resources would be correspondingly reduced and are considered **less than PSEGS**. Because one less SPT would be erected on the site, potential impacts on the facility from geologic hazards (i.e., impacts from strong seismic shaking) would be **somewhat less than PSEGS**. No changes to the proposed mitigation measures would be required.

Hazardous Materials Management

Construction-Related Impacts

As discussed above, the construction phases of any large-scale desert solar project would require the use of various hazardous materials posing similar on-site risks of spillage or other releases. For the Reduced Acreage Alternative with SPT Technology, construction-related hazardous materials impacts would be **similar to PSEGS**.

Project Operations Impacts

Hazardous materials use associated with the Reduced Acreage Alternative with SPT Technology would be essentially the **same as PSEGS**. While there would be lower volumes of hazardous materials on the site due to the elimination of one power tower and its power block and solar field, the differences would result in negligible differences in impacts.

Land Use

The Reduced Acreage Alternative with SPT Technology would reduce the total project acreage to approximately 1,960 acres and retain the solar tower unit and heliostat array from PSEGS Unit 1 (the western solar field). The technology for this alternative would be the same as described for the proposed PSEGS. The Reduced Acreage Alternative would provide benefits compared to the proposed PSEGS (e.g., reduced impacts on terrestrial species and habitats).

The project area is in BLM's "Multiple-Use Class M" land use category, which allows construction and operation of electrical generation plants. The PSEGS site is encompassed by BLM's Riverside East SEZ. These designations also apply to the Reduced Acreage Alternative. Like the proposed modified project, this alternative includes no private land, and no part of the site would be subject to Riverside County's jurisdictional authority.

Should BLM approve issuance of a ROW grant for the PSEGS, two CDCA Plan amendments would be required—one would allow the solar generation facility and the other would allow the generation tie-line outside of the designated corridor (BLM 2013a). Staff recommends Condition of Certification **LAND-1** for the proposed PSEGS, which requires the project owner to provide documentation of the approved BLM ROW grant and a project-specific amendment to the CDCA Plan prior to the start of construction. **LAND-1** would also apply to the Reduced Acreage Alternative. Like the proposed PSEGS, construction and operation of this alternative would require compliance with applicable federal land use LORS. Land use impacts of the Reduced Acreage Alternative would be **similar to PSEGS**.

Public Health

Construction-Related Impacts

Since the technologies are the same for both the Reduced Acreage Alternative with SPT Technology and the proposed PSEGS, construction-related emissions and impacts would be the same. However, the amounts of construction-related emissions and impacts of this alternative would be approximately half that of the proposed PSEGS since the project footprint would be decreased from approximately 3,794 acres to approximately 1,742 acres (not including the 218-acre common area/construction laydown area). Public health impacts for this alternative would be **less than PSEGS**. Like the proposed PSEGS, no significant impacts would occur, and no mitigation measures would be required for construction-related emissions.

Project Operations Impacts

Since the technologies are the same for both the Reduced Acreage Alternative with SPT Technology and the proposed PSEGS, project operations emissions would be the same per unit of capacity. However, the amounts of emissions and impacts from operation of this alternative would be approximately half that of the proposed PSEGS due to the reduced number of boilers and extent of mirror washing. For the Reduced Acreage Alternative with SPT Technology, the potential for exposure to *Legionella* would remain with operation of the WSAC units at Power Block 1 of the western solar field. For PSEGS, the impact is reduced to less than significant with implementation of Condition of Certification **PUBLIC HEALTH-1**. The same mitigation measure would apply to this alternative. Overall, the operational emissions from the Reduced Acreage Alternative with SPT Technology would be **less than PSEGS**.

Socioeconomics

This alternative proposes one solar power tower, compared with the two solar power towers proposed for PSEGS. Staff concludes in the **SOCIOECONOMICS** section of this staff assessment that construction and operation of the PSEGS would not cause significant adverse direct or indirect socioeconomic impacts on public services.

With the reduction of the equipment installed for this alternative, the workforce for project construction and operations would be smaller overall and the duration of construction would be shorter. Given the smaller construction and operations workforces required and shorter construction schedule, the socioeconomic impacts for this alternative would be **somewhat less than PSEGS**.

Construction and project operation of this alternative would generate employment income and associated state and local sales taxes that would be somewhat less than the PSEGS. Like PSEGS, this alternative is on federal land; therefore, Section 17620 of the Education Code (school impact fees) would not apply and no property taxes would be paid. The economic benefits of this alternative would be **somewhat less than PSEGS**.

Soil and Water Resources

The Reduced Acreage Alternative with SPT Technology would involve reducing the total project site acreage and effectively only building the solar tower unit and heliostat array for PSEGS Unit 1 (the western solar field).

Because the footprint for the Reduced Acreage Alternative would decrease to roughly half that of PSEGS, impacts relating to soil erosion during construction (grading of roadways and power plant construction) and operations (heliostat washing and vegetation maintenance) would be **less than PSEGS**. Operation of one power plant compared to two would decrease the volume of process wastewater and contamination of storm water runoff; therefore, these impacts would be **less than PSEGS**. The amount of domestic sanitary waste disposed in septic systems would decrease, so these impacts would be **somewhat less than PSEGS**.

Because at least half of off-site flows pass through PSEGS Solar Unit 1, impacts from flood flows and flooding for the Reduced Acreage Alternative would be **less than PSEGS**. Also, by avoiding storm damage impacts in the Solar Unit 2 solar field, the overall impacts of storm water damage for the Reduced Acreage Alternative would be **less than PSEGS**. Impacts from 100-year flood flows (as shown on FEMA maps) do not apply because the published maps show that the 100-year flood plain is not present at or near the proposed site.

The Reduced Acreage Alternative would require less operational water use for process and heliostat washing compared to the proposed PSEGS. Assuming installation of approximately half the total number of heliostats compared to PSEGS, operational water use could be reduced up to half of the total amount under this alternative. For purposes of impact analysis, it is assumed that any withdrawals exceeding the average natural recharge and exceeding a significant percentage of the total amount of groundwater in storage would cause a significant impact. Because the Chuckwalla Valley Groundwater Basin (CVGB) is estimated to have a positive groundwater balance by approximately 2,600 afy, neither PSEGS nor the Reduced Acreage Alternative would result in basin overdraft. And although the difference in water use for this alternative would be about 3,580 af less than PSEGS, total water use by the proposed PSEGS or this alternative would be very small compared to the CVGB's storage capacity of 15,000,000 af. Because the PSEGS or this alternative would reduce the amount of total stored groundwater by less than a tenth of 1 percent, potential impacts of the Reduced Acreage Alternative on the CVGB and local well owners would generally be **somewhat less than PSEGS**.

Traffic and Transportation

Potential Damage to Roads

This alternative would result in a smaller project to develop, and therefore fewer construction workers and a shorter construction period. However, heavy haul trucks that could damage roads would be used for both this alternative and the proposed PSEGS. For these reasons, road damage would be **somewhat less than PSEGS**. Mitigation measures similar to those recommended for the proposed modified project would reduce potential damage impacts on roadways to less than significant.

Level of Service on Roads and Highways – Construction

This alternative would result in a smaller project to develop, and therefore fewer construction workers and a shorter construction period. For these reasons, impacts on LOS would be **less than PSEGS**. Like the proposed modified project, implementation of appropriate mitigation measures (e.g., a traffic control plan) would reduce this impact to less than significant.

Level of Service on Roads and Highways – Operation/Post-Construction

The Reduced Acreage Alternative would be smaller than the proposed PSEGS and would probably require fewer employees to operate. However, for both the Reduced Acreage Alternative and the proposed PSEGS, the minimal number of trips generated by operations employees would have a negligible impact on traffic LOS. Therefore, impacts would be **similar to PSEGS**. No mitigation measures would be required.

Solar Collector Glint and Glare Impacts on Motorists and Pilots

This alternative would involve installation of approximately half the number of heliostats required for the proposed PSEGS. Also, by omitting most of Unit 2 (the eastern solar plant), this alternative would eliminate many of the heliostats that would be located closest to I-10. For these reasons, glint and glare impacts on motorists and pilots would be **less than PSEGS**. Mitigation measures similar to those recommended for the proposed modified project would reduce potential nuisance effects from glint and glare to less than significant.

Solar Receiver Glare Impacts That Could be Hazardous to Motorists and Pilots

This alternative involves construction of one solar power tower instead of two; therefore, glare impacts on motorists and pilots from the SRSG would be **somewhat less than PSEGS**. However, like the proposed modified project, the potential for glare from the SRSG to cause hazardous operating conditions for motorists and pilots would be potentially significant, and implementation of appropriate mitigation measures (e.g., a solar power tower luminance monitoring plan) would be required to reduce this impact to less than significant.

Visual Resources

The Reduced Acreage Alternative would, like the proposed PSEGS, deploy a field of heliostats aimed at a solar power tower, but would be approximately half the acreage of the PSEGS, with one rather than two solar towers. This alternative, like the PSEGS, would include a power transmission line from the project site to the Red Bluff Substation.

Potential for Adverse Impacts on Scenic Vistas

Construction-Related Impacts: Construction of the Reduced Acreage Alternative would cause temporary visual impacts due to the presence of equipment, materials, and a workforce, at the project site and along the transmission line route, an increase in visible traffic along I-10 and access roads, and large dust clouds generated by grading activities. The type of construction would be similar to the PSEGS, but the area of disturbance would be smaller and the construction period would be shorter. Construction impacts of this alternative on scenic vistas would thus be **less than PSEGS**.

Project Operations Impacts: No designated scenic vistas were identified in the PSEGS study area, but panoramic and highly scenic vistas from the Palen McCoy Wilderness and Chuckwalla Mountains Wilderness would be affected by this alternative. The Reduced Acreage Alternative would be smaller, but have similar industrial characteristics when viewed from the two Wilderness Areas. The predominant visual impact of the Reduced Acreage Alternative would result from the extremely bright glare of the single solar receiver. This alternative would be prominently visible from both wilderness areas and the introduction of industrial characteristics, structural visual contrast, and extremely bright glare would result in substantial adverse effects on these vistas. Although the overall affected area of visibility could be somewhat less under the Reduced Acreage Alternative compared to PSEGS, the probable difference in the extent of the viewshed would be comparatively minor and would not reduce potential impacts on the Wilderness Areas to a less-than-significant level. The impact on scenic vistas would be **somewhat less than PSEGS** but would be a significant and unavoidable impact of this alternative.

Potential to Substantially Damage Scenic Resources within a State Scenic Highway

The PSEGS site is located adjacent to the north side of I-10, which is not listed as an eligible State Scenic Highway, and no notable scenic features or historic structures are located within the site. Therefore, construction of the Reduced Acreage Alternative would not substantially damage scenic resources within a state scenic highway. This impact would be **similar to PSEGS**. The impact of operation of the Reduced Acreage Alternative on scenic resources within a state scenic highway would be **similar to PSEGS**.

Potential to Substantially Degrade the Existing Visual Character or Quality of the Site and its Surroundings

Construction-Related Impacts: As discussed above, the type of construction of the Reduced Acreage Alternative would be similar to the proposed PSEGS, but the area of disturbance would be smaller and the construction period would be shorter. Construction impacts of this alternative on visual quality would thus be **less than PSEGS**.

Project Operations Impacts: The Reduced Acreage Alternative would introduce prominent structures with industrial characteristics into the views from SR 177, the Desert Center area, I-10, Corn Springs Road, nearby Wilderness Areas, Joshua Tree National Park, and a few nearby residences. This alternative would be substantially smaller in area than the proposed PSEGS, but would include a solar tower generating strong glare that would be prominently visible and have strong visual effects over substantially the same viewshed as under PSEGS. This glare effect would be less intense than under PSEGS, but would remain considerable. The area of desert floor affected as seen from elevated Wilderness Area viewpoints would be reduced, therefore, the strong form and color contrast from the mirrored heliostat fields would affect a smaller portion of the Wilderness Areas. However, the strong glare effects would extend over roughly the same area as under the proposed PSEGS. Due to the smaller area (approximately 1,960 acres, including the common area) and single solar tower of the Reduced Acreage Alternative, the impact on visual quality would thus be **somewhat less than PSEGS**, but this alternative would result in a substantial degradation of the existing visual quality of the site and its surroundings.

Potential to Create a New Source of Substantial Light or Glare Which Would Adversely Affect Day or Nighttime Views in the Area

Construction-Related Impacts: Some construction activity could take place at night during construction of the Reduced Acreage Alternative, with lighting impacts that would extend over a much smaller area and thus be **less than PSEGS**.

Project Operations Impacts: Non-mirrored surfaces of the facilities of the Reduced Acreage Alternative have the potential to introduce reflected glare into the visual environment if the structures were light colored or included unpainted metal components, and this impact would be **similar to PSEGS**. Like the proposed modified project, with the effective implementation of Condition of Certification **VIS-1** from the PSPP 2010 Commission Decision, the Reduced Acreage Alternative would not cause excessive glare from non-mirrored surfaces (e.g., metallic or painted structures).

Glint effects, that is, inadvertent, very bright reflections of the sun's image off the heliostats under certain conditions, could present a disruptive visual distraction for motorists and other viewers, which would represent a significant glare impact of the Reduced Acreage Alternative due to the potential intensity of the effect. This glint impact would be **similar to PSEGS**. With implementation of proposed Condition of Certification **TRANS-7**, stray glint impacts from solar reflection off the heliostats under the Reduced Acreage Alternative could be reduced to a less-than-significant level.

The Reduced Acreage Alternative would include one solar tower with a solar receiver, rather than two; nevertheless, the single tower would generate strong on-going operational glare that would affect substantially the same viewshed as the proposed PSEGS. Although the overall affected area of visibility could be somewhat less under the Reduced Acreage Alternative compared to PSEGS due to the single tower configuration, the difference in the extent of the viewshed would be comparatively minor, and would not reduce potential impacts on the Wilderness Areas to a less-than-significant level. The impact of the Reduced Acreage Alternative due to glare from solar receivers would thus be **somewhat less than PSEGS**, but the glare impact would remain significant and unavoidable for this alternative.

The Reduced Acreage Alternative could generate nighttime light pollution from its operational lighting, but because there would be only one power block rather than two, this impact would be **somewhat less than PSEGS**. As with the proposed modified project, the effective implementation of Condition of Certification **VIS-4** (VIS-3 from the 2010 Commission Decision on the PSPP) would reduce the Reduced Acreage Alternative's off-site, operation-related lighting impacts to less than significant.

The Reduced Acreage Alternative would have a solar tower that would require FAA safety lighting, and this impact would be **similar to PSEGS**.

Waste Management

The Reduced Acreage Alternative with SPT Technology would involve reducing the total project acreage of the proposed modified project and effectively only building the solar tower unit and heliostat array for PSEGS Unit 1 (the western solar field). The smaller project site would result in less construction and operation waste. Potential impacts on disposal or diversion facilities would be **less than PSEGS**. The location of the SPT for PSEGS Unit 1 would be the same as the proposed modified project. Similar to the proposed modified project, staff would require investigation and remediation of soil and groundwater contamination, if it was encountered during construction and operation of this alternative. Site characterization and remediation requirements would remain the same as for the proposed PSEGS. Site worker training for potential UXO would still be required as would preparation of a UXO Identification, Training, and Reporting Plan. Potential impacts from UXO would be **similar to or less than PSEGS**. Although the reduction in acreage would reduce the potential area of exposure to unidentified UXO, it is unknown where on the site UXO could occur, or if UXO is present on the site at all.

PROJECT ALTERNATIVES COMPARED TO THE PROPOSED MODIFIED PROJECT

The environmental effects of constructing and operating the proposed modified project are described in detail for each resource topic in the **ENVIRONMENTAL ASSESSMENT** section of this staff assessment. The summary table shown in **ALTERNATIVES APPENDIX-2** compares the environmental impacts of the proposed PSEGS to the same or similar impacts that would be expected to occur with construction and operation of the project alternatives. **ALTERNATIVES APPENDIX-2** is included at the end of the Alternatives section.

ENGINEERING ASSESSMENT OF THE ALTERNATIVES

POWER PLANT EFFICIENCY AND RELIABILITY

Introduction

Comparing alternative solar power generation systems to the solar technology of the proposed PSEGS affords the opportunity to see if the project owner's system is better than any potentially viable alternative. This engineering analysis compares the solar thermal parabolic trough technology of the previously approved Reconfigured Alternatives #2 and #3 and the alternative using solar PV with single-axis tracking technology to the solar power tower (SPT) technology of the proposed PSEGS.

The key performance characteristics of an electric power generation facility are its ability to 1) produce electricity using a source of energy in as efficient a manner as possible, and 2) reliably deliver electricity upon demand. The following is an efficiency and reliability comparison among the three types of systems associated with the alternative technologies discussed in this analysis, which use solar energy as their source of electric generation.

Analysis

How efficiently a project uses land includes, but is not limited to, the site terrain and gradients, types of soils, the number and acreage of washes and waters of the U.S. and the state, and the technology. Staff calculates the relative efficiencies to verify that the project is consistent with similar technologies—not that one project is better than another project. Using land area (acre), power output (megawatt [MW]), and annual energy production (megawatt hours per year [MWh/yr]), the metric values relating to land use for the No-Project Alternative (parabolic trough), the proposed PSEGS (SPT) and the Solar PV Alternative with Single-Axis Tracking Technology yield power-based land use ratios ranging from 0.12 to 0.17 MW/acre[6] (Palen Solar Holdings 2012, NextEra Blythe Solar Energy Center 2013, Solar Millenium and Chevron Energy Solutions 2009). For energy based ratios, the range is from 337 to 372 MWh/acre-year. As a result, the comparison ratios for all three distinct technologies indicate that they are within the typical range of efficiencies expected of similar projects employing various solar technologies.

The parabolic trough technology of the No-Project Alternative requires an intensely graded, almost flat solar field to maintain a 1 percent maximum slope on the HTF (heat transfer fluid) piping. The solar collector field grading for the proposed PSEGS is not as intense because the heliostat pylons can be varied to follow the terrain and/or avoid washes or sensitive areas. However, the SPT heliostat spacing requires open pockets in its radial array to avoid steep heliostat angles in relation to the solar power tower. Additionally, the SPT collector field includes at least 15 percent excess collectors

[6] The power-based ratio is power output (MW) divided by land use area (acres). The energy based ratio is the annual energy production (MWh/year) divided by land use area (acres).

(relative to the parabolic trough) that are in standby and to account for the degradation of reflective arrays at certain angles. The rectangular Cartesian layout (x-y axis) of the PV Alternative with Single-Axis Tracking Technology provides more compactness than the two solar thermal technologies, but still has to be designed to avoid projecting shadows. Single-axis tracking brings the PV performance up to comparability with the two solar thermal technologies. Although there are incremental differences in the conversion efficiency of PV panels—12 percent for thin film cadmium telluride (CdTe) versus 15 percent for polycrystalline (Palo Verde Solar I 2012)—the variability of field conditions and the array geometry diminish the effect of the incremental differences among PV conversion efficiencies.

Given the major differences in design and operating characteristics, the differences in power and energy production when proportioned to land area are more similar than different. The comparison ratios for all three distinct technologies indicate that they are within the typical range of efficiencies expected of similar projects employing various solar technologies.

The events that prevent a facility from being available to deliver electricity are planned and unplanned outages. A key system characteristic is its ability to deliver power in response to demand. In the case of solar thermal and PV technologies, the *planned* available hours can only occur during daytime hours when the sun is visible in the sky. Within this solar timeframe, *unplanned* events like cloud covers, sandstorms, and technical failures would be factored into the predicted plant availability. Unlike the PV system, solar thermal systems like the parabolic trough (the No-Project Alternative) and the SPT (proposed PSEGS) have the advantage of load following through intermittent climatic events. The PV Tracking Alternative output closely follows the solar radiation, and output instantaneously reduces at the inception of adverse weather conditions.

Conclusion

The operation and performance of the three alternative systems presented above are comparable in efficiency. Their range of performance by factoring land area, power capacity, and energy production validates this parity.

In order to improve plant availability over existing generation of solar facilities, all three technologies must effectively use the diurnal nighttime window for covering planned maintenance and unplanned outage issues.

A notable disadvantage of the PV Tracking Alternative compared to the other two technologies discussed in this analysis is that the output of the PV system instantaneously reduces at the inception of adverse weather conditions.

TRANSMISSION SYSTEM ENGINEERING

No differences in impacts on transmission system engineering are identified for the previously approved Reconfigured Alternative #2 or #3 compared to the proposed modified project. The same is true of the Solar PV Alternative with Single-Axis Tracking Technology. Compared to the proposed PSEGS, these alternatives would generate at the same amount of power output and would interconnect to the Red Bluff Substation, as currently planned for the proposed modified project. Power would be distributed to the same transmission system. Therefore, the downstream transmission system impacts would be **similar to PSEGS**. Due to the reduction in power output for the Reduced Acreage Alternative with SPT Technology, this alternative could reduce the potential impacts on the downstream transmission system compared to the proposed PSEGS. However, no new or significant impacts would occur to the transmission system from any of the alternatives. For all the project alternatives, no new or different mitigation measures would be required.

ENVIRONMENTALLY SUPERIOR ALTERNATIVE

The project alternatives that are included in staff's analysis are those that could potentially attain most of the basic objectives of the project while avoiding or substantially lessening the significant impacts of the proposed project.

SUMMARY CONCLUSIONS FOR THE PROJECT ALTERNATIVES

No-Project Alternative

Staff compared the impacts of the previously approved Reconfigured Alternative #2 and #3 (i.e., the No-Project Alternative) to the same or similar impacts for the proposed PSEGS. In no instance did staff identify noteworthy differences in impacts between Reconfigured Alternatives #2 and #3, and for all intents and purposes, impacts under the No-Project Alternative apply to either of the approved alternatives from the original proceeding.

Under the proposed PSEGS, several impacts would remain either *potentially significant and unavoidable* or *significant and unavoidable* after mitigation. These impacts could potentially be reduced to less than significant under the No-Project Alternative with implementation of mitigation measures:

- **Cultural Resources** – Potential to substantively degrade, directly or indirectly, prehistoric or historical archaeological resources *beyond* the facility site, resources recommended or assumed to be historically significant.
- **Cultural Resources** – Potential for cumulatively considerable degradation of prehistoric or historical archaeological resources *beyond* the facility site, resources recommended or assumed to be historically significant.
- **Cultural Resources** – Potential impacts on a significant built-environment cultural resource (Desert Center) *beyond* the site.
- **Cultural Resources** – Potential to substantively degrade, directly or indirectly, ethnographic resources *beyond* the facility site, resources recommended or assumed to be historically significant.
- **Cultural Resources** – Potential for cumulatively considerable degradation of ethnographic resources *beyond* the facility site, resources recommended or assumed to be historically significant.

This alternative would not involve construction of any structures resembling the power towers of the proposed PSEGS. Staff identifies a potentially significant impact on avian species that could remain *significant and unavoidable* even after mitigation. For impacts on **Visual Resources**, staff identifies a *significant and unavoidable* impact from glint and glare effects of the high-profile solar receiver steam generators. These two impacts would not occur with construction and operation of Reconfigured Alternative #2 or #3:

- **Biological Resources** – Potential impacts on avian species from exposure to concentrated solar flux.
- **Visual Resources** – Glint or glare effects from high-profile solar receiver steam generators.

In general, staff concludes that without the solar power towers that would be constructed under the proposed modified project, some impacts on **Biological Resources**, **Cultural Resources**, **Geology and Paleontology**, **Traffic and Transportation**, and **Visual Resources** would be less than PSEGS, to varying degrees, under this alternative.

For **Biological Resources**, impacts on avian species from the effects of exposure to concentrated solar flux in the airspace over the solar collector array fields would not occur under this alternative, whereas under the proposed PSEGS, the impact could remain significant and unavoidable after mitigation. The extent and nature of adverse impacts from the No-Project Alternative are uncertain, but could include injury and mortality due to collisions with project features and possibly other physiological stress mechanisms. Depending on the severity of the impacts and the species affected, these impacts could remain significant and unavoidable after implementation of all feasible mitigation measures. Biological resources staff concludes that direct effects on sand transport Zones II and III and indirect effects on Zone III would be “somewhat less than PSEGS” under this alternative. Impacts on Mojave fringe-toed lizard would also be “somewhat less than PSEGS.” Like the proposed modified project, implementation of appropriate mitigation measures could reduce impacts on the sand transport corridor, sand dunes, and Mojave fringe-toed lizard to less than significant.

For potentially significant impacts on avian species from collisions with the solar collectors and other equipment, staff concludes that the impacts would be “similar to PSEGS” even though the absence of the SPTs under this alternative would eliminate the potential for avian species to collide with those extremely tall structures. Biological resources staff recommends mitigation measures for impacts on avian species from potential collisions with project structures or exposure to solar flux (please refer to Conditions of Certification **BIO-16a** and **BIO-16b** in the **BIOLOGICAL RESOURCES** section of this staff assessment). With implementation of all feasible mitigation measures, cumulative impacts could remain significant and unavoidable.

Cultural Resources staff concludes that Reconfigured Alternative #2 or #3 would have a much lower potential to substantively degrade prehistoric or historical archaeological resources *beyond* the site compared to the proposed PSEGS. This alternative would also greatly reduce direct and cumulative impacts relating to degradation of ethnographic resources *beyond* the site. Under the proposed PSEGS, no feasible mitigation measures are identified to reduce these impacts to less than significant, and they would remain significant and unavoidable. Because of the reduced severity of the visual intrusion of the parabolic trough technology on the cultural landscape that covers much of the Chuckwalla Valley and the flanks of the surrounding mountains, these direct and cumulative impacts could be reduced to less than significant with implementation of appropriate mitigation measures.

As one consequence of the much higher vertical profile of the proposed PSEGS, which staff concludes would result in significant and immitigable impacts on off-site built-environment resources, staff concludes that construction and operation of Reconfigured Alternative #2 or #3 would cause impacts on built-environment resources *beyond* the site that would be "much less than PSEGS."

Although construction of Reconfigured Alternative #2 or #3 would require substantial site grading and excavation, the conventional excavation methods used to install the parabolic trough system allows retrieval of subsurface soils or any fossils contained within those soils. Any fossil discoveries would be uncovered, collected, and recorded according to professional standards and practices, and impacts on **Paleontological Resources** could be reduced to less than significant. Under the proposed modified project, installation of the pylons supporting the heliostat mirrors would cause the permanent loss and destruction of any fossils that could be present in subsurface soils. Staff recommends a subsurface site characterization prior to the start of ground disturbance to allow refinement of mitigation options for impacts on those resources; implementation of Condition of Certification **PAL-9** would reduce impacts on paleontological resources to less than significant.

For **Geological Resources** impacts, the overall potential for impacts to occur from all identified geologic hazards for Reconfigured Alternative #2 or #3 would be "much less than PSEGS." Mitigation measures to reduce the risk of damage to the facility from geologic hazards would remain the same regardless of the project technology.

Traffic and Transportation staff concludes that the sun's reflection off the parabolic mirrors of this alternative would be much more diffuse and produce a greatly reduced glare effect compared to the nearly planar heliostat mirror collectors of the proposed PSEGS. The potential for the solar collectors to cause distractive and uncomfortable glint and glare impacts on motorists and pilots in the project area would be "much less than PSEGS." Mitigation measures similar to those recommended for the proposed modified project would reduce potential nuisance effects of glint and glare to less than significant. Under the proposed modified project, the potential for glare effects from the SPTs (i.e., the solar receivers) to cause hazardous conditions for motorists and pilots is considered potentially significant. Given that this alternative would not include power towers topped by brightly glowing SRSGs, the potential for glare impacts to cause hazardous operating conditions for motorists and pilots would be “much less than PSEGS.” Hazardous glare impacts from Reconfigured Alternative #2 or #3 would be less than significant, and no mitigation measures would be required.

Several impacts on **Visual Resources** under this alternative are described as “similar to PSEGS.” However, this alternative would not include any structures resembling the extremely tall power towers topped by brightly glowing SRSGs, and no adverse impacts on visual resources would occur relating to the glint and glare effects of the solar receivers. This impact would remain significant and unavoidable under the proposed PSEGS. The increased project site footprint for this alternative would increase the extent of the solar collector fields and possibly the extent of the project area across the horizontal plane. Although the prominence of the facility would be reduced without the SPTs in views from the Wilderness Areas, this alternative would have similar industrial-type characteristics that would contrast greatly with the landscape. Staff concludes that the impact on scenic vistas would be “somewhat less than PSEGS.”

Implementation of Reconfigured Alternative #2 or #3 would increase the project site footprint and require up to approximately 570 more acres compared to the proposed modified project. As a result of the increased acreage, impacts on special-status plant species, desert tortoise, and other special-status terrestrial wildlife species (excluding Mojave fringe-toed lizard) would be “greater than PSEGS.” Because of the greater extent of site grading that is required for parabolic trough projects, impacts on on-site drainages and jurisdictional waters would be “much greater than PSEGS.” Implementation of appropriate mitigation measures would reduce these impacts on **Biological Resources** to less than significant.

Due to the use of a highly combustible HTF and large quantities of other combustible and hazardous materials, impacts on fire response and hazardous materials spill response would be “much greater than PSEGS” under this alternative. Impacts on **Fire Protection**, **Hazardous Materials Management**, and **Waste Management** would be reduced to less than significant with implementation of appropriate mitigation measures.

For the topic of **Land Use**, the impact addressing compatibility with applicable plans, policies and regulations is “somewhat greater than PSEGS” due to the additional requirement to comply with the Riverside County General Plan and several ordinances and policies addressing solar development on unincorporated county land.

For impacts on **Soil and Water Resources**, staff concludes that increased earthwork during project construction would greatly increase the potential for soil erosion by wind and water during project construction. Although this impact would be “much greater than PSEGS,” implementation of standard mitigation measures would reduce this construction-related impact to less than significant. Most other impacts on soil and water resources are considered to be “somewhat greater than PSEGS” or “greater than PSEGS,” and these impacts would be reduced to less than significant with implementation of appropriate mitigation measures.

For the topics of **Air Quality** and **Public Health**, staff concludes that comparative impacts would be “similar to PSEGS” or “somewhat greater than PSEGS” with no change to the comparative impact conclusions. However, more stringent mitigation measures would be required to ensure that the impacts from constructing and operating Reconfigured Alternative #2 or #3 would not be considered cumulatively significant for ozone.

The avoidance or substantial reduction of several impacts on **Biological Resources**, **Cultural Resources**, **Geology and Paleontological Resources**, and **Visual Resources** is considered an environmental benefit of this alternative compared to the proposed PSEGS. For impacts on **Biological Resources**, staff concludes that impacts on the sand transport corridor, sand dunes, and the Mojave fringe-toed lizard would be “somewhat less than PSEGS.” Other impacts on biological resources that are considered “greater than PSEGS” could be reduced to less than significant with implementation of appropriate mitigation measures. If reducing or avoiding several direct and indirect environmental impacts is a critical factor, then either Reconfigured Alternative #2 or #3 would be environmentally superior to the proposed modified project.

Although construction and operation of Reconfigured Alternative #2 or #3 could potentially attain most of the basic project objectives, it is unknown how and to what extent changing the project technology back to a parabolic trough technology could affect project viability.

Solar PV Alternative with Single-Axis Tracking Technology

Under the proposed PSEGS, several impacts on **Cultural Resources** would remain *significant and unavoidable* after mitigation. These impacts could potentially be reduced to less than significant under this alternative with implementation of mitigation measures:

- **Cultural Resources** – Potential to substantively degrade, directly or indirectly, prehistoric or historical archaeological resources *beyond* the facility site, resources recommended or assumed to be historically significant.
- **Cultural Resources** – Potential for cumulatively considerable degradation of prehistoric or historical archaeological resources *beyond* the facility site, resources recommended or assumed to be historically significant.
- **Cultural Resources** – Potential impacts on a significant built-environment cultural resource (Desert Center) *beyond* the site.
- **Cultural Resources** – Potential to substantively degrade, directly or indirectly, ethnographic resources *beyond* the facility site, resources recommended or assumed to be historically significant.
- **Cultural Resources** – Potential for cumulatively considerable degradation of ethnographic resources *beyond* the facility site, resources recommended or assumed to be historically significant.

This alternative would not involve construction of any structures resembling the power towers of the proposed PSEGS, and three impacts identified by staff as *potentially significant* or *significant and unavoidable* under the proposed modified project would not occur with construction and operation of the Solar PV Alternative:

- **Biological Resources** – Potential impacts on avian species from exposure to concentrated solar flux.
- **Traffic and Transportation** – Solar receiver glare impacts that could be hazardous to motorists and pilots.
- **Visual Resources** – Glint or glare effects from high-profile solar receiver steam generators.

Without the SPTs that would be constructed for the proposed modified project, staff concludes that some impacts on **Biological Resources**, **Cultural Resources**, **Fire Protection**, **Geological Resources**, **Hazardous Materials Management**, **Public Health**, **Traffic and Transportation**, and **Visual Resources** would be less than PSEGS, to varying degrees, under this alternative.

For **Biological Resources**, the Solar PV Alternative would not concentrate solar flux, thereby eliminating a significant and unavoidable impact of the proposed PSEGS. The solar collectors installed at utility-scale renewable solar facilities—both the reflective surfaces of the mirrored heliostats and parabolic troughs and the less reflective glass solar PV panels—definitely pose collision hazards for avian species. For potentially significant impacts on avian species from collisions with the solar PV panels, transmission lines, and other equipment, staff concludes that the impacts would be "similar to PSEGS." For the proposed PSEGS, biological resources staff is recommending mitigation measures for impacts on avian species relating to potential collisions with project structures or exposure to solar flux (Conditions of Certification **BIO-16a** and **BIO-16b** in the **BIOLOGICAL RESOURCES** section of this staff assessment). Under the Solar PV Alternative, with implementation of all feasible mitigation measures, indirect and cumulative collision impacts could remain significant after mitigation.

Biological resources staff concludes that impacts on special-status plant species, waters of the state, and desert tortoise and other special-status terrestrial wildlife species would be "similar to PSEGS." Potential impacts on groundwater dependent plants and wildlife species would be "somewhat less than PSEGS." Direct impacts on the sand transport corridor, sand dunes, and Mojave fringe-toed lizard would likely be "somewhat less than PSEGS." A sand transport model is not available for this alternative; therefore, staff is unable to reach defensible comparative impact conclusions for potential indirect impacts on the sand transport corridor, sand dunes, and the Mojave fringe-toed lizard.

For **Cultural Resources**, staff concludes that the Solar PV Alternative would have a much lower potential to substantively degrade prehistoric or historical archaeological resources *beyond* the site compared to the proposed PSEGS. This alternative would also greatly reduce direct and cumulative impacts relating to degradation of ethnographic resources *beyond* the site. Staff concludes that the Solar PV Alternative would cause impacts on built-environment resources *beyond* the site that would be "much less than PSEGS." These direct and cumulative impacts could be reduced to less than significant with implementation of appropriate mitigation measures.

For **Fire Protection** impacts, staff concludes that construction-related direct and cumulative impacts on the Riverside County Fire Department under the Solar PV Alternative would be "much less than PSEGS." Because of the reduced need to transport, store, and use hazardous materials under this alternative, the potential for exposure to hazardous materials would be "much less than PSEGS." Overall, impacts on emergency services during project operations for the Solar PV Alternative would be "much less than PSEGS." Mitigation measures like those required for the proposed PSEGS would reduce impacts relating to **Fire Protection** and **Hazardous Materials Management** to less than significant.

Impacts relating to **Geology and Paleontology** would be "much less than PSEGS" or "somewhat less than PSEGS." The elimination of deep foundations would decrease the potential for encountering fossil bearing strata. Because traditional power plant structures on large foundations would not be required for the Solar PV Alternative, impacts on paleontological resources would be "somewhat less than PSEGS." The overall potential for impacts to occur from all identified geologic hazards for this alternative would be "much less than PSEGS." Mitigation measures would reduce the risk of damage from geologic hazards to less than significant.

For **Public Health** impacts, this alternative would not cause emissions of toxic air contaminants from boiler combustion and cooling towers, and staff considers the overall potential public health risks from the Solar PV Alternative to be "less than PSEGS." Because the Solar PV Alternative does not require a power plant cooling system, no public health impact would occur under this alternative relating to potential exposure to bacterial growth in the cooling systems that are required for traditional power plants.

For **Traffic and Transportation** impacts, staff concludes that the less reflective qualities of the PV panels compared to the heliostat mirrors would greatly reduce potential nuisance glint and glare impacts on motorists, and this impact would be "much less than PSEGS." This alternative would not include glare-producing SRSGs and power towers, and the potential for glare impacts to cause hazardous conditions for motorists and pilots would not occur under the Solar PV Alternative.

For **Visual Resources** impacts, staff concludes that the greatly reduced vertical profile and visual prominence of the structures for the Solar PV Alternative would reduce the potential for this alternative to cause adverse impacts on scenic vistas during project operations. This alternative would also greatly reduce the potential to substantially degrade the existing visual character or quality of the site and its surroundings. Staff concludes that both impacts would be "less than PSEGS." However, due to the substantial contrast of any utility-scale renewable solar facility with the landscape, these impacts would remain significant and unavoidable after mitigation.

This alternative would not include any structures resembling the extremely tall power towers topped by brightly glowing SRSGs, and no adverse impacts on **Visual Resources** would occur from the glint and glare effects of the proposed PSEGS solar receivers. Under the proposed PSEGS, this impact would remain significant and unavoidable.

The Solar PV Alternative would not require the bulky power block structures of the proposed PSEGS, and the potential effects of reflected glint or glare would be "much less than PSEGS." Due to the lower reflectivity of PV panels compared to heliostat mirrors, the potential for glint or glare to present a disruptive visual distraction for motorists and other viewers would be "much less than PSEGS." Like the proposed PSEGS, these potential **Visual Resources** impacts would be reduced to less than significant with implementation of appropriate mitigation measures.

For **Air Quality** impacts, emissions of criteria air pollutants during project operations would be "less than PSEGS," and like the proposed PSEGS, all air quality impacts would be reduced to less than significant.

For impacts on **Soil and Water Resources**, staff concludes that characteristic impacts on water quality caused by the presence of traditional power plant facilities would be "much less than PSEGS" for the Solar PV Alternative. Other impacts on soil and water resources are considered "somewhat less than PSEGS," "somewhat greater than PSEGS," or "similar to PSEGS," and these impacts would be reduced to less than significant with implementation of appropriate mitigation measures.

The avoidance or substantial reduction of several impacts on **Biological Resources**, **Cultural Resources**, **Traffic and Transportation**, and **Visual Resources** is considered an environmental benefit of this alternative compared to the proposed PSEGS. For **Biological Resources**, the primary benefit of this alternative compared to the proposed PSEGS is the elimination of the potential effects of solar flux on avian species. For **Cultural Resources**, **Traffic and Transportation**, and **Visual Resources** impacts, the Solar PV Alternative with its much lower vertical profile and reduced potential for operational glint and glare effects would offer the potential to develop mitigation measures that would go furthest toward reducing impacts on these resources.

If reducing or avoiding several direct and indirect environmental impacts and improving the effectiveness of mitigation measures are the critical factors, then the Solar PV Alternative with Single-Axis Tracking Technology would be environmentally superior to the proposed modified project.

Although construction and operation of the Solar PV Alternative could potentially attain many of the basic project objectives, it is unknown whether and to what extent the change of project technology would affect project viability.

Reduced Acreage Alternative with SPT Technology

For most environmental resources, comparative impacts under this alternative are described as "less than PSEGS," "somewhat less than PSEGS," "similar to PSEGS," or "same as PSEGS." Of the impacts on **Biological Resources**, the Reduced Acreage Alternative would avoid all impacts on mapped populations of the special-status plant species, ribbed cryptantha.

Although some of the **Biological Resources** impacts would be reduced under this alternative compared to PSEGS, staff concludes that all of these impacts would be significant. Implementation of mitigation measures would reduce these impacts to less-than-significant levels:

- Impacts on special-status plant species
- Impacts on waters of the state
- Impacts on desert tortoise
- Impacts on special-status terrestrial wildlife species (kit fox, American badger)
- Impacts on sand transport corridor
- Impacts on sand dunes and Mojave fringe-toed lizard[7]

For **Biological Resources** impacts, staff concludes that impacts on special-status plant species would be "much less than PSEGS" under this alternative. The Reduced Acreage Alternative would avoid impacts on mapped populations of ribbed cryptantha and eliminate impacts on one mapped population of Harwood's milkvetch, both of which are considered special-status species under CEQA. Impacts on waters of the state, desert dry wash woodland, and unvegetated ephemeral dry washes would be reduced under this alternative. Staff concludes that direct impacts on aeolian sand corridors Zone II and Zone III would be "less than PSEGS." Impacts on Mojave fringe-toed lizard would likely be "less than PSEGS." Staff concludes that impacts on kit fox, desert tortoise, and American badger would be "much less than PSEGS." The Reduced Acreage Alternative would greatly reduce impacts on burrowing owl habitat, and as a result, impacts on this species would likely be "much less than PSEGS." The potential impact on groundwater dependent ecosystems would be "somewhat less than PSEGS." Like the proposed modified project, implementation of appropriate mitigation measures would reduce these biological resources impacts to less-than-significant levels. Potential impacts on avian species from the effects of exposure to solar flux and collisions with project structures are estimated to be "less than PSEGS," although the impacts could remain significant and unavoidable after mitigation.

For impacts on **Cultural Resources**, staff characterizes the net effect of this alternative on prehistoric and historical resources as "similar to PSEGS." For impacts on **Geology**

[7] Without a predictive model to project impacts, indirect impacts on the sand transport corridor, sand dunes, and the Mojave fringe-toed lizard are unquantifiable.

and Paleontology, the impact on paleontological resources would be “less than PSEGS.” This alternative would omit Unit 2 (the eastern solar plant) and many of the heliostats that would be located closest to I-10, and glint and glare impacts from the heliostats would be “less than PSEGS.” The same mitigation measures proposed for PSEGS to reduce solar collector glint and glare impacts would apply to this alternative. For **Traffic and Transportation** and **Visual Resources**, no significant impacts would be greatly reduced or avoided under this alternative.

Staff identifies several impacts on **Biological Resources** that would be “much less than PSEGS,” and staff considers this to be the primary benefit of this alternative compared to the proposed modified project. If reducing the overall extent of impacts on biological resources is the critical factor, then the Reduced Acreage Alternative would be somewhat superior to the proposed modified project.

Although the Reduced Acreage Alternative could potentially attain many of the basic project objectives, it is unknown how eliminating the eastern solar plant would affect project viability.

ALTERNATIVES APPENDIX-1: STAFF CONTRIBUTORS TO THE COMPARATIVE ANALYSIS OF ALTERNATIVES

This appendix lists staff responsible for specific technical analyses in the **ALTERNATIVES** section of this staff assessment. Staff names are listed with their area of technical expertise.

Technical Area	Staff
Air Quality	Jacquelyn Leyva Record
Biological Resources	Carol Watson Chris Huntley
Cultural Resources	Michael D. McGuirt, RPA Thomas M. Gates, Ph.D.
Fire Protection	Alvin Greenberg, Ph.D.
Geology and Paleontology	Casey W. Weaver, CEG
Hazardous Materials Management	Alvin Greenberg, Ph.D.
Land Use	James Adams
Power Plant Efficiency and Reliability	Edward Brady, P.E. Shahab Khoshmashrab, P.E.
Public Health	Huei-An (Ann) Chu, Ph.D.
Socioeconomics	Lisa Worrall
Soil and Water Resources	Marylou Taylor, P.E.
Traffic and Transportation	Andrea Koch-Eckhardt David Flores Gregg Irvin, Ph.D. Alvin Greenberg, Ph.D.
Transmission System Engineering	Laiping Ng Mark Hesters
Visual Resources	William Kanemoto Gregg Irvin, Ph.D.
Waste Management	Christopher Dennis, PG

ALTERNATIVES APPENDIX-1: STAFF CONTRIBUTORS TO THE COMPARATIVE ANALYSIS OF ALTERNATIVES

This appendix lists staff responsible for specific technical analyses in the **ALTERNATIVES** section of this staff assessment. Staff names are listed with their area of technical expertise.

Technical Area	Staff
Air Quality	Jacquelyn Leyva Record
Biological Resources	Carol Watson Chris Huntley
Cultural Resources	Michael D. McGuirt, RPA Thomas M. Gates, Ph.D.
Fire Protection	Alvin Greenberg, Ph.D.
Geology and Paleontology	Casey W. Weaver, CEG
Hazardous Materials Management	Alvin Greenberg, Ph.D.
Land Use	James Adams
Power Plant Efficiency and Reliability	Edward Brady, P.E. Shahab Khoshmashrab, P.E.
Public Health	Huei-An (Ann) Chu, Ph.D.
Socioeconomics	Lisa Worrall
Soil and Water Resources	Marylou Taylor, P.E.
Traffic and Transportation	Andrea Koch-Eckhardt David Flores Gregg Irvin, Ph.D. Alvin Greenberg, Ph.D.
Transmission System Engineering	Laiping Ng Mark Hesters
Visual Resources	William Kanemoto Gregg Irvin, Ph.D.
Waste Management	Christopher Dennis, PG

Alternatives Appendix-2
Summary Comparison of Impacts of the Project Alternatives to the Proposed Modified Project
(Please see explanatory notes at the bottom of the table)

Environmental Effect	Proposed PSEGS	No-Project Alternative	Solar PV Alternative with Single-Axis Tracking Technology	Reduced Acreage Alternative with SPT Technology
		Reconfigured Alternative #2 or #3		
Air Quality				
Construction-related emissions	SM (locally)	Similar to PSEGS (SM)	Similar to PSEGS (SM)	Somewhat less than PSEGS (SM)
Project operations emissions	SM (locally)	Somewhat greater than PSEGS (SM)	Less than PSEGS (SM)	Similar to PSEGS (SM)
Reduction in greenhouse gases	B (system wide)	Similar to PSEGS (B)	Somewhat greater than PSEGS (B)	Similar to PSEGS (B)
Biological Resources				
Impacts on special-status plant species	SM	Greater than PSEGS (SM)	Similar to PSEGS (SM)	Much less than PSEGS (SM)
Impacts on waters of the state	SM	Much greater than PSEGS (SM)	Similar to PSEGS (SM)	Much less than PSEGS (SM)
Impacts on desert tortoise	SM	Greater than PSEGS (SM)	Similar to PSEGS (SM)	Much less than PSEGS (SM)
Impacts on special-status terrestrial wildlife species (kit fox, American badger)	SM	Greater than PSEGS (SM)	Similar to PSEGS (SM)	Much less than PSEGS (SM)
Potential impacts on avian species from collisions with project features	PSU	Similar to PSEGS (PSU)	Similar to PSEGS (PSU)	Less than PSEGS (PSU)
Potential impacts on avian species from exposure to concentrated solar flux	PSU	—	—	Less than PSEGS (PSU)
Potential impacts on groundwater dependent ecosystems	SM	Somewhat greater than PSEGS (SM)	Somewhat less than PSEGS (SM)	Somewhat less than PSEGS (SM)

Alternatives Appendix-2
Summary Comparison of Impacts of the Project Alternatives to the Proposed Modified Project
(Please see explanatory notes at the bottom of the table)

Environmental Effect	**Proposed PSEGS**	**No-Project Alternative**	**Solar PV Alternative with Single-Axis Tracking Technology**	**Reduced Acreage Alternative with SPT Technology**
		Reconfigured Alternative #2 or #3		
Impacts on sand transport corridor	SM	Somewhat less than PSEGS (SM)	Somewhat less than PSEGS (SM) *(see biological resources note)*	Less than PSEGS (SM) *(see biological resources note)*
2 Impacts on sand dunes and Mojave fringe-toed lizard	SM	Somewhat less than PSEGS (SM)	Somewhat less than PSEGS (SM) *(see biological resources note)*	Less than PSEGS (SM) *(see biological resources note)*
Biological resources note: Comparative impacts for the Solar PV Alternative and the Reduced Acreage Alternative for indirect impacts on the sand transport corridor, sand dune habitat, and Mojave fringe-toed lizard cannot reasonably be characterized without further data and use of a sand transport model.				
Cultural Resources				
Potential to substantively degrade, directly or indirectly, prehistoric or historical archaeological resources *on* the facility site, resources recommended or assumed to be historically significant *(see cultural resources note 1)*	PSM	Somewhat greater than PSEGS (SM)	Similar to PSEGS (PSM)	Less than PSEGS (PSM)
Potential to substantively degrade, directly or indirectly, prehistoric or historical archaeological resources *beyond* the facility site, resources recommended or assumed to be historically significant	SU	Much less than PSEGS (SM)	Much less than PSEGS (SM)	Similar to PSEGS (SU)

Alternatives Appendix-2
Summary Comparison of Impacts of the Project Alternatives to the Proposed Modified Project
(Please see explanatory notes at the bottom of the table)

Environmental Effect	Proposed PSEGS	No-Project Alternative	Solar PV Alternative with Single-Axis Tracking Technology	Reduced Acreage Alternative with SPT Technology
		Reconfigured Alternative #2 or #3		
Potential for cumulatively considerable degradation of prehistoric or historical archaeological resources *beyond* the facility site, resources recommended or assumed to be historically significant	SU	Much less than PSEGS (PSM)	Much less than PSEGS (SM)	Similar to PSEGS (SU)
Potential impacts on significant built-environment cultural resources *on* the site	LS	Similar to PSEGS (LS)	Similar to PSEGS (LS)	Similar to PSEGS (LS)
3 Potential impacts on significant built-environment cultural resources (Desert Center, Eagle Mountain Mine) *beyond* the site	SU	Much less than PSEGS (LS)	Much less than PSEGS (SM)	Similar to PSEGS (SU)
Potential to substantively degrade, directly or indirectly, ethnographic resources *on* the facility site, resources recommended or assumed to be historically significant	PSM	Similar to PSEGS (PSM)	Similar to PSEGS (PSM)	Similar to PSEGS (PSM)
Potential for cumulatively considerable degradation of ethnographic resources *on* the facility site, resources recommended or assumed to be historically significant	LS	Similar to PSEGS (LS)	Similar to PSEGS (LS)	Similar to PSEGS (LS)
Potential to substantively degrade, directly or indirectly, ethnographic resources *beyond* the facility site, resources recommended or assumed to be historically significant	SU	Much less than PSEGS (PSM)	Much less than PSEGS (SM)	Similar to PSEGS (SU)
Potential for cumulatively considerable degradation of ethnographic resources *beyond* the facility site, resources recommended or assumed to be historically significant	SU	Much less than PSEGS (PSM)	Much less than PSEGS (SM)	Similar to PSEGS (SU)
Cultural resources note: For all alternatives, “site” means the facility site proper and does not include linear or ancillary infrastructure away from the facility site.				

Alternatives Appendix-2
Summary Comparison of Impacts of the Project Alternatives to the Proposed Modified Project
(Please see explanatory notes at the bottom of the table)

Environmental Effect	Proposed PSEGS	No-Project Alternative	Solar PV Alternative with Single-Axis Tracking Technology	Reduced Acreage Alternative with SPT Technology
		Reconfigured Alternative #2 or #3		
Fire Protection				
Construction-Related Impacts				
Impacts on the Riverside County Fire Department	SM	Somewhat greater than PSEGS (SM)	Much less than PSEGS (SM)	Same as PSEGS (SM)
Project Operations Impacts				
4 Become familiar with and plan for emergency responses	SM	Less than PSEGS (SM)	Much less than PSEGS (SM)	Same as PSEGS (SM)
Conduct plan reviews, inspections, and permitting	SM	Somewhat greater than PSEGS (SM)	Much less than PSEGS (SM)	Same as PSEGS (SM)
Fire response	SM	Much greater than PSEGS (SM)	Much less than PSEGS (SM)	Same as PSEGS (SM)
Hazardous materials spill response	SM	Much greater than PSEGS (SM)	Much less than PSEGS (SM)	Same as PSEGS (SM)
Rescue	SM	Somewhat less than PSEGS (SM)	Somewhat less than PSEGS (SM)	Same as PSEGS (SM)
Emergency medical services	SM	Same as PSEGS (SM)	Much less than PSEGS (SM)	Same as PSEGS (SM)
Geology and Paleontology				
Potential impacts from strong seismic shaking	SM	Much less than PSEGS (SM)	Much less than PSEGS (SM)	Somewhat less than PSEGS (SM)

Alternatives Appendix-2
Summary Comparison of Impacts of the Project Alternatives to the Proposed Modified Project
(Please see explanatory notes at the bottom of the table)

Environmental Effect	Proposed PSEGS	No-Project Alternative	Solar PV Alternative with Single-Axis Tracking Technology	Reduced Acreage Alternative with SPT Technology
		Reconfigured Alternative #2 or #3		
Potential impacts from soil failure caused by liquefaction, hydrocollapse, and/or dynamic compaction	SM	Much less than PSEGS (SM)	Much less than PSEGS (SM)	Somewhat less than PSEGS (SM)
Potential impacts on paleontological resources	SM	Less than PSEGS (SM)	Somewhat less than PSEGS (SM)	Less than PSEGS (SM)
Potential impacts on geological or mineralogical resources	—	—	—	—
Hazardous Materials Management				
Construction-Related Impacts				
Potential for spills or other releases of hazardous materials to occur on-site	SM	Same as PSEGS (SM)	Same as PSEGS (SM)	Same as PSEGS (SM)
Potential for spills or other releases of hazardous materials to occur off-site	LS	Same as PSEGS (LS)	Same as PSEGS (LS)	Same as PSEGS (LS)
Project Operations Impacts				
Potential for spills or other releases of hazardous materials to occur on-site	SM	Much greater than PSEGS (SM)	Much less than PSEGS (SM)	Same as PSEGS (SM)
Potential for spills or other releases of hazardous materials to occur off-site	LS	Much greater than PSEGS (SM)	Much less than PSEGS (LS)	Same as PSEGS (LS)
Land Use				
Compatibility with land use plan, policy, or regulation	SM	Somewhat greater than PSEGS (SM)	Similar to PSEGS (SM)	Similar to PSEGS (SM)

Alternatives Appendix-2
Summary Comparison of Impacts of the Project Alternatives to the Proposed Modified Project
(Please see explanatory notes at the bottom of the table)

Environmental Effect	Proposed PSEGS	No-Project Alternative	Solar PV Alternative with Single-Axis Tracking Technology	Reduced Acreage Alternative with SPT Technology
		Reconfigured Alternative #2 or #3		
Public Health				
Potential for project construction to cause air toxics-related or other impacts that could affect public health	LS	Somewhat greater than PSEGS (LS)	Similar to PSEGS (LS)	Less than PSEGS (LS)
Potential for project operations to cause air toxics-related or other impacts that could affect public health	PSM	Similar to PSEGS (PSM)	Less than PSEGS (LS)	Less than PSEGS (PSM)
Socioeconomics				
Environmental justice population within 6-mile buffer	—	—	—	—
Induce substantial population growth in an area, either directly or indirectly	LS	Similar to PSEGS (LS)	Similar to PSEGS (LS)	Somewhat less than PSEGS (LS)
Displace substantial numbers of people and/or existing housing, necessitating the construction of replacement housing elsewhere	LS	Similar to PSEGS (LS)	Similar to PSEGS (LS)	Somewhat less than PSEGS (LS)
Adversely impact acceptable levels of service for police protection, schools, and parks and recreation	LS	Similar to PSEGS (LS)	Similar to PSEGS (LS)	Somewhat less than PSEGS (LS)
Increased property taxes, construction and operation employment income, and increased state and local taxes and fees	B	Similar to PSEGS (B)	Similar to PSEGS (B)	Somewhat less than PSEGS (B)
Soil and Water Resources

Alternatives Appendix-2
Summary Comparison of Impacts of the Project Alternatives to the Proposed Modified Project
(Please see explanatory notes at the bottom of the table)

Environmental Effect	Proposed PSEGS	No-Project Alternative	Solar PV Alternative with Single-Axis Tracking Technology	Reduced Acreage Alternative with SPT Technology
		Reconfigured Alternative #2 or #3		
Waste Management				
Potential for unexploded ordnance to be present at the project site	PSM	Similar to PSEGS (PSM)	Similar to PSEGS (PSM)	Similar to or less than PSEGS (PSM)
Potential for impacts on human health and the environment relating to past or present soil or water contamination	LS	Similar to PSEGS (LS)	Similar to PSEGS (LS)	Similar to or less than PSEGS (LS)
Potential for impacts on human health and the environment relating to potential waste discharges	LS	Much greater than PSEGS (PSM)	Similar to PSEGS (LS)	Similar to or less than PSEGS (LS)
Potential for disposal or diversion of project materials to cause impacts on existing waste disposal or diversion facilities	LS	Similar to PSEGS (LS)	Similar to PSEGS (LS)	Less than PSEGS (LS)

Notes: The comparison of impacts to the proposed modified project is conveyed, for most impacts, using these terms in a graded scale:

- Much less than PSEGS
- Less than PSEGS
- Somewhat less than PSEGS
- Similar to PSEGS
- Same as PSEGS
- Somewhat greater than PSEGS
- Greater than PSEGS
- Much greater than PSEGS

Notes: Impact conclusions for the proposed modified project and the comparative impacts for the alternatives are shown using these abbreviations:

— = no impact
B = beneficial impact
LS = less-than-significant impact, no mitigation required
SM or PSM = significant or potentially significant impact that can be mitigated to less than significant
SU or PSU = significant and unavoidable or potentially significant and unavoidable impact that cannot be mitigated to less than significant

COMPLIANCE CONDITIONS
AND
COMPLIANCE MONITORING PLAN

Testimony of Eric Veerkamp

INTRODUCTION

The project's **Compliance** Conditions of Certification, including a Compliance Monitoring Plan (Compliance Plan), were established as required by Public Resources Code section 25532. The Compliance Plan, applicable to the Palen Solar Electric Generating System (PSEGS), provides a means for assuring that the facility is constructed, operated, and closed in compliance with public health and safety, environmental, all other applicable laws, ordinances, regulations, and standards (LORS), and the conditions adopted by the Energy Commission and specified in the written Decision on the Amendment, or otherwise required by law.

The Compliance Plan is composed of elements that:

- set forth the duties and responsibilities of the Compliance Project Manager (CPM), the project owner or operator (project owner), delegate agencies, and others;
- set forth the requirements for handling confidential records and maintaining the compliance record;
- state procedures for settling disputes and making post-certification changes;
- state the requirements for periodic compliance reports and other administrative procedures necessary to verify the compliance status of all Energy Commission-approved conditions of certification;
- establish contingency planning, facility non-operation protocols, and closure requirements; and
- establish a tracking method for the technical area conditions of certification that contain measures required to mitigate potentially adverse project impacts associated with construction, operation, and closure to less than a level of significance. Each technical condition of certification also includes one or more verification provisions that describe the means of assuring that the condition has been satisfied.

REVISED COMPLIANCE CONDITIONS

Recent compliance monitoring experience on large solar projects demonstrated the need to revise the **Compliance** Conditions of Certification to improve compliance enforcement. The list below summarizes the revisions.

- Definitions for specific terms pertinent to compliance monitoring, including, “Start of Construction,” “Start of Commercial Operation,” “Non-Operation and Closure,” “Site Assessment and Pre-Construction Activities,” and “Site Mobilization and Construction,” among others;

- A new subsection and expanded discussion of “Roles and Responsibilities” and new sections for “Pre-Construction and Pre-Operation Compliance Meeting” and “Energy Commission Record;” and
- New condition of certification addressing “Non-Operation” and “Facility Closure Planning.”

KEY PROJECT DEFINITIONS

The following terms and definitions help determine when various conditions of certification are implemented.

Project Certification

Project certification occurs on the day the Energy Commission dockets its Decision after adopting it at a publically noticed Business Meeting or hearing. At that time, all Energy Commission conditions of certification become binding on the project owner and the proposed facility.

Site Assessment and Pre-Construction Activities

The below-listed site assessment and pre-construction activities may be initiated or completed prior to the start of construction, subject to the CPM’s approval of the specific site assessment or pre-construction activities.

Site assessment and pre-construction activities include the following, but only to the extent the activities are minimally disruptive to soil and vegetation and will not affect listed or special-status species or other sensitive resources:

1. the installation of environmental monitoring equipment;
2. a minimally invasive soil or geological investigation;
3. a topographical survey;
4. any other study or investigation, such as preconstruction surveys and tortoise clearance work determine the environmental acceptability or feasibility of the use of the site for any particular facility; and,
5. any minimally invasive work to provide safe access to the site for any of the purposes specified in 1-4 above.

Site Mobilization and Construction

When a condition of certification requires the project owner to take an action or obtain CPM approval prior to the start of construction, or within a period of time relative to the start of construction, that action must be taken, or approval must be obtained, prior to any site mobilization or construction activities, as defined below.

Site mobilization and construction activities are those necessary to provide site access for construction mobilization and facility installation, including both temporary and permanent equipment and structures, as determined by the CPM.

Site mobilization and construction activities include, but are not limited to:

1. ground disturbance activities like grading, boring, trenching, leveling, mechanical clearing, mowing, grubbing, and scraping;

2. site preparation activities, such as access roads, temporary fencing, trailer and utility installation, construction equipment installation and storage, equipment and supply laydown areas, borrow and fill sites, temporary parking facilities, and chemical spraying and controlled burns; and,

3. permanent installation activities for all facility and linear structures, including access roads, fencing (including tortoise fencing), utilities, parking facilities, equipment storage, mitigation and landscaping activities, and other installations, as applicable.

System Commissioning and Decommissioning

Commissioning activities are designed to test the functionality of a facility's installed components and systems to ensure safe and reliable operation. Although decommissioning is often synonymous with facility closure, specific decommissioning activities also systematically test the removal of such systems to ensure a facility's safe closure. For compliance monitoring purposes, commissioning examples include interface connection and utility pre-testing, "cold" and "hot" electrical testing, system pressurization and optimization tests, grid synchronization, and combustion turbine "first fire." Decommissioning activity examples include utility shut down, system depressurization and de-electrification, structure removal, and site reclamation.

Start of Commercial Operation

For compliance monitoring purposes, "commercial operation" or "operation" begins once commissioning activities are complete, the certificate of occupancy has been issued, and the power plant has reached reliable steady-state electrical production. At the start of commercial operation, plant control is usually transferred from the construction manager to the plant operations manager. Operation activities can include a steady state of electrical production, or, for "peaker plants," a seasonal or on-demand operational regime to meet peak load demands.

Non-Operation and Closure

Non-operation is time-limited and can encompass part or all of a facility. Non-operation can be a planned event, usually for minor equipment maintenance or repair, or unplanned, usually the result of unanticipated events or emergencies.

Closure is a facility shutdown with no intent to restart operation. It may also be the cumulative result of unsuccessful efforts to re-start over an increasingly lengthy period of non-operation, condemned by inadequate means and/or lack of a viable plan. Facility closures can occur due to a variety of factors, including, but not limited to, irreparable damage and/or functional or economic obsolescence.

ROLES AND RESPONSIBILITIES

Provided below is a generalized description of the compliance roles and responsibilities for Energy Commission staff (staff) and the project owner for the construction and operation of the PSEGS:

COMPLIANCE PROJECT MANAGER RESPONSIBILITIES

The CPM's compliance monitoring and project oversight responsibilities include:

1. ensuring that the design, construction, operation, and closure of the project facilities are in compliance with the terms and conditions of the Decision;

2. resolving complaints;

3. processing post-certification project amendments for changes to the project description, conditions of certification, ownership or operational control, and requests for extension of the deadline for the start of construction (see **COM-10** for instructions on filing a Petition to Amend or to extend construction start date);

4. documenting and tracking compliance filings; and,

5. ensuring that compliance files are maintained and accessible.

The CPM is the central contact person for the Energy Commission during project pre-construction, construction, operation, emergency response, and closure. The CPM will consult with the appropriate responsible parties when handling compliance issues, disputes, complaints, and amendments.

All project compliance submittals are submitted to the CPM for processing. Where a submittal requires CPM approval, the approval will involve appropriate Energy Commission technical staff and management. All submittals must include searchable electronic versions (.pdf, MS Word, or equivalent files).

Pre-Construction and Pre-Operation Compliance Meeting

The CPM usually schedules pre-construction and pre-operation compliance meetings prior to the projected start-dates of construction, plant operation, or both. These meetings are used to assist the Energy Commission and the project owner's technical staff in the status review of all required pre-construction or pre-operation conditions of certification, and take proper action if outstanding conditions remain. In addition, these meetings ensure, to the extent possible, that the Energy Commission's conditions of certification do not delay the construction and operation of the plant due to last-minute unforeseen issues or a compliance oversight. Pre-construction meetings held during the certification process must be publicly noticed unless they are confined to administrative issues and processes.

Energy Commission Record

The Energy Commission maintains the following documents and information as public records, in either the Compliance files or Dockets files, for the life of the project (or other period as specified):

1. all documents demonstrating compliance with any legal requirements relating to the construction, operation, and closure of the facility;

2. all Monthly and Annual Compliance Reports (MCRs, ACRs) filed by the project owner;

3. all project-related complaints of alleged noncompliance filed with the Energy Commission; and,

4. all petitions for project or condition of certification changes and the resulting staff or Energy Commission action.

CHIEF BUILDING OFFICIAL DELEGATION AND AGENCY COOPERATION

Under the California Building Code Standards, while monitoring project construction and operation, staff acts as, and has the authority of, the Chief Building Official (CBO). Staff may delegate CBO responsibility to either an independent third-party contractor or a local building official. However, staff retains CBO authority when selecting a delegate CBO, including the interpretation and enforcement of state and local codes, and the use of discretion, as necessary, in implementing the various codes and standards. The delegate CBO will also be responsible to facilitate compliance with all environmental Conditions of Certification, including Cultural Resources, and the implementation of all appropriate codes and standards and Energy Commission requirements. The CBO shall conduct on-site (including linear facilities) reviews and inspections at intervals necessary to fulfill those responsibilities. The project owner will pay a delegate CBO fees necessary to cover the costs of these reviews and inspections

PROJECT OWNER RESPONSIBILITIES

The project owner is responsible for ensuring that all conditions of certification in the PSEGS Decision are satisfied. The project owner will submit all compliance submittals to the CPM for processing unless the conditions specify another recipient. The **Compliance** Conditions regarding post-certification changes specify measures that the project owner must take when modifying the project's design, operation, or performance requirements, or to transfer ownership or operational control. Failure to comply with any of the conditions of certification may result in a correction order, an administrative fine, certification revocation, or any combination thereof, as appropriate. A summary of the **Compliance** Conditions of Certification is included as **Compliance Table 1** at the end of this Compliance Plan.

COMPLIANCE ENFORCEMENT

The Energy Commission's legal authority to enforce the terms and conditions of its Decision are specified in Public Resources Code sections 25534 and 25900. The Energy Commission may amend or revoke a project certification and may impose a civil penalty for any significant failure to comply with the terms or conditions of the Decision. The Energy Commission's actions and fine assessments would take into account the specific circumstances of the incident(s).

PERIODIC COMPLIANCE REPORTING

Many of the conditions of certification require submittals in the MCRs and ACRs. All compliance submittals assist the CPM in tracking project activities and monitoring compliance with the terms and conditions of the PSEGS Decision. During construction, the project owner or an authorized agent will submit compliance reports on a monthly basis. During operation, compliance reports are submitted annually. These reports and the requirements for an accompanying compliance matrix are described below.

NONCOMPLIANCE COMPLAINT PROCEDURES

Any person or agency may file a complaint alleging noncompliance with the conditions of certification. Such a complaint will be subject to review by the Energy Commission pursuant to Title 20, California Code of Regulations, section 1237, but, in many instances, the issue(s) can be resolved by using an informal dispute resolution process. Both the informal and formal complaint procedures, as described in current state law and regulations, are summarized below. Energy Commission staff will follow these provisions unless superseded by future law or regulations. The California Office of Administrative Law provides on-line access to the California Code of Regulations at http://www.oal.ca.gov/.

Informal Dispute Resolution Process

The following informal procedure is designed to resolve code and compliance interpretation disputes stemming from the project's conditions of certification and other LORS. The project owner, the Energy Commission, or any other party, including members of the public, may initiate the informal dispute resolution process. Disputes may pertain to actions or decisions made by any party, including the Energy Commission's delegate agents.

This process may precede the formal complaint and investigation procedure specified in Title 20, California Code of Regulations, section 1237, but is not intended to be a prerequisite or substitute for it. This informal procedure may not be used to change the terms and conditions of certification in the Decision, although the agreed-upon resolution may result in a project owner proposing an amendment. The informal dispute resolution process encourages all parties to openly discuss the conflict and reach a mutually agreeable solution. If a dispute cannot be resolved, then the matter must be brought before the full Energy Commission for consideration via the complaint and investigation procedure specified in Title 20, California Code of Regulations, section 1237.

Request for Informal Investigation

Any individual, group, or agency may request that the CPM conduct an informal investigation of alleged noncompliance with the Energy Commission's conditions of certification. Upon receipt of an informal investigation request, the CPM will promptly provide both verbal and written notification to the project owner of the allegation(s), along with all known and relevant information of the alleged noncompliance. The CPM will evaluate the request and, if the CPM determines that further investigation is necessary, will ask the project owner to promptly conduct a formal inquiry into the matter and provide within seven days a written report of the investigation results, along with corrective measures proposed or undertaken. Depending on the urgency of the matter, the CPM may conduct a site visit and/or request that the project owner provide an initial verbal report within 48 hours.

Request for Informal Meeting

In the event that either the requesting party or Energy Commission staff are not satisfied with the project owner's investigative report or corrective measures, either party may submit a written request to the CPM for a meeting with the project owner. The request shall be made within 14 days of the project owner's filing of the required investigative report. Upon receipt of such a request, the CPM will attempt to:

1. immediately schedule a meeting with the requesting party and the project owner, to be held at a mutually convenient time and place;

2. secure the attendance of appropriate Energy Commission staff and staff of any other agencies with expertise in the subject area of concern, as necessary; and

3. conduct the meeting in an informal and objective manner so as to encourage the voluntary settlement of the dispute in a fair and equitable manner.

After the meeting, the CPM will promptly prepare and distribute copies to all parties, and to the project file, of a summary memorandum that fairly and accurately identifies the positions of all parties and any understandings reached. If no agreement was reached, the CPM will direct the complainant to the formal complaint process provided under Title 20, California Code of Regulations, section 1237.

Formal Dispute Resolution Procedure

Any person may file a complaint with the Energy Commission's Dockets Unit alleging noncompliance with a Commission Decision adopted pursuant to Public Resources Code section 25500. Requirements for complaint filings and a description of how complaints are processed are in Title 20, California Code of Regulations, section 1237.

POST-CERTIFICATION CHANGES TO THE ENERGY COMMISSION DECISION

The project owner must petition the Energy Commission pursuant to Title 20, California Code of Regulations, section 1769, to modify the design, operation, or performance requirements of the project and/or the linear facilities, or to transfer ownership or operational control of the facility. **It is the responsibility of the project owner to contact the CPM to determine if a proposed project change should be considered a project modification pursuant to section 1769.** Implementation of a project modification without first securing Energy Commission approval may result in an enforcement action including civil penalties in accordance with Public Resources Code, section 25534.

Below is a summary of the criteria for determining the type of approval process required, and reflects the provisions of Title 20, California Code of Regulations, section 1769, at the time this Compliance Plan was drafted. If the Energy Commission modifies this regulation, the language in effect at the time of the requested change shall apply. Upon request, the CPM can provide sample formats of these submittals.

Amendment

The project owner shall submit a Petition to Amend the Energy Commission Decision, pursuant to Title 20, California Code of Regulations, section 1769 (a), when proposing modifications to the design, operation, or performance requirements of the project and/or the linear facilities. If a proposed modification results in an added, changed, or deleted condition of certification, or makes changes causing noncompliance with any applicable LORS, the petition will be processed as a formal amendment to the Decision, triggering public notification of the proposal, public review of the Energy Commission staff's analysis, and approval by the full Energy Commission.

Change of Ownership and/or Operational Control

Change of ownership or operational control also requires that the project owner file a petition pursuant to section 1769 (b). This process requires public notice and approval by the full Commission. The petition shall be in the form of a legal brief and fulfill the requirements of section 1769 (b).

Staff-Approved Project Modification

Modifications that do not result in additions, deletions, or changes to the conditions of certification, that are compliant with the applicable LORS, and that will not have significant environmental impacts, may be authorized by the CPM as a staff-approved project modification pursuant to section 1769 (a) (2). Once the CPM files a Notice of Determination of the proposed project modifications, any person may file an objection to the CPM's determination within 14 days of service on the grounds that the modification does not meet the criteria of section 1769 (a) (2). If there is a valid objection to the CPM's determination, the petition must be processed as a formal amendment to the Decision and must be considered for approval by the full Commission at a publically noticed Business Meeting or hearing.

Verification Change

Each condition of certification (except for the **Compliance** Conditions) has one or more means of verifying the project owner's compliance with the provisions of the condition. These verifications specify the actions and deadlines by which a project owner demonstrates compliance with the Energy Commission-adopted conditions. A verification may be modified by the CPM without requesting a Decision amendment if the change does not conflict with any condition of certification, does not violate any LORS, and provides an effective alternative means of verification.

EMERGENCY RESPONSE CONTINGENCY PLANNING AND INCIDENT REPORTING

To protect public health and safety and environmental quality, the conditions of certification include contingency planning and incident reporting requirements to ensure compliance with necessary health and safety practices. A well-drafted contingency plan avoids or limits potential hazards and impacts resulting from serious incidents involving personal injury, hazardous spills, flood, fire, explosions or other catastrophic events and ensures a comprehensive timely response. All such incidents must be reported immediately to the CPM and documented. These requirements are designed to build from "lessons learned" limit the hazards and impacts, anticipate and prevent recurrence, and provide for the safe and secure shutdown and re-start of the facility.

FACILITY CLOSURE

The Energy Commission cannot reasonably foresee all potential circumstances in existence when a facility permanently closes. Therefore, the closure conditions provided herein strive for the flexibility to address circumstances that may exist at some future time. Most importantly, facility closure must be consistent with all applicable Energy Commission conditions of certification and the LORS in effect at that time.

Although a non-operational facility may intend to resume operations, if it remains non-operational for longer than one year and the project owner does not present a viable plan to resume operation, the Energy Commission can conclude that closure is imminent and direct the project owner to commence closure procedures under the jurisdiction and guidance of the Bureau of Land Management.

Prior to submittal of the facility's Final Closure Plan to the Energy Commission, the project owner and the CPM will hold a meeting to discuss the specific contents of the plan. In the event that significant issues are associated with the plan's approval, the CPM will hold one or more workshops and/or the Commission may hold public hearings as part of its approval procedure.

With the exception of measures to eliminate any immediate threats to public health and safety or to the environment, facility closure activities cannot be initiated until the Energy Commission approves the Final Closure Plan and Cost Estimate and the project owner complies with any requirements the Commission may incorporate as conditions of approval of the Final Closure Plan.

COMPLIANCE CONDITIONS OF CERTIFICATION

Staff has proposed modifications to the **Compliance** Conditions of Certification as shown below. Deleted text is in ~~strikethrough~~. New text is **bold** and **underlined**. New text that should remain bold in the final Decision is in *italics*. New text that should remain underlined in the final Decision is double-underlined.

COM-1: **Unrestricted Access**~~Compliance-1~~. The project owner shall take all steps necessary to ensure that the CPM, responsible Energy Commission staff, and delegate agencies or consultants have unrestricted access to the facility site, related facilities, project-related staff, and the records maintained on-site to facilitate audits, surveys, inspections, and general or closure-related site visits. Although the CPM will normally schedule site visits on dates and times agreeable to the project owner, the CPM reserves the right to make unannounced visits at any time, whether such visits are by the CPM in person or through representatives from Energy Commission staff, delegate agencies, or consultants. ~~The CPM, responsible Energy Commission staff, and delegated agencies or consultants shall be guaranteed and granted unrestricted access to the power plant site, related facilities, project-related staff, and the records maintained on-site for the purpose of conducting audits, surveys, inspections, or general site visits. Although the CPM will normally schedule site visits on dates and times agreeable to the project owner, the CPM reserves the right to make unannounced visits at any time.~~

COM-2: **Compliance Record**~~Compliance-2~~. The project owner shall maintain electronic copies of all project files and submittals on-site, or at an alternative site approved by the CPM, for the operational life and closure of the project. The files shall also contain at least one hard copy of:

1. **the facility's Application for Certification;**
2. **all amendment petitions and Energy Commission orders;**
3. **all finalized original and amended structural plans and "as-built" drawings for the entire project;**
4. **all citations, warnings, violations, or corrective actions applicable to the project; and,**
5. **the most current versions of any plans, manuals, and training documentation required by the conditions of certification or applicable LORS.**

Energy Commission staff and delegate agencies shall, upon request to the project owner, be given unrestricted access to the files maintained pursuant to this condition. ~~The project owner shall maintain project files on-site or at an alternative site approved by the CPM for the life of the project, unless a lesser period of time is specified by the conditions of certification. The~~

~~files shall contain copies of all "as-built" drawings, documents submitted as verification for conditions, and other project-related documents.~~

~~Energy Commission staff and delegate agencies shall, upon request to the project owner, be given unrestricted access to the files maintained pursuant to this condition.~~

COM-3: Compliance Verification Submittals~~Compliance-3~~. Verification lead times associated with the start of construction or closure may require the project owner to file submittals during the AFC process, particularly if construction is planned to commence shortly after certification. The verification procedures, unlike the conditions, may be modified as necessary by the CPM.

A cover letter from the project owner or an authorized agent is required for all compliance submittals and correspondence pertaining to compliance matters. *The cover letter subject line shall identify the project by AFC number, cite the appropriate condition of certification number(s), and give a brief description of the subject of the submittal.* When submitting supplementary or corrected information, the project owner shall reference the date of the previous submittal and the condition(s) of certification applicable.

All reports and plans required by the project's conditions of certification shall be submitted in a searchable electronic format (.pdf, MS Word or Excel, etc.) and include standard formatting elements such as a table of contents, identifying by title and page number, each section, table, graphic, exhibit, or addendum. All report and/or plan graphics and maps shall be adequately scaled and shall include a key with descriptive labels, directional headings, a bar scale, and the most recent revision date.

The project owner is responsible for the content and delivery of all verification submittals to the CPM, whether the actions required by the verification were satisfied by the project owner or an agent of the project owner. All submittals shall be accompanied by an electronic copy on an electronic storage medium, or by e-mail, as agreed upon by the CPM. If hardcopy submittals are required, please address as follows:

Christine Stora, Compliance Project Manager
Palen Solar Electric Generating System (09-AFC-7C)
California Energy Commission
1516 Ninth Street (MS-2000)
Sacramento, CA 95814

~~Each condition of certification is followed by a means of verification. The verification describes the Energy Commission's procedure(s) to ensure post-certification compliance with adopted conditions. The verification procedures, unlike the Conditions, may be modified as necessary by the CPM.~~

~~Verification of compliance with the conditions of certification can be accomplished by the following:~~

1. ~~monthly and/or annual compliance reports, filed by the project owner or authorized agent, reporting on work done and providing pertinent documentation, as required by the specific conditions of certification;~~

2. ~~appropriate letters from delegate agencies verifying compliance;~~

3. ~~Energy Commission staff audits of project records; and/or~~

4. ~~Energy Commission staff inspections of work, or other evidence that the requirements are satisfied.~~

~~Verification lead times associated with start of construction may require the project owner to file submittals during the certification process, particularly if construction is planned to commence shortly after certification.~~

~~A cover letter from the project owner or authorized agent is required for all compliance submittals and correspondence pertaining to compliance matters.~~ **~~The cover letter subject line shall identify the project by AFC number, the appropriate condition(s) of certification by condition number(s), and a brief description of the subject of the submittal~~**~~. The project owner shall also identify those submittals~~ **~~not~~** ~~required by a condition of certification with a statement such as: "This submittal is for information only and is~~ **~~not~~** ~~required by a specific condition of certification." When submitting supplementary or corrected information, the project owner shall reference the date of the previous submittal and Energy Commission submittal number.~~

~~The project owner is responsible for the delivery and content of all verification submittals to the CPM, whether such condition was satisfied by work performed by the project owner or an agent of the project owner.~~

~~All hardcopy submittals shall be addressed as follows:~~

~~Dale Rundquist~~
~~Compliance Project Manager~~
~~(09-AFC-7C)~~
~~California Energy Commission~~
~~1516 Ninth Street (MS-2000)~~
~~Sacramento, CA 95814~~

~~Those submittals shall be accompanied by a searchable electronic copy, on a CD or by e-mail, as agreed upon by the CPM.~~

~~If the project owner desires Energy Commission staff action by a specific date, that request shall be made in the submittal cover letter and shall include a detailed explanation of the effects on the project if that date is not met.~~

COM-4: Pre-Construction Matrix and Tasks Prior to Start of Construction~~Compliance-4~~. Prior to start of construction, the project owner shall submit to the CPM a compliance matrix including **only** those conditions that must be fulfilled before the start of construction. The matrix shall be included with the project owner's first compliance submittal or prior to the first pre-construction meeting, whichever comes first~~. It will~~ , and shall be submitted in a format similar to ~~the description~~that described below.

~~Construction shall not commence until the pre-construction matrix is submitted, all pre-construction conditions have been complied with, and the CPM has issued a letter to the project owner authorizing construction. Various lead times for submittal of compliance verification documents to the CPM for Conditions of Certification are established to allow sufficient Staff time to review and comment and, if necessary, allow the project owner to revise the submittal in a timely manner. This will ensure that project construction may proceed according to schedule.~~

Site mobilization and construction activities shall not start until all of the following occur: the project owner has submitted the pre-construction matrix and compliance verifications pertaining to all pre-construction conditions of certification; and the CPM has issued an authorization-to-construct letter to the project owner. The deadlines for submitting various compliance verifications to the CPM allow sufficient staff time to review and comment on, and if necessary, allow the project owner to revise the submittal in a timely manner. These procedures help ensure that project construction proceeds according to schedule. Failure to submit required compliance documents by the specified deadlines may result in delayed authorizations to commence various stages of the project.

~~Failure to submit compliance documents within the specified lead time may result in delays in authorization to commence various stages of the project.~~

~~If the project owner anticipates commencing project construction as soon as the project is certified,~~ **If the project owner anticipates site mobilization immediately following project certification,** it may be necessary for the project owner to file compliance submittals prior to project certification. **In these instances, compliance verifications can be submitted in advance of the required deadlines and the anticipated authorizations to start construction. The project owner must understand that submitting compliance verifications prior to these authorizations is at the owner's own risk. Any approval by Energy Commission staff prior to project certification is subject to change based upon the Commission Decision, or amendment thereto, and early staff compliance approvals do not imply that the Energy Commission will certify the project for actual construction and operation.** ~~Compliance submittals should be completed in advance where the necessary lead time for a required compliance event extends beyond the~~

~~date anticipated for start of construction. The project owner must understand that the submittal of compliance documents prior to project certification is at the owner's own risk. Any approval by Energy Commission staff is subject to change, based upon the Commission Decision.~~

~~**Compliance Reporting**~~

~~There are two different compliance reports that the project owner must submit to assist the CPM in tracking activities and monitoring compliance with the terms and conditions of the Energy Commission Decision. During construction, the project owner or authorized agent will submit Monthly Compliance Reports. During operation, an Annual Compliance Report must be submitted. These reports, and the requirement for an accompanying compliance matrix, are described below. The majority of the conditions of certification require that compliance submittals be submitted to the CPM in the monthly or annual compliance reports.~~

COM-5: **Compliance Matrix**~~Compliance-5~~. ~~A compliance matrix shall be submitted by the project owner to the CPM along with each~~ The project owner shall submit a compliance matrix to the CPM with each ~~Monthly and Annual Compliance Report~~MCR and ACR. The compliance matrix ~~is intended to~~ provides the CPM with the ~~current~~ status of all conditions of certification in a spreadsheet format. The compliance matrix shall identify:

1. the technical area;
2. the condition number;
3. a brief description of the verification action or submittal required by the condition;
4. the date the submittal is required (e.g., 60 days prior to construction, after final inspection, etc.);
5. the expected or actual submittal date;
6. the date a submittal or action was approved by the CBO, CPM, or delegate agency, if applicable;
7. the compliance status of each condition, e.g., "not started," "in progress," or "completed" (include the date); and
8. if the condition was amended, **the updated language and the date the amendment was proposed or approved.** ~~the date of the amendment.~~

The CPM can provide a template for the compliance matrix upon request. ~~Satisfied conditions shall be placed at the end of the matrix.~~

COM-6: Monthly Compliance Reports and Key Events List~~Compliance-6~~. The first ~~Monthly Compliance Report~~ MCR is due one (1) month following the ~~Energy Commission business meeting date upon which the project was approved, the~~ docketing of the project's Decision, unless otherwise agreed to by the CPM. The first ~~Monthly Compliance Report~~ MCR shall include the AFC number and an initial list of dates for each of the events identified on the Key Events List ~~found at the end of this section of the Decision~~. (The Key Events List form is found at the end of this Compliance Plan.)

During **project** pre-construction**,** ~~and~~ construction**, or closure** ~~of the project~~, the project owner or authorized agent shall submit an ~~original and an~~ electronic searchable version of the ~~Monthly Compliance Report~~ **MCR** within ten (10) **business** days after the end of each reporting month, unless otherwise specified by the CPM. ~~Monthly Compliance Reports~~ **MCRs** shall be clearly identified for the month being reported. The searchable electronic copy may be filed on an electronic storage medium or by e-mail, subject to CPM approval. The compliance verification submittal condition provides guidance on report production standards, and the ~~Monthly Compliance Report~~ **MCR** shall contain, at a minimum:

1. a summary of the current project construction status, a revised/updated schedule if there are significant delays, and an explanation of any significant changes to the schedule;

2. documents required by specific conditions to be submitted along with the ~~Monthly Compliance Report~~ **MCR**~~.~~**;** ~~E~~**e**ach of these items shall be identified in the transmittal letter, as well as the conditions they satisfy**,** and submitted as attachments to the ~~Monthly Compliance Report~~ **MCR**;

3. an initial, and thereafter updated, compliance matrix showing the status of all conditions of certification;

4. a list of conditions that have been satisfied during the reporting period, and a description or reference to the actions that satisfied the condition;

5. a list of any submittal deadlines that were missed, accompanied by an explanation and an estimate of when the information will be provided;

6. a cumulative list~~ing~~ of any approved changes to **the** conditions of certification;

7. a list~~ing~~ of any filings submitted to, ~~or~~**and** permits issued by, other governmental agencies during the month;

8. a projection of project compliance activities scheduled during the next two months**;** ~~T~~**t**he project owner shall notify the CPM as soon as any changes are made to the project construction schedule that would affect compliance with conditions of certification;

9. a list~~ing~~ of the month's additions to the on-site compliance file; and

10. a list~~ing~~ of complaints, notices of violation, official warnings, and citations received during the month, a description of the **actions taken to date to resolve** ~~resolution of the resolved actions,~~ **the issues**; and the status of any unresolved actions.

~~All sections, exhibits, or addendums shall be separated by tabbed dividers or as acceptable by the CPM.~~

COM-7: **Annual Compliance Reports**~~Compliance-7~~. After construction is complete, the project owner shall submit searchable electronic ~~Annual Compliance Reports~~ACRs instead of ~~Monthly Compliance Reports~~MCRs. ~~The~~ ACRs ~~reports are~~ shall be completed for each year of commercial operation, may be required for a specified period after decommissioning to monitor closure compliance, as specified by the CPM, and are due ~~to the CPM~~ each year on a date agreed to by the CPM. ~~Annual Compliance Reports shall be submitted over the life of the project, unless otherwise specified by the CPM.~~ The searchable electronic ~~copy~~copies may be filed on an electronic storage medium or by e-mail, subject to CPM approval. Each ~~Annual Compliance Report~~ ACR shall include the AFC number, identify the reporting period, and ~~shall~~ contain the following:

1. an updated compliance matrix showing the status of all conditions of certification (fully satisfied conditions do not need to be included in the matrix after they have been reported as completed);

2. a summary of the current project operating status and an explanation of any significant changes to facility operations during the year;

3. documents required by specific conditions to be submitted along with the ~~Annual Compliance Report~~ **ACR**. Each of these items shall be identified in the transmittal letter with the condition it satisfies, and submitted as attachments to the ~~Annual Compliance Report~~ **ACR**;

4. a cumulative list~~ing~~ of all post-certification changes approved by the Energy Commission or ~~cleared by~~ the CPM;

5. an explanation for any submittal deadlines that were missed, accompanied by an estimate of when the information will be provided;

6. a list~~ing~~ of filings submitted to, or permits issued by, other governmental agencies during the year;

7. a projection of project compliance activities scheduled during the next year;

8. a list~~ing~~ of the year's additions to the on-site compliance file;

9. an evaluation of the ~~on-site~~ **Site Contingency Plan, including amendments and plan updates** ~~contingency plan for unplanned facility closure, including any suggestions necessary for bringing the plan up to date (see Compliance Conditions for Facility Closure addressed later in this section)~~; and

10. a list~~ing~~ of complaints, notices of violation, official warnings, and citations received during the year, a description of **how the issues were resolved**~~the resolution of any resolved matters~~, and the status of any unresolved matters.

COM-8: Confidential Information~~Compliance-8~~. Any information that the project owner ~~deems~~designates as confidential shall be submitted to the Energy Commission's Executive Director with an application for confidentiality, pursuant to Title 20, California Code of Regulations, section 2505 (a). Any information ~~that is determined to be confidential shall be kept confidential~~ deemed confidential pursuant to the regulations will remain undisclosed, as provided ~~for~~ in Title 20, California Code of Regulations, section 2501~~, et. seq~~.

COM-9: Annual Energy Facility Compliance Fee. Pursuant to the provisions of section 25806 (b) of the Public Resources Code, the project owner is required to pay an annually adjusted compliance fee. Current compliance fee information is available on the Energy Commission's website at http://www.energy.ca.gov/siting/filing_fees.html. The project owner may also contact the CPM for the current fee information. The initial payment is due on the date the Energy Commission dockets its final Decision. All subsequent payments are due by July 1 of each year in which the facility retains its certification.

COM-10: Amendments, Staff-Approved Project Modifications, Ownership Changes, and Verification Changes. The project owner shall petition the Energy Commission, pursuant to Title 20, California Code of Regulations, section 1769, to modify the design, operation, or performance requirements of the project or linear facilities, or to transfer ownership or operational control of the facility. The CPM will determine whether staff approval will be sufficient or whether Commission approval will be necessary. ~~based upon whether or not the proposed amendment(s) result in changed, added, or deleted conditions of certification or the changes cause noncompliance with any applicable LORS.~~ **It is the project owner's responsibility to contact the CPM to determine if a proposed project change triggers the requirements of section 1769.** Section 1769 details the required contents for a Petition to Amend an Energy Commission Decision. The only change that can be requested by means of a letter to the CPM is a request to change the verification method of a condition of certification.

Implementation of a project modification without first securing Energy Commission, or Energy Commission staff approval, may result in an enforcement action, including civil penalties, in accordance with section 25534 of the Public Resources Code. If the Energy Commission's rules

regarding amendments are revised, the rules in effect at the time the change is requested shall apply.

COM-11: Reporting of Complaints, Notices, and Citations~~Compliance 9~~. Prior to the start of construction or decommissioning, the project owner shall send a letter to property owners within one (1) mile of the project, notifying them of a telephone number to contact project representatives with questions, complaints, or concerns. If the telephone is not staffed twenty-four (24) hours per day, it shall include automatic answering with a date and time stamp recording.

The project owner shall respond to all recorded complaints within twenty-four (24) hours or the next business day. The project site shall post the telephone number on-site and make it easily visible to passersby during construction, operation, and closure. The project owner shall provide the contact information to the CPM who will post it on the Energy Commission's web page at http://www.energy.ca.gov/sitingcases/palen/. The project owner shall report any disruption to the contact system or telephone number change to the CPM promptly, to allow the CPM to update the Energy Commission's facility webpage accordingly.

In addition to including all complaints, notices, and citations included with the MCRs and ACRs, within ten (10) days of receipt, the project owner shall report, and provide copies to the CPM, of all complaints, including noise and lighting complaints, notices of violation, notices of fines, official warnings, and citations. Complaints shall be logged and numbered. Noise complaints shall be recorded on the form provided in the *Noise and Vibration* Conditions of Certification. All other complaints shall be recorded on the complaint form (Attachment A) at the end of this Compliance Plan.

COM-12: Emergency Response Site Contingency Plan. No less than sixty (60) days prior to the start of commercial operation, or other date agreed to by the CPM, the project owner shall submit for CPM review and approval, *an Emergency Response* Site Contingency Plan (Contingency Plan). The Contingency Plan shall evidence a facility's coordinated emergency response and recovery preparedness for a series of reasonably foreseeable emergency events. The CPM may require the updating of the Contingency Plan over the life of the facility. Contingency Plan elements include, but are not limited to:

1. **a site-specific list and direct contact information for persons, agencies, and responders to be notified for an unanticipated event;**

2. **a detailed and labeled facility map, including all fences and gates, the windsock location (if applicable), the on- and off-site assembly areas, and the main roads and highways near the site;**

3. **a detailed and labeled map of population centers, sensitive receptors, and the nearest emergency response facilities;**

4. **a description of the on-site, first response and backup emergency alert and communication systems, site-specific emergency response protocols, and procedures for maintaining the facility's contingency response capabilities, including a detailed map of interior and exterior evacuation routes, and the planned location(s) of all permanent safety equipment;**

5. **an organizational chart including the name, contact information, and first aid/emergency response certification(s) and renewal date(s) for all personnel regularly on-site;**

6. **a brief description of reasonably foreseeable, site-specific incidents and accident sequences (on- and off-site), including response procedures and protocols and site security measures to maintain twenty-four-hour site security;**

7. **procedures for maintaining contingency response capabilities; and**

8. **the procedures and implementation sequence for the safe and secure shutdown of all non-critical equipment and removal of hazardous materials and waste (see also specific conditions of certification for the technical areas of *Public Health, Solid Waste Management, Hazardous Materials Management*, and *Worker Safety*).**

COM-13: Incident-Reporting Requirements. Within one (1) hour, the project owner shall notify the CPM or Compliance Office Manager, by telephone and e-mail, of any incident at the power plant or appurtenant facilities that results or could result in any of the following:

1. **reduction in the facility's ability to respond to dispatch (excluding forced outages caused by protective equipment or other typically encountered shutdown events);**

2. **health and safety impacts on the surrounding population;**

3. **property damage off-site;**

4. **response by off-site emergency response agencies;**

5. **serious on-site injury;**

6. **serious environmental damage; or**

7. **emergency reporting to any federal, state, or local agency.**

The notice shall describe the circumstances, status, and expected duration of the incident.

If warranted, as soon as it is safe and feasible, the project owner shall implement the safe shutdown of any non-critical equipment and removal of any hazardous materials and waste that pose a threat to public health and safety and to environmental quality (also, see specific conditions of certification for the technical areas of *Hazardous Materials Management* and *Solid Waste Management*).

Within one (1) week ~~of the occurrence~~ of the incident, the project owner shall submit to the CPM a detailed incident report, which shall include, as appropriate ~~to the incident~~, the following information:

1. **a brief description of the incident, including its date, time, and location;**
2. **a description of the cause of the incident, or likely causes if it is still under investigation;**
3. **the location of any off-site impacts;**
4. **description of any resultant impacts;**
5. **a description of emergency response actions associated with the incident;**
6. **identification of responding agencies;**
7. **identification of emergency notifications made to ~~other~~ federal, state, and/or local agencies;**
8. **identification of any hazardous materials released and an estimate of the quantity released;**
9. **a description of any injuries, fatalities, or property damage that occurred as a result of the incident;**
10. **fines or violations assessed or being processed by other agencies;**
11. **name, phone number, and e-mail address of the appropriate facility contact person having knowledge of the event; and**
12. **corrective actions to prevent a recurrence of the incident.**

The project owner shall maintain all incident report records for the life of the project, including closure. After the submittal of the initial report for any incident, the project owner shall submit to the CPM copies of incident reports within twenty-four (24) hours of a request.

COM-14: Non-Operation. If the facility ceases operation temporarily, either planned or unplanned, for longer than one (1) week (or other CPM-approved date), but less than three (3) months (or other CPM-approved date), the project owner shall notify the CPM, interested agencies, and nearby property owners. Notice of planned non-operation shall be given at least two (2) weeks prior to the scheduled date. Notice of unplanned non-operation shall be provided no later than one (1) week after non-operation begins.

For any non-operation, a Repair/Restoration Plan for conducting the activities necessary to restore the facility to availability and reliable and/or improved performance shall be submitted to the CPM within one (1) week after notice of non-operation is given. If non-operation is due to an unplanned incident, temporary repairs and/or corrective actions may be undertaken before the Repair/Restoration Plan is submitted. The Repair/Restoration Plan shall include:

1. **identification of operational and non-operational components of the plant;**
2. **a detailed description of the repair or restoration activities;**
3. **a proposed schedule for completing the repair or restoration activities;**
4. **an assessment of whether or not the proposed activities would require changing, adding, and/or deleting any conditions of certification and/or would cause noncompliance with any applicable LORS; and**
5. **planned activities during non-operation, including any measures to ensure continued compliance with all conditions of certification and LORS.**

Written updates to the CPM for non-operational periods, until operation resumes, shall include:

1. **progress relative to the schedule;**
2. **developments that delayed or advanced progress or that may delay or advance future progress;**
3. **any public, agency, or media comments or complaints; and**
4. **projected date for the resumption of operation.**

During non-operation, all applicable conditions of certification and reporting requirements remain in effect. If, after one (1) year from the date of the project owner's last report of productive Repair/Restoration Plan work, the facility does not resume operation or does not provide a plan to resume operation, the Executive Director may assign suspended status to the facility and recommend commencement of permanent closure activities.

1. **If the facility has a closure plan, the project owner shall update it and submit it for Energy Commission review and approval.**

2. **If the facility does not have a closure plan, the project owner shall develop one consistent with the requirements in this Compliance Plan and submit it for Energy Commission review and approval.**

COM-15: Facility Closure Planning. **To ensure that a facility's eventual permanent closure and long-term maintenance do not pose a threat to public health and safety and/or to environmental quality, the project owner shall coordinate with the Energy Commission to plan and prepare for eventual permanent closure.**

A. Provisional Closure Plan and Estimate of Permanent Closure Costs

To assure satisfactory long-term site maintenance and adequate closure for "the whole of a project," the project owner shall submit a Provisional Closure Plan and Cost Estimate for CPM review and approval within sixty (60) days after the start of commercial operation. The Provisional Closure Plan and Cost Estimate shall consider applicable final closure plan requirements, including interim and long-term, post-closure site maintenance costs, and reflect:

1. **facility closure costs at a time in the facility's projected life span when the mode and scope of facility operation would make permanent closure the most expensive;**

2. **the use of an independent third party to carry out the permanent closure; and**

3. **no use of salvage value to offset closure costs.**

The Provisional Closure Plan and Cost Estimate shall provide for a phased closure process and include but not be limited to:

1. **comprehensive scope of work and itemized budget;**
2. **closure plan development costs;**
3. **dismantling and demolition;**
4. **recycling and site clean-up;**
5. **mitigation and monitoring direct, indirect, and cumulative impacts;**
6. **site remediation and/or restoration;**

7. <u>interim operation and post-closure monitoring and maintenance, including long-term equipment replacement costs; and</u>

8. <u>contingencies.</u>

<u>The project owner shall include an updated Provisional Closure Plan and Cost Estimate in every fifth-year ACR for CPM review and approval. Each updated Provisional Closure Plan and Cost Estimate shall reflect the most current regulatory standards, best management practices, and applicable LORS.</u>

<u>B. Final Closure Plan and Cost Estimate</u>

<u>At least three (3) years prior to initiating a permanent facility closure, the project owner shall submit for Energy Commission review and approval, a Final Closure Plan and Cost Estimate, which includes any long-term, post-closure site maintenance and monitoring. Final Closure Plan and Cost Estimate contents include, but are not limited to:</u>

1. <u>a statement of specific Final Closure Plan objectives;</u>

2. <u>a statement of qualifications and resumes of the technical experts proposed to conduct the closure activities, with detailed descriptions of previous power plant closure experience;</u>

3. <u>identification of any facility-related installations not part of the Energy Commission certification, designation of who is responsible for these, and an explanation of what will be done with them after closure;</u>

4. <u>a comprehensive scope of work and itemized budget for permanent plant closure and long-term site maintenance activities, with a description and explanation of methods to be used, broken down by phases, including, but not limited to:</u>

    a. <u>dismantling and demolition;</u>

    b. <u>recycling and site clean-up;</u>

    c. <u>impact mitigation and monitoring;</u>

    d. <u>site remediation and/or restoration;</u>

    e. <u>post-closure maintenance; and</u>

    f. <u>contingencies.</u>

5. <u>a revised/updated Final Cost Estimate for all closure activities, by phases, including long-term, post-closure site monitoring and maintenance costs, and replacement of long-term post-closure equipment;</u>

6. <u>a schedule projecting all phases of closure activities for the power plant site and all appurtenances constructed as part of the Energy Commission-certified project;</u>

7. <u>an electronic submittal package of all relevant plans, drawings, risk assessments, and maintenance schedules and/or reports, including an above- and below-ground infrastructure inventory map and registered engineer's or delegate CBO's assessment of demolishing the facility; additionally, for any facility that permanently ceased operation prior to submitting a Final Closure Plan and Cost Estimate and for which only minimal or no maintenance has been done since, a comprehensive condition report focused on identifying potential hazards;</u>

8. <u>all information additionally required by the facility's conditions of certification applicable to plant closure;</u>

9. <u>an equipment disposition plan, including:</u>

a. <u>recycling and disposal methods for equipment and materials; and</u>

b. <u>identification and justification for any equipment and materials that will remain on-site after closure;</u>

10. <u>a site disposition plan, including but not limited to:</u>

    a. <u>proposed rehabilitation, restoration, and/or remediation procedures, as required by the conditions of certification and applicable LORS,</u>

    b. <u>long-term site maintenance activities, and</u>

    c. <u>anticipated future land-use options after closure;</u>

11. <u>identification and assessment of all potential direct, indirect, and cumulative impacts and proposal of mitigation measures to reduce significant adverse impacts to a less-than-significant level; potential impacts to be considered shall include, but not be limited to:</u>

    a. <u>traffic</u>

    b. <u>noise and vibration</u>

    c. <u>soil erosion</u>

    d. <u>air quality degradation</u>

    e. <u>solid waste</u>

    f. <u>hazardous materials</u>

    g. <u>waste water discharges</u>

h. contaminated soil

12. identification of all current conditions of certification, LORS, federal, state, regional, and local planning efforts applicable to the facility, and proposed strategies for achieving and maintaining compliance during closure;

13. updated mailing list or listserv of all responsible agencies, potentially interested parties, and property owners within one (1) mile of the facility;

14. identification of alternatives to plant closure and assessment of the feasibility and environmental impacts of these; and

15. description of and schedule for security measures and safe shutdown of all non-critical equipment and removal of hazardous materials and waste (see conditions of certification for *Public Health*, *Solid Waste Management*, *Hazardous Materials Management*, and *Worker Safety*).

If an Energy Commission-approved Final Closure Plan and Cost Estimate is not implemented within one (1) year of its approval date, it shall be updated and re-submitted to the Commission for supplementary review and approval. If a project owner initiates but then suspends closure activities, and the suspension continues for longer than one (1) year, or subsequently abandons the facility, the Energy Commission may access the required financial assurance funds to complete the closure. The project owner remains liable for all costs of contingency planning and closure.

~~PLANNED CLOSURE (COMPLIANCE-10)~~

~~In order to ensure that a planned facility closure does not create adverse impacts, a closure process that provides for careful consideration of available options and applicable laws, ordinances, regulations, standards, and local/regional plans in existence at the time of closure will be undertaken. To ensure adequate review of a planned project closure, the project owner shall submit a proposed facility closure plan to the Energy Commission for review and approval at least 12 months (or other period of time agreed to by the CPM) prior to the commencement of closure activities. The project owner shall file 120 copies (or other number of copies agreed upon by the CPM) of a proposed facility closure plan with the Energy Commission.~~

~~The plan shall:~~

1. ~~identify and discuss any impacts and mitigation to address significant adverse impacts associated with proposed closure activities and to address facilities, equipment, or other project related remnants that will remain at the site;~~

2. ~~identify a schedule of activities for closure of the power plant site, transmission line corridor, and all other appurtenant facilities constructed as part of the project;~~

3. ~~identify any facilities or equipment intended to remain on site after closure, the reason, and any future use; and~~

4. ~~address conformance of the plan with all applicable laws, ordinances, regulations, standards, and local/regional plans in existence at the time of facility closure, and applicable conditions of certification.~~

~~Prior to submittal of the proposed facility closure plan, a meeting shall be held between the project owner and the Energy Commission CPM for the purpose of discussing the specific contents of the plan.~~

~~In the event that there are significant issues associated with the proposed facility closure plan's approval, or if the desires of local officials or interested parties are inconsistent with the plan, the CPM shall hold one or more workshops and/or the Energy Commission may hold public hearings as part of its approval procedure.~~

~~As necessary, prior to or during the closure plan process, the project owner shall take appropriate steps to eliminate any immediate threats to public health and safety and the environment, but shall not commence any other closure activities until the Energy Commission approves the facility closure plan.~~

~~UNPLANNED TEMPORARY CLOSURE/ON-SITE CONTINGENCY PLAN (COMPLIANCE-11)~~

~~In order to ensure that public health and safety and the environment are protected in the event of an unplanned temporary facility closure, it is essential to have an on-site contingency plan in place. The on-site contingency plan will help to ensure that all necessary steps to mitigate public health and safety impacts and environmental impacts are taken in a timely manner.~~

~~The project owner shall submit an on-site contingency plan for CPM review and approval. The plan shall be submitted no less than 60 days (or other time agreed to by the CPM) prior to commencement of commercial operation. The approved plan must be in place prior to commercial operation of the facility and shall be kept at the site at all times.~~

~~The project owner, in consultation with the CPM, will update the on-site contingency plan as necessary. The CPM may require revisions to the on-site contingency plan over the life of the project. In the annual compliance reports submitted to the Energy Commission, the project owner will review the on-site contingency plan, and recommend changes to bring the plan up to date. Any changes to the plan must be approved by the CPM.~~

~~The on-site contingency plan shall provide for taking immediate steps to secure the facility from trespassing or encroachment. In addition, for closures of more than 90 days, unless other arrangements are agreed to by the CPM, the plan shall provide for removal of hazardous materials and hazardous wastes, draining of all chemicals from storage tanks and other equipment, and the safe shutdown of all equipment. (Also see specific Conditions Of Certification for the technical areas of **Hazardous Materials Management** and **Waste Management.**)~~

~~In addition, consistent with requirements under unplanned permanent closure addressed below, the nature and extent of insurance coverage, and major equipment warranties must also be included in the on-site contingency plan. In addition, the status of the insurance coverage and major equipment warranties must be updated in the annual compliance reports.~~

~~In the event of an unplanned temporary closure, the project owner shall notify the CPM, as well as other responsible agencies, by telephone, fax, or e-mail, within 24 hours and shall take all necessary steps to implement the on-site contingency plan. The project owner shall keep the CPM informed of the circumstances and expected duration of the closure.~~

~~If the CPM determines that an unplanned temporary closure is likely to be permanent, or for a duration of more than 12 months, a closure plan consistent with the requirements for a planned closure shall be developed and submitted to the CPM within 90 days of the CPM's determination (or other period of time agreed to by the CPM).~~

~~UNPLANNED PERMANENT CLOSURE/ON-SITE CONTINGENCY PLAN (COMPLIANCE-12)~~

~~The on-site contingency plan required for unplanned temporary closure shall also cover unplanned permanent facility closure. All of the requirements specified for unplanned temporary closure shall also apply to unplanned permanent closure.~~

~~In addition, the on-site contingency plan shall address how the project owner will ensure that all required closure steps will be successfully undertaken in the event of abandonment.~~

~~In the event of an unplanned permanent closure, the project owner shall notify the CPM, as well as other responsible agencies, by telephone, fax, or e-mail within 24 hours and shall take all necessary steps to implement the on-site contingency plan. The project owner shall keep the CPM informed of the status of all closure activities.~~

~~A closure plan, consistent with the requirements for a planned closure, shall be developed and submitted to the CPM within 90 days of the permanent closure or another period of time agreed to by the CPM.~~

~~POST CERTIFICATION CHANGES TO THE ENERGY COMMISSION DECISION: AMENDMENTS, OWNERSHIP CHANGES, STAFF APPROVED PROJECT MODIFICATIONS AND VERIFICATION CHANGES (COMPLIANCE-13)~~

~~The project owner must petition the Energy Commission pursuant to Title 20, California Code of Regulations, section 1769, in order to modify the project (including linear facilities) design, operation or performance requirements, and to transfer ownership or operational control of the facility.~~ **~~It is the responsibility of the project owner to contact the CPM to determine if a proposed project change should be considered a project modification pursuant to section 1769.~~** ~~Implementation of a project modification without first securing Energy Commission, or Energy Commission staff approval, may result in enforcement action that could result in civil penalties in accordance with section 25534 of the Public Resources Code.~~

~~A petition is required for **amendments** and for **Staff approved project modifications** as specified below. Both shall be filed as a "Petition to Amend." Staff will determine if the change is significant or insignificant. For verification changes, a letter from the project owner is sufficient. In all cases, the petition or letter requesting a change should be submitted to the CPM, who will file it with the Energy Commission's Dockets Unit in accordance with Title 20, California Code of Regulations, section 1209.~~

~~The criteria that determine which type of approval and the process that applies are explained below. They reflect the provisions of Section 1769 at the time this condition was drafted. If the Commission's rules regarding amendments are amended, the rules in effect at the time an amendment is requested shall apply.~~

CONDITION NUMBER	SUBJECT	DESCRIPTION
COM-1	Unrestricted Access	The project owner shall grant Energy Commission staff and delegate agencies or consultants unrestricted access to the power plant site.
COM-2	Compliance Record	The project owner shall maintain project files on-site. Energy Commission staff and delegate agencies shall be given unrestricted access to the files.
COM-3	Compliance Verification Submittals	The project owner is responsible for the delivery and content of all verification submittals to the CPM, whether conditions were satisfied by work performed by the project owner or his agent.
COM-4	Pre-construction Matrix and Tasks Prior to Start of Construction	Construction shall not commence until all of the following activities/submittals have been completed: • Project owner has submitted a pre-construction matrix identifying conditions to be fulfilled before the start of construction; • Project owner has completed all pre-construction conditions to the CPM's satisfaction; and • CPM has issued a letter to the project owner authorizing construction.
COM-5	Compliance Matrix	The project owner shall submit a compliance matrix (in a spreadsheet format) with each Monthly and Annual Compliance Report, which includes the current status of all **Compliance** Conditions of Certification.
COM-6	Monthly Compliance Reports and Key Events List	During construction, the project owner shall submit Monthly Compliance Reports (MCRs) which include specific information. The first MCR is due 1 month following the docketing of the Energy Commission's Decision on the project and shall include an initial list of dates for each of the events identified on the Key Events List.
COM-7	Annual Compliance Reports	After construction ends, and throughout the life of the project, the project owner shall submit Annual Compliance Reports (ACRs) instead of Monthly Compliance Reports.
COM-8	Confidential Information	Any information the project owner designates as confidential shall be submitted to the Energy Commission's Executive Director with a request for confidentiality.
COM-9	Annual Fees	Required payment of the Annual Energy Facility Compliance Fee.
COM-10	Amendments, Staff-Approved Project Modifications, Ownership Changes, and Verification Changes	The project owner shall petition the Energy Commission to delete or change a condition of certification, modify the project design or operational requirements, and/or transfer ownership or operational control of the facility. [next page]
COM-11	Reporting of Complaints, Notices, and Citations	Prior to the start of construction, the project owner shall provide all property owners within a 1-mile radius a telephone number to contact project representatives with questions, complaints, or concerns. The project owner shall respond to all recorded complaints within 24 hours. Within 10 days of receipt, the project owner shall report to the CPM all notices, complaints, violations, and citations.

COM-12	Site Contingency Plan	No less than 60 days prior to the start of commercial operation, the project owner shall submit an Emergency Response Site Contingency Plan to ensure protection of public health and safety and environmental quality during a response to an emergency.
COM-13	Incident-Reporting Requirements	The project owner shall notify the CPM within 1 hour of an incident and submit a detailed incident report within 30 days, maintain records of incident report, and submit public health and safety documents with employee training provisions.
COM-14	Non-Operation	No later than 2 weeks prior to a facility's planned non-operation, or no later than 2 weeks after the start of unplanned non-operation, the project owner shall notify the CPM, interested agencies and nearby property owners of this status. During non-operation, the project owner shall provide written updates to the CPM.
COM-15	Facility Closure Planning	Within 60 days after initiating commercial operation, the project owner shall submit a Provisional Closure Plan and Cost Estimate for permanent closure. At least 3 years prior to closing, the project owner shall submit a Final Closure Plan and Cost Estimate.

DECLARATION OF
James Adams

I**, James Adams,** declare as follows:

1. I am presently employed by the California Energy Commission in the Environmental Office of the Siting, Transmission and Environmental Protection Division as a Planner II.

2. A copy of my professional qualifications and experience is attached hereto and incorporated by reference herein.

3. I prepared the staff testimony on **Land Use** for the **Palen Solar Electric Generating System Final Staff Assessment,** based on my independent analysis of the Application for Certification and supplement hereto, data from reliable documents and sources, and my professional experience and knowledge.

4. It is my professional opinion that the prepared testimony is valid and accurate with respect to the issue addressed therein.

5. I am personally familiar with the facts and conclusions related in the testimony and if called as a witness could testify competently thereto.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge and belief.

Dated: August 5, 2013 Signed: James Adams

At: Sacramento, California

James S. Adams
Environmental Protection Office
California Energy Commission
1516 Ninth Street
Sacramento, CA 95814-5504
PH (916) 653-0702, FAX (916) 654-3882
Jim.Adams@energy.ca.gov

5/1999
Present **Environmental Planner**

Review applications for certification to acquire permits from the California Energy Commission to build electric generating power plants. Specific technical fields include socioeconomics and traffic and transportation.

11/1997
Present **Energy and Resource Consultant**

Provide clients with technical expertise on various issues related to natural resource use and development. Current activities include managing an Intervention by the Redwood Alliance before the California Public Utilities Commission regarding the decommissioning of the Humboldt Bay Power Plant's nuclear reactor.

9/1994--
10/1997 **Senior Analyst - Safe Energy Communication Council (SECC)**

Responsible for developing and/or implementing campaigns on various energy issues involving the promotion of energy efficiency and renewable energy and advocating less reliance on nuclear power. Managed educational outreach efforts to newspaper editorial writers throughout the U.S. to encourage coverage of energy issues. Participated in meetings and negotiations with key Clinton administration officials, members of Congress and staff, national coalitions, and grassroots organizations on important energy issues (e.g. U.S. Department of Energy Budget for Fiscal Years 1996-1998). Successfully raised $140,000 from private foundations to support SECC activities.

6/1978--
12/1992 **Principal Consultant - Redwood Alliance**

Provided consulting services to the Alliance; a renewable energy/political advocacy organization. Major responsibilities included managing and/or participating in several interventions/appearances before the California Public Utilities Commission, California Energy Commission, California Legislature, U.S. Congress and the U.S. Nuclear Regulatory Commission. Issues included electric utility planning options, greater reliance on energy efficiency and renewable energy, nuclear power economic analyses, decommissioning cost estimates, and nuclear waste management and disposal.

2/1983--
8/1986 **Natural Resource Specialist**
Assisted private consulting, firms, non-profit corporations and government agencies in various projects related to the enhancement and protection of national forests in Northern California and Southern Oregon. This included contracts with the U.S. Forest Service, Fish and Wildlife Service, National Park Service, the California Coastal Conservancy, and private landowners.

6/1978--
1999 Consultant/Journalist/Paralegal/Lobbyist
Throughout the period of work outlined above, I have written a considerable amount of news articles and reports connected to ongoing-projects and issues of personal interest. The leg, al/administrative interventions have required extensive paralegal work to support attorneys, and technical expertise to identify and assist consultants. In addition, many of the projects required consulting services and lobbying, at the local, state and federal level whenever necessary, as well as working with the print and television media as appropriate.

From 1978 through 1984 1 served on the Board of Directors for two locals non-profit agencies devoted to sustainable community development, Redwood Community Development Council and Redwood Community Action Agency (RCAA). I also was hired on staff at RCAA as a natural resource specialist which is explained more fully above. I am proficient with computers, printers, fax machines and related equipment.

EDUCATION

M.A. Social Science. Political science and natural resources emphasis. California State University at Humboldt. Graduated December 1988.

B.A. Political Science. Political and economic aspects of natural resource development, with a particular emphasis in forest ecology and appropriate technology. California State University at Humboldt. Graduated June 1978.

Academic
Honors. Member of PI GAMMU MU Honor Society since 1986.

MILITARY SERVICE

7/1969--
9/1975 U.S. Navy. Air Traffic Controller.
Honorable Discharge.

DECLARATION OF
Edward Brady

I, **Edward Brady,** declare as follows:

1. I am presently employed by the California Energy Commission in the Engineering Office of the Siting, Transmission and Environmental Protection Division as a Mechanical Engineer.

2. A copy of my professional qualifications and experience is attached hereto and incorporated by reference herein.

3. I prepared the staff testimony on **Power Plant Efficiency and Reliability** for the **Palen Solar Electric Generating System Final Staff Assessment,** based on my independent analysis of the Application for Certification and supplement hereto, data from reliable documents and sources, and my professional experience and knowledge.

4. It is my professional opinion that the prepared testimony is valid and accurate with respect to the issue addressed therein.

5. I am personally familiar with the facts and conclusions related in the testimony and if called as a witness could testify competently thereto.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge and belief.

Dated: 8/2/13 Signed: Edward Brady

At: Sacramento, California

Edward James Brady
Mechanical Engineer

Summary of Experience

Forty years of experience in the profession of mechanical engineering as a staff engineer to the California Energy Commission, engineering consultant, design group supervisor in a major power plant project, senior engineer for a gas and electric utility, sales and design engineer for a contractor, and instructor in a community college.

Education

- BSME, Santa Clara University, 1972
- Graduate Engineering Studies, Santa Clara University
- Graduate Business Studies, University of San Francisco
- Continuing Education, UC Extension

Professional Registration

- Mechanical Engineer (M17924) California
  (25505) Washington
  (33082) Colorado
  (9248, Inactive) Nevada

- Civil Engineer (C36194) California

Affiliations

- American Society of Mechanical Engineers (ASME), Member
- American Society of Heating, Refrigerating and Air Conditioning Engineers (ASHRAE), Member
- International Code Council (ICC), Member
- International Association of Plumbing and Mechanical Officials (IAPMO), Member
- National Fire Protection Association (NFPA), Member

Curriculum Vitae

2011 – Present	**Staff Mechanical Engineer**, California Energy Commission, Siting, Transmission, and Environmental Protection Division (STEP). Performs analysis of generating capacity, reliability, efficiency, noise and vibration, and the mechanical, civil, electrical, and structural aspects of power plant siting and construction cases.
1988-2011	**Principal Mechanical Engineer,** Brady Engineering. Provided design and consulting services for the permitting and construction of industrial and commercial facilities, and residential buildings in the fields of heating, ventilating air conditioning (HVAC), plumbing, fire protection and energy analyses.
1984-1988	**Design Group Supervisor,** Joint PG&E and Bechtel Project. Worked as the mechanical group supervisor responsible for the design modifications required for the licensing of Diablo Canyon Power Plant, Units 1 and 2.
1980-1988	**Senior Mechanical Engineer,** PG&E Civil Engineering Department, Architectural Section. Provided work group supervision and design of building mechanical systems for common utility plant facilities (CUP) and balance of plant systems for power production facilities.
1977-1980	**Mechanical Engineer,** PG&E Civil Engineering Department, Architectural Section. Provided HVAC and plumbing design for CUP and power production facilities.
1974-1977	**Instructor,** San Francisco Community College District, John O'Connell Evening School. Provided apprenticeship training in the technical fields of HVAC and refrigeration.
1977	**Design Engineer,** Charles and Braun Consulting Engineers, San Francisco. Worked as a staff designer in the fields of HVAC and plumbing for commercials facilities include a sentence detention facilities and a proto-type regional facility for a federal agency.
1972-1976	**Sales and Design Engineer,** Scatena York Company, San Francisco. Worked as a sales and design engineer for a refrigeration contractor, which provided design and installation of refrigeration systems for supermarkets and cold storage facilities.

Power Plant/Utility Experience

California Energy Commission, Rio Mesa Solar Electric Generation Station (RMSEGS). 500 MW Solar Power Tower. Riverside County

, Hidden Hills Solar Electric Generating Station (HHSEGS). 500 MW Solar Power Tower. Inyo County.

, Hydrogen Energy California (HECA). 405 MW Combined Cycle, Fuel Gasification, CO_2 Sequestration, Ammonia Production. Kern County

, Quail Brush Generating Project (QBGP). 1100 MW Reciprocating Engine Electric Generation. City of San Diego

, Huntington Beach Energy Project (HBEP). 939 MW Combined Cycle. City of Huntington Beach.

, Redondo Beach Energy Project (RBEP). 496 MW Combined Cycle. City of Redondo Beach, Los Angeles County.

PG&E , Diablo Canyon Power Plant, Units 1 and 2. Licensing of safety related systems.
, Diablo Canyon Power Plant, Administration Building, SLO County Emergency Response Building

, Geysers Power Plant, Units 16, 17, 20, and 21. Ventilation and cooling for turbine building and hazardous waste disposal facilities, administration building.

, Helms Pumped Storage Facility, Kern County. Smoke control ventilation for underground transformer vaults.

, Humboldt No. 3, Eureka. Decommissioning of nuclear facility and construction of hazardous materials storage and handling.

, Moss Landing Power Plants, Units 1 through 6, Monterey County

, Morro Bay Power Plant, Morro Bay

, Hunters Point Power Plant, San Francisco

, Potrero Power Plant, San Francisco. Combined Cycle

, Gas Transmission Facilities, Line 300 and 400, Topock and Corning Compressor Stations, McDonald Island and Brentwood Gas Storage Facilities

, Central Computer Facilities, San Francisco and Vacaville

, 77 Beale Street, San Francisco. Energy Management System

, 215 Market Street, San Francisco. Boiler Replacement

, Underground Fuel Tank Replacement. Upgrade of more than 500 gallon fuel storage tanks to meet double containment requirements.

, Contra Costa Power Plants, Unit 1 through 6, Water Treatment

, Pittsburg Power Plants, Unit 1-5, Water Treatment Facilities

, Avon, Martinez and Oleum (AVO), Water Treatment Upgrade

, Tiger Creek Powerhouse, North Fork Feather River

, Kirchoff No. 2 Pump Storage Facility.

, Technical Support Services, Marketing Department

South Bay Sanitary Authority, 1400 Radio Road, Redwood Shores. Gas piping and boiler conversion.

DECLARATION OF
Huei-An (Ann) Chu, Ph.D.

I, **Huei-An (Ann) Chu,** declare as follows:

1. I am presently employed by the California Energy Commission in the Engineering Office of the Siting, Transmission and Environmental Protection Division as a Air Resources Engineer.

2. A copy of my professional qualifications and experience is attached hereto and incorporated by reference herein.

3. I prepared the staff testimony on **Public Health** for the **Palen Solar Electric Generating System Final Staff Assessment,** based on my independent analysis of the Application for Certification and supplement hereto, data from reliable documents and sources, and my professional experience and knowledge.

4. It is my professional opinion that the prepared testimony is valid and accurate with respect to the issue addressed therein.

5. I am personally familiar with the facts and conclusions related in the testimony and if called as a witness could testify competently thereto.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge and belief.

EDUCATION

PhD, Environmental Sciences and Engineering, 05/2006
School of Public Health, University of North Carolina at Chapel Hill
Area of Specialization: Environmental Risk Assessment, Environmental Management and Policy, Risk-Based Regulation, Biostatistics, Environmental Epidemiology

MEM, Environmental Management, 05/2000
School of Forestry and Environmental Studies, Yale University, New Haven, CT

MS, Environmental Engineering, 06/1998
National Taiwan University, Taipei, Taiwan

BA, Geography, with honors, 06/1996
National Taiwan University, Taipei, Taiwan

SKILLS

Language: Fluent in Chinese and English.

Computer software and programming skills: HARP, SAS, Stata, Minitab, ArcGIS, ArcView, ArcInfo, Stella, Crystal Ball, ISC, ERMapper, Microsoft Excel, PowerPoint, Word.

WORK EXPERIENCE

Air Resources Engineer, California Energy Commission, 1/12/2012 - Present
- Independently performs responsible, varied analyses assessing air quality and public health impacts of energy resource use and large electric power generation projects in California.
- Model air quality and public health impacts of stationary sources using HARP (Hot Spot Analysis and Reporting Program).
- Identify air quality and public health impacts of stationary sources and measures to mitigate these impacts following California Environmental Quality Act and regulations of US EPA (including the National Environmental Policy Act), ARB, and the Districts.
- Collect, analyze, and evaluate data on the effects of air pollutants and power plant emissions on human health, and the environment.
- Ensure conditions of certification are met and recommending enforcement actions for violations.

Research Associate, Taiwan Development Institute, 10/01/2010 – 12/31/2011
- Provided professional consultation for the environmental risk assessment of Taiwan's techno-industrial development initiatives
- Reviewed the environmental risk assessment reports of Taiwan's techno-industrial development initiatives
- Presented in various distinguished lecturer series about environmental risk assessment

Consultant, Chu Consulting, 08/2007 - 07/2010
- Conducted a cumulative risk assessment to evaluate the risk associated with the emissions of VOCs from a petrochemical plants in southern Taiwan
- Used EPA's ISC3 model (based on Gaussian dispersion model) to simulate the dispersion and deposition of VOCs from this petrochemical plant to the neighboring areas, then used ArcGIS to spatially combine the population data and VOC simulation data (and further calculated risks)

- Built a framework of risk-based decision making to set the emission levels of VOCs to reduce people's exposure and the risk of experiencing health problems
- Presented in conference: SRA 2007
- Awarded: CSU-Chico BBS Faculty Travel Funds (2007)

Environmental Justice Intern, Clean Water for North Carolina (CWFNC), Summer, 2005
- Reviewed and critiqued key state environmental policies and the federal EPA Public Participation Policy.
- Interviewed impacted communities, member organizations of the NC Environmental Justice Network, state policy officials about how those policies are actually implemented.
- Wrote a report about the survey and review of environmental justice needs for key state policies.
- Report Publication: "Achieving Environmental Justice in North Carolina Public Participation Policy" (Aug, 2005).

Volunteer, New Haven Recycles and Yale Recycling, 08/1998 – 05/2000
- Promoted recycling and conservation
- Checked trash cans (chosen randomly) and recycling bins at each entryway of residential college, then gave grades.

Volunteer, Urban Resource Initiative (URI), Summer, 1998
- Planted trees for local community of New Haven for a better and sustainable environment

RESEARCH EXPERIENCE

Postdoctoral Research

Department of Public Health Sciences, University of California, Davis, 07/01/2010 - present
Research advisor: Dr. Deborah H. Bennett and Dr. Irva Hertz-Picciotto
- Work on two projects: NIEHS-funded ***Childhood Autism Risks from Genetics and Environment (CHARGE)*** and EPA-funded ***Study of Use of Products and Exposure Related Behavior*** **(*SUPERB)***.
- Perform statistical and quantitative analyses with SAS to analyze collected house dust data and children's urine concentrations of metabolites.
- Conduct exposure assessment to investigate if pesticides, flame retardants, and phthalates are risk factors for children autism.
- Conduct exposure assessment to explore the relationships between children's exposure to phthalate, benzophenone-3 (oxybenzone), triclosan, and parabens, and the use of personal care products.
- Produce scholarly peer-reviewed publications of methodology and findings, and write the final reports of both projects.

Carolina Environmental Program, University of North Carolina at Chapel Hill, 01/01/2006 – 12/31/2006
Research advisor: Dr. Douglas J. Crawford-Brown
- Applied a framework of risk-based decision-making to perchlorate in drinking water. (Awarded: SRA Annual Meeting Travel Award 2006)
- Conducted a material and energy flow analysis (MEFA) to quantify the overall environmental impact of Bank of America operations, and quantitatively analyze the strategies BOA might adopt to reduce these impacts and achieve sustainability. (Report Publication: "Environmental Footprint Assessment")

Doctoral Research, 08/2000-12/2005

Department of Environmental Sciences and Engineering, School of Public Health, University of North Carolina at Chapel Hill
Research advisor: Dr. Douglas J. Crawford-Brown
- Dissertation topic: "**A framework of Risk-Based Decision Making by Characterizing Variability and Uncertainty Probabilistically: Using Arsenic in Drinking Water as an Example**".
- Conducted risk assessment for arsenic in drinking water.
- Conducted theoretical analysis on the variability and uncertainty issues of risk assessment.

- Conducted a meta-analysis to improve dose-response assessment.
- Conducted analytical and numerical analysis to build a new framework of risk-based decision-making which can be applied coherently across the regulation decisions for different contaminants.
- Presented in conferences: APPAM (2004), SRA (2004, 2005 and 2006), DESE Seminar (2005), CEP Symposium on Safe Drinking Water (2006).
- Awarded: SRA Annual Meeting Student Travel Award (2004 & 2005), UNC-CH Graduate School Travel Grants (2004), UCIS Doctoral Research Travel Awards (2002).

Master’s Research

School of Forestry and Environmental Studies, Yale University, 08/1999 - 06/2000
Research advisor: Dr. Xuhui Lee

- Master’s project: “**Forest Stand Dynamics and Carbon Cycle**”.
- Research project: “Monitoring Forest CO_2 Uptaking”
- Used remote sensing (ERMapper) to investigate the role of forest in the uptake of CO_2.
- Awarded from Teresa Heinz Scholars for Environmental Research Program (2000) and Klemme Award (1999).

Graduate Institute of Environmental Engineering, National Taiwan University, 06/1996 - 06/1998
Research advisor: Dr. Shang-Lien Loh

- Master’s thesis: “**The Loads of Air Pollutants from Urban Areas on a Neighboring Dam and its Water Quality**”
- Research Projects: “Research on Air Pollutant Deposition in Urban Areas” and “the Fate and Flow of Recyclable Materials”
- Used Gaussian’s Dispersion model (ISC3) to investigate the loads of air pollutants on dam water.

TEACHING EXPERIENCE

Lecturer

Department of Environmental Studies, California State University at Sacramento

- Environmental Politics and Policy, Fall 2011

Department of Geological & Environmental Science, California State University at Chico

- Environmental Risk Assessment, Spring 2009 & 2010
- Applied Ecology, Spring 2008
- Pollution Ecology, Fall, 2007

Department of Geography & Planning, California State University at Chico

- Seminar in Applied Geography & Planning – Environmental Regulation and Policy, Fall, 2007

Department of Forestry and Environmental Resources, North Carolina State University

- Environmental Regulation, Fall, 2006

Teaching Assistant

Department of Environmental Sciences and Engineering, UNC-Chapel Hill

- Environmental Risk Assessment, Spring, 2002
- Introduction to Environmental Science, Fall, 2001
- Analysis and Solution of Environmental Problems, Fall, 2001

Lab Instructor

Department of Environmental Sciences and Engineering, UNC-Chapel Hill

- Biology for Environmental Science, Fall, 2000

Graduate Institute of Environmental Engineering, National Taiwan University

- Water Quality Analysis, Fall, 1997

AWARDS and HONORS

- CSU-Chico BBS Faculty Travel Funds, 2007
- Member of Society of Risk Analysis (SRA), 2006-2008
- SRA Annual Meeting Student Travel Award, 2004-2006
- UNC-CH Graduate School Travel Grants, 2004
- Member of Association for Public Policy Analysis and Management (APPAM), 2004-2005
- UCIS Doctoral Research Travel Awards, 2002
- Graduate Student Teaching and Research Assistantships, 2000-2005
- Teresa Heinz Scholars for Environmental Research Program, 2000
- Yale Forestry & Environmental Studies, Klemme Award, 1999

DECLARATION OF
Ann Crisp

I, **Ann Crisp,** declare as follows:

1. I am presently employed by the California Energy Commission in the Environmental Office of the Siting, Transmission and Environmental Protection Division as a Staff Biologist.

2. A copy of my professional qualifications and experience is attached hereto and incorporated by reference herein.

3. I helped prepare the staff testimony on **Biological Resources** for the **Palen Solar Electric Generating System Final Staff Assessment,** based on my independent analysis of the Application for Certification and supplement hereto, data from reliable documents and sources, and my professional experience and knowledge.

4. It is my professional opinion that the prepared testimony is valid and accurate with respect to the issue addressed therein.

5. I am personally familiar with the facts and conclusions related in the testimony and if called as a witness could testify competently thereto.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge and belief.

Dated: 8/2/2013 Signed: Ann Crisp

At: Sacramento, California

Ann M. Crisp

Employment History

California Energy Commission

Planner II – Staff Biologist *03/2010 to present*

As a staff biologist with the Energy Commission, Ms. Crisp analyzes the biological resource components of energy facilities siting applications to assess resource impacts, develop mitigation, and to evaluate compliance with applicable local, state, and federal laws, ordinances, regulations, and standards. This requires working closely with biological resource protection and management agencies, subject matter experts, and Energy Commission consultants as well as with other Energy Commission staff to ensure the best available information is included in staff analyses.

Robertson-Bryan, Inc.

Staff Biologist *11/2006 to 03/2010*

Ms. Crisp's duties with Robertson-Bryan, Inc. included development of technical study reports and presentations based on the conclusions of field studies for the Middle Fork American River Project (MFP) Integrated Licensing Process for the Placer County Water Agency. She conducted field studies in preparation of the biological resources component of the MFP and the Big Creek System Alternative Licensing Process for Southern California Edison Company (SCE) including wildlife reconnaissance surveys, protocol-level wildlife surveys (including bald eagle wintering and nesting surveys and California red-legged frog surveys) and botanical surveys (including special-status plant species, noxious weeds, and plants of cultural concern for Native Americans). Ms. Crisp prepared documents supporting various management plans as part of the Big Creek No. 4 Traditional Licensing Process for SCE, including yearly monitoring reports for the Sediment Management Plan, Noxious Weed Management Plan, and Valley Elderberry Longhorn Beetle Management Plan. She also prepared and reviewed technical reports and California Environmental Quality Act (CEQA)/National Environmental Policy Act (NEPA) chapters on terrestrial resources.

Pacific States Marine Fisheries Commission/ California Department of Fish and Game

Research Technician *03/2006 to 11/2006*

While working with the California Department of Fish and Game through a partnership with the Pacific States Marine Fisheries Commission, Ms. Crisp conducted various focused wildlife surveys including reptile and amphibian cover board surveys, small mammal mark-recapture surveys, burrowing owl nest surveys, and California tiger salamander larval surveys. She collaborated on design and execution vegetation sampling protocol at multiple survey areas.

California Department of Fish and Game

Scientific Aid *11/2005 to 01/2006*

Ms. Crisp led tours of the Nimbus Fish Hatchery to provide information on the function of the hatchery and fish biology to school groups and the general public.

Humboldt State Foundation / California Department of Fish and Game

Wildlife Research Assistant *03/2005 to 10/2005*

While working with the California Department of Fish and Game (CDFG) through a partnership with the Humboldt State Foundation, Ms. Crisp conducted field-based vegetation sampling to classify vegetation types/wildlife habitats on multiple CDFG Wildlife Areas and Ecological Reserves. She was responsible for data management and preparation for inclusion in a statewide database. Ms. Crisp also conducted focused wildlife surveys including reptile and amphibian cover board surveys, small mammal live-trapping surveys, and nocturnal mammal spotlight surveys.

Oregon State University

Research Technician *06/2004 to 09/2004*

Ms. Crisp conducted bat surveys and vegetation inventories and assessments on a bat survey crew in western Oregon. This included collecting data on bat activity using Anabat II detectors, capturing bats using mist nets and H-nets and collecting biological samples and morphological data and vegetation sampling.

Sacramento Regional County Sanitation District – Bufferlands

Senior Student Intern *07/2003 to 03/2004*

Ms. Crisp assisted with various habitat restoration and management projects within the 2,650-acres surrounding the Sacramento Regional Wastewater Treatment Plant. She conducted waterfowl and shorebird surveys as well as sensitive species surveys. Other duties included landscape maintenance and water quality monitoring.

DECLARATION OF
Christopher Dennis

I, **Christopher Dennis,** declare as follows:

1. I am presently employed by the California Energy Commission in the Engineering Office of the Siting, Transmission and Environmental Protection Division as an Engineering Geologist.

2. A copy of my professional qualifications and experience is attached hereto and incorporated by reference herein.

3. I prepared the staff testimony on **Waste Management** for the **Palen Solar Electric Generating System Final Staff Assessment,** based on my independent analysis of the Application for Certification and supplement hereto, data from reliable documents and sources, and my professional experience and knowledge.

4. It is my professional opinion that the prepared testimony is valid and accurate with respect to the issue addressed therein.

5. I am personally familiar with the facts and conclusions related in the testimony and if called as a witness could testify competently thereto.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge and belief.

Dated: August 1, 2013 Signed: C.B.M

At: Sacramento, California

CHRISTOPHER DENNIS, PG, CHG

EXPERIENCE SUMMARY

Mr. Dennis is a licensed Professional Geologist and Certified Hydrogeologist with the State of California, and a California Qualified Stormwater Practioner/Developer. Mr. Dennis has over 20 years of professional technical and management experience. Fourteen of those years, he worked in private industry as a consultant. For the last six years, he has worked in the Energy Commissions Siting, Transmission and Environmental Protection Division. Mr. Dennis has been a portfolio manager for several major oil companies and the East Bay Municipal Utility District. He actively managed Unocal CERT, ExxonMobil, and ChevronTexaco pipeline, service station, bulk fueling, and terminal sites.

EDUCATION/REGISTRATION/CERTIFICATIONS

Pepperdine Law School, Certificate in Dispute Resolution, 1997
Whittier College of Law, J.D., 1996
California State University, Fullerton, B.S. Geology, 1989
Certified Hydrogeologist, State of California #963
Professional Geologist, State of California #7184
Qualified Stormwater Practioner/Developer #767
OSHA-SARA 40-Hour Hazardous Waste Activity Training 29 CFR 1910.120

PROFESSIONAL HISTORY

2007 to Current California Energy Commission, Engineering Geologist
2004 to 2007 Science Applications International Corporation, Senior Geologist
2004 to 2004 Bay Consulting Services, LLC, Principal
2001 to 2004 Cambria Environmental Technology, Inc., Office Manager, Senior Geologist
2000 to 2001 Alisto Engineering, Inc, Senior Geologist
1998 to 2000 Alton Geoscience-TRC, Inc., Senior Geologist
1993 to 1995 GeoResearch, Inc., Project Manager
1990 to 1993 AeroVironment, Inc., Staff Geologist
1989 to 1990 Applied Geosciences, Inc., Technician

2007 to Current, California Energy Commission, Sacramento, CA
Engineering Geologist
Siting, Transmission, and Environmental Protection Division

One of the primary functions of the Energy Commission is CEQA review of license applications to build and operate power plants 50 MW and greater in California. In the Energy Commission's Engineering Office, Mr. Dennis helps fulfill this function by working through and managing a wide variety of CEQA and environmental policy issues. The product of this effort is expressed in expert testimony and staff analysis for siting new power plants and power plant compliance activity. His testimony and analyses cover soil and water resource management, waste management, geological hazards, and paleontological resource management. He participates as a technical speaker at public workshops as needed.

He has worked on simple-cycle, combined cycle, cogeneration, geothermal, and large-scale thermal solar power plants, and is familiar with most of the major power plants in construction and operation in California today. He has conducted construction and operation compliance inspections at many of these plants. Mr. Dennis also works on the Energy Commission's water policy, having help bring it to the foreground with his final staff assessment for the Abengoa Solar project license. When issues involving Energy Commission or state policy, Mr. Dennis participates in meetings with his deputy director where he provides input on his assessments and recommendations.

A list of power plant siting cases for which he has authored assessments, in whole or in part follows: Abengoa Solar (Solar Thermal), Chevron USA (Natural Gas), CPV Sentinel (Natural Gas), Imperial Solar

(Solar Thermal), Ivanpah SEGS (Solar Thermal), Palmdale Hybrid (Natural Gas-Solar Thermal), Quail Brush (Natural Gas), Rio Mesa SEGF (Solar Thermal), and San Joaquin Solar (Solar Thermal-Biomass). Mr. Dennis also works on power plant construction and operation compliance, some of which are: Abengoa Solar, Colusa, CPV Sentinel, Elk Hills, geothermal power plants, Henrietta, Inland Empire, Ivanpah SEGS, La Paloma, Marsh Landing, MountainView, TID Almond, SEGS III-VII, SEGS VII & IX, and Sutter.

Mr. Dennis has developed a broad knowledge of CEQA/NEPA impact analysis and mitigation involving water resources, water quality, soil resources, erosion hazards, geologic resources and hazards, paleontological resources, and waste management. The assessments he has authored involve basin-wide water management, basin overdraft, water quality, water conservation, recycled water, water transfers, groundwater recharge, flood potential, and wind/water soil erosion. He has worked on groundwater basin modeling, basin water balance estimates, and evaluations of groundwater drawdown impacts to groundwater quality, biology, and other groundwater users. He has also evaluated potential impacts from geologic hazards related to faults, earthquake related ground shaking, landslides, subsidence, compressive and expansive soils, and flood potential.

Mr. Dennis manages the Energy Commission’s Quarterly Fuel and Energy Reporting (QFER) program for the water use and wastewater generation of all power plants 20 MW and greater in California. He designed the forms used to collected the QFER water and wastewater data and developed a database to manage the data collected, and through the course of this data collection effort, developed constructive working relationships with plant operators. The QFER water and wastewater information collected is used by news agencies, federal and state agencies, and members of the public.

Mr. Dennis trains and manages students to assist him with the QFER data collection and power plant construction and operation compliance oversight. He has been frequently asked to act as the Unit Supervisor when the supervisor is away on vacation, and works with other Energy Commission employees and government agencies to focus on tasks and resolve issues.

2004 to 2007, Science Applications International Corporation, Sacramento, CA
Senior Geologist/Project Manager
Consultant for Chevron, Northern California

Mr. Dennis managed environmental compliance for several former crude oil and Bunker C pipeline right-of-way and pump stations sites within the Central California region. He consolidated all groundwater monitoring and sampling for the portfolio into one program and managed that program. He developed and implemented new written field QA/QC procedures for the entire portfolio of sites, and developed and implemented an analytical laboratory evaluation plan. He also initiated low-flow groundwater sampling from wells and the use of pre-packed filter screens in open boreholes to reduce water turbidity in samples collected, allowing laboratory detection limits to be low enough for polynuclear aromatic hydrocarbon impacted groundwater risk-assessment evaluation. He initiated a crude oil remediation study for the portfolio. Mr. Dennis also developed workplans and conducted subsurface soil and groundwater investigations and prepared reports documenting the results of those investigations. He developed a soil vapor survey workplan and installed multiple completion soil vapor wells. He also worked with a GIS team to incorporate all pertinent site data into a web-based GIS and geo-reference the GIS as appropriate. This portfolio required a significant amount of front-end planning and coordination. Mr. Dennis developed and managed all site budgets and billing, and performed annual staff reviews. As a senior project manager, Mr. Dennis was the geologist in responsible-charge for the work performed by other geologist in the office and while conducting work in the field.

2004 to 2004, Bay Consulting Services, LLC, Rocklin, CA
Consultant/Principal Owner

Mr. Dennis developed the company from a concept to a viable business. Provided environmental consulting services for Chevron Corp. projects and other environmental companies. Completed several closure requests with Tier I/II risk analysis. Conducted company billing and accounting.

2001 to 2004, Cambria Environmental Technology, San Ramon and Rocklin, CA
Senior Geologist/Office Manager
Consultant for Chevron and East Bay Municipal Utility District

Mr. Dennis started Cambria's Rocklin office and grew that office to a staff of over 12 in less than a year through initiative and hard work. He worked as a liaison for the client and regulators, developed and managed all site budgets and billing, and performed annual staff reviews, hiring, and employment termination.

Chevron, Northern California. Mr. Dennis managed environmental compliance for a portfolio of 40 to 60 Chevron Corp. service stations and bulk fuel plants in Northern California. He developed workplans and conducted subsurface soil and groundwater investigations for these sites, some of which were located in the sensitive Lake Tahoe area. Each site was unique with its own operational history and hydrogeologic conditions. He achieved regulatory closure of over 30 Chevron sites by application of active remediation and by demonstration that attenuation processes would naturally cleanup the refined fuel products in the soil and groundwater.

To bring these sites to regulatory closure, Mr. Dennis initially prepared workplans to develop an understanding of the site history, hydrogeologic conditions, and to identify the extent, concentration, and type of fuel product in the subsurface associated with the site. The workplans included regulatory record searches, aerial photographs evaluations, the design of soil borings and groundwater monitoring well networks for subsurface geology and aquifer characterization. Mr. Dennis then conducted site investigations pursuant to these regulatory approved workplans.

The site investigations included the drilling soil borings, logging of soil borings, and the collection of soil samples from the vadose zone, capillary fringe, and saturated zones for chemical and physical analyses and grab-groundwater samples for chemical analyses. Based on these results and field judgment, Mr. Dennis was responsible for the completion of soil vapor extraction wells and groundwater monitoring wells in accordance with industry guidelines and best professional practice. He also was the geologist in responsible-charge for the preparation of reports that evaluated the data collected and made conclusions and recommendations based on the results of the evaluation. As a senior project manager, Mr. Dennis was the geologist in responsible-charge for the work performed by other geologist in the office and while conducting work in the field.

Mr. Dennis helped develop and received State Underground Storage Tank (UST) Fund pre-approved for approximately 100 low-risk ChevronTexaco sites as part of a management transfer initiative. He also worked with Caltrans on a freeway (CA I-80) expansion project that required excavation and dewatering beneath a former Chevron site. Mr. Dennis worked with Caltrans to build into the Caltrans request for bid specifications for handling petroleum impacted excavated soils and water. As a result of this effort, the expansion project is now complete and the former Chevron site remediated.

East Bay Municipal Utility District, Northern California. Mr. Dennis brought to Cambria a three-year, $275K/yr maximum EBMUD contract. The contract focused on pre-trenching activity soil sampling/analysis for potential contaminant identification and soil disposal. He developed a small group of professionals to manage this portfolio. As part of this project, Mr. Dennis managed several EPA SW-846 statistical soil analysis projects at District landfill sites with volumes up to approximately 180,000 cubic yards of landfilled soil. He created and surveyed statistical grids on the landfills and characterized the soil for removal to Class III or Class II landfills. He also conducted site investigations and quarterly groundwater monitoring projects at EBMUD facilities at the Camanche and Pardee Reservoirs.
2000 to 2001, Alisto Engineering, Lafayette, CA
Senior Geologist/Project Manager
Consultant for Caltrans and Industrial Facilities

Caltrans, Northern California. Mr. Dennis conducted site investigations at Caltrans sites and conducted statistical analyses of the soil from the shoulders of several Caltrans highways in Southern California. He performed the statistical analyses to determine hazard levels of lead in the soil, which would assist in soil management planning in proposed highway construction corridors. The statistical analyses were performed on sample populations ranging from approximately 80 to 300.

Industrial Facilities, Northern California. Mr. Dennis also conducted site investigations at several industrial sites in Northern California. He developed storm water pollution prevention plans (SWPPPs) for development projects in downtown San Jose and a Caltrans project along CA I-680. Mr. Dennis worked as a liaison for clients and regulators, and developed and managed all site budgets and billing for both the industrial facilities and Caltrans projects.

1998 to 2000, Alton Geoscience-TRC, Concord, CA
Senior Geologist/Project Manager
Consultant for ExxonMobil and Quick Stop Markets

ExxonMobil and Quick Stop Markets, Northern California. Mr. Dennis managed environmental compliance for a portfolio of ExxonMobil and Quick Stop Markets service station and bulk fuel plant sites. He developed workplans and conducted subsurface soil and groundwater investigations. Mr. Dennis achieved regulatory closure of over 30 of these sites by application of active remediation and demonstration that attenuation processes would naturally cleanup the refined fuel products in the soil and groundwater. Site investigations included the drilling and logging of soil borings, and collection of soil samples from the vadose, capillary fringe, and saturated zones for chemical and physical analyses and grab-groundwater samples were collected for chemical analyses. Based on these results and field judgment, Mr. Dennis was responsible for the completion of soil vapor extraction wells and groundwater monitoring wells in accordance with industry guidelines and best professional practice. He was also responsible for the preparation of reports that evaluated the data collected and made conclusions and recommendations based on the results of the evaluation. Mr. Dennis also managed the application of high vacuum, dual-phase (soil vapor and groundwater) extraction at several of these sites.

Notably, after two years of negotiations, technical presentations, and meetings, Mr. Dennis secured the recession of a RWQCB cleanup and abatement order and site closure for a former bulk plant on the sensitive Napa River. This bulk fuel plant was one of several along the river and where the tidal influences on the river affected the petroleum product in the groundwater. Plumes of liquid and dissolved phase hydrocarbons were present in the groundwater at adjacent sites and at the subject site.

1993 to 1995, Project Manager, GeoResearch, Long Beach, CA
Staff Geologist/Project Manager
Consultant for Unocal CERT

Unocal CERT, Southern California. Mr. Dennis managed environmental compliance for a portfolio of Unocal CERT projects in Southern California. He developed workplans and conducted subsurface soil and groundwater investigations for these sites. He frequently utilized mobile laboratories to assist in the placement of soil borings, vapor extraction, and groundwater wells. He conducted risk assessments, site assessments, tanks pulls, station demolitions, aquifer and vapor extraction tests, and remediation system designs and installations.

1990 to 1993 Staff Geologist, AeroVironment, Monrovia, CA
Staff Geologist/Project Manager
Consultant for Industrial Sites and Air Force Base Projects

Industrial Sites and Air Force Base Projects, Southern California. Mr. Dennis managed industrial projects and participated on government projects as a project geologist. He was a team leader during field documentation over 400 former homestead sites at Edwards AFB using GPS technology. This documentation included well locations, archaeological finds, and biological concerns. Mr. Dennis helped develop a database to manage all the data collected. He also conducted groundwater sampling according to AFCEE protocols and conducted soil-vapor and geophysical surveys at Vandenberg AFB. He was a member of the design team of a mobile soil-vapor laboratory that housed a gas chromatograph for sample analysis, and was lead designer of an insitu soil-vapor sample collection system. Mr. Dennis also managed two field teams for monitoring landfill vapor emissions and subsurface migration at active San Bernardino and Riverside County operated landfills, wrote the standard operating procedures for the fieldwork, conducted field training, and prepared quarterly AQMD reports. He also developed the contract for and managed quarterly groundwater monitoring and sampling at the Powerine Oil Refinery in Santa Fe Springs.

DECLARATION OF
DAVID FLORES

I, **David Flores** declare as follows:

1. I am presently employed by the California Energy Commission in the Siting, Transmission and Environmental Protection Division as a **Planner 3-Supervisor.**

2. A copy of my professional qualifications and experience is attached hereto and incorporated by reference herein.

3. I reviewed and approved staff's testimony on **Traffic and Transportation** for the Palen Solar Electric Generating System based on my staff's independent analysis of the Application for Certification and supplements thereto, data from reliable documents and sources, and their professional experience and knowledge.

4. It is my professional opinion that the prepared testimony is valid and accurate with respect to the issue addressed therein.

5. I am personally familiar with the facts and conclusions related in the testimony and if called as a witness could testify competently thereto.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge and belief.

Dated: September 5, 2013 Signed: ______________________

At: Sacramento, California

DAVID FLORES

WORK EXPERIENCE

November 2009 to Present **Planner 3-Supervisor.** California Energy Commission, Energy Facilities Siting and Protection Division.

Perform a variety of supervisory, administrative, and analytical tasks. As supervisor, I am responsible for a staff of technical specialists and consultants performing analysis in the areas of natural gas power plant and solar thermal siting, electrical transmission line corridor planning, electrical transmission line corridor planning and energy policy/planning.I also provide staff support at public workshops and as a liaison to citizen committees.

September. 1998 to November 2009

Planner 2. California Energy Commission, Energy Facilities Siting and Protection Division.

Provide written technical analysis of proposed energy planning, conservation, transmission design, and development programs on land use, visual and traffic and transportation resources. Specific tasks include: the analysis of potential impacts; identification of suitable mitigation measures; preparation of testimony; participate in public workshops; present sworn testimony during evidentiary hearings, and propose monitoring to ensure compliance with local, state and federal environmental laws and regulations.

March 29,1988 to September 12, 1998

Senior Planner. County of Yolo Planning and Public Works Department

Senior Planner - Current and Advanced Planning (Resources Management and Planning)

Responsibilities included the following:

Administered the establishment of Planning schedules and timeframe completion schedules to four, associate planners; Administration and staff support to Planning Commission and Board of Supervisors; Staff support and liaison to citizen's committees. Preparation of Environmental documents (Negative Declarations, preparation of Environmental Impact Reports and Categorical Exemptions) in accordance with State and Federal Regulations.

June 1, 1976
to March 25, 1988 **Manager of Resources** Citizens Utilities Company of California

Responsibilities included the following:

Coordinated, planned and developed semi-annual and annual construction and operating and maintenance budgets for all Northern California operations. Assisted in the development of rate and fee schedules before the California Public Utilities Commission for all Northern California Operations. Directed five employees and twenty-five employees in the outlying California operations. Extensive experience in specification writing, project planning and scheduling, construction management, site supervision and effective customer relations for outlying areas.

EDUCATION

California State University @ Sacramento
University of California @Davis
Major: Environmental Studies
Minor: Business Administration

DECLARATION OF
Alvin Greenberg, Ph.D.

I, **Alvin Greenberg, Ph.D.** declare as follows:

1. I am presently a consultant to the California Energy Commission, Siting, Transmission, and Environmental Protection Division.

2. A copy of my professional qualifications and experience is attached hereto and incorporated by reference herein.

3. I helped prepared the staff testimony on **Hazardous Materials Management, Biological Risk Assessment of Avian Exposure to Concentrated Solar Radiation, Assessment of Impacts of Glint and Glare on Vehicles Traveling on I-10, and Worker Safety/Fire Protection** for the modified **Palen Solar Electric Generating System** (09-AFC-7C), based on my independent analysis of the Petition for Amendment dated December 17, 2012 and supplements hereto, responses to staff data requests, data from reliable documents and sources, and my professional experience and knowledge.

4. It is my professional opinion that the prepared testimony is valid and accurate with respect to the issue addressed therein.

5. I am personally familiar with the facts and conclusions related in the testimony and if called as a witness could testify competently thereto.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge and belief.

Name & Title: **Alvin J. Greenberg, Ph.D., QEP**
Principal Toxicologist

Dr. Greenberg has had over two decades of complete technical and administrative responsibility as a team leader in the preparation of human and ecological risk assessments, air quality assessments, hazardous materials handling and risk management/prevention, infrastructure vulnerability assessments, occupational safety and health, hazardous waste site characterization, interaction with regulatory agencies in obtaining permits, and conducting lead surveys and studies. He has particular expertise in the assessment of dioxins, lead, diesel exhaust, petroleum hydrocarbons, mercury, the intrusion of subsurface contaminants into indoor air, and the preparation and review of public health/public safety sections of EIRs/EISs. Dr. Greenberg's expertise in risk assessment has led to his appointment as a member of several state and federal advisory committees, including the California EPA Advisory Committee on Stochastic Risk Assessment Methods, the US EPA Workgroup on Cumulative Risk Assessment, the Cal/EPA Peer Review Committee of the Health Risks of Using Ethanol in Reformulated Gasoline, the California Air Resources Board Advisory Committee on Diesel Emissions, the Cal/EPA Department of Toxic Substances Control Program Review Committee, and the DTSC Integrated Site Mitigation Committee. Dr. Greenberg is the former Chair of the Bay Area Air Quality Management District Hearing Board, a former member of the State of California Occupational Health and Safety Standards Board (appointed by the Governor), and former Assistant Deputy Chief for Health, California OSHA. And, since the events of 9/11, Dr. Greenberg has been the lead person for developing vulnerability assessments, power plant security programs, and conducting safety and security audits of power plants for the California Energy Commission and has assisted the CEC in the assessment of safety and security issues for proposed LNG terminals. In addition to providing security expertise to the State of California, Dr. Greenberg was the Team Leader and main consultant to the State of Hawaii on the updating of their Energy Emergency Preparedness Plan.

Years Experience: 32

Education:

B.S. 1969 Chemistry, University of Illinois Urbana

Ph.D. 1976 Pharmaceutical/Medicinal Chemistry, University of California, San Francisco

Postdoctoral Fellowship 1976-1979 Pharmacology/Toxicology, University of California, San Francisco

Postgraduate Training 1980 Inhalation Toxicology, Lovelace Inhalation Toxicology Research Institute, Albuquerque, NM

Professional Registrations:

Board Certified as a Qualified Environmental Professional (QEP)
California Registered Environmental Assessor - I (REA) (program discontinued in 2012)
Fellow of the American Institute of Chemists (FAIC)

Professional Affiliations:

Society for Risk Analysis
American Chemical Society
National Fire Protection Association

Technical Boards and Committee Memberships - Present:

Squaw Valley Technical Review Committee
(appointed 1986)

Technical Boards and Committee Memberships - Past:

July 1996 – March 2002
Member, Bay Area Air Quality Management District Hearing Board
(Chairman 1999-2002)
September 2000 – February 2001
Member, State Water Resources Control Board Noncompliant Underground Tanks Advisory Group
January 1999 – June 2001
Member, California Air Resources Board Advisory Committee on Diesel Emissions
January 1994 - September 1999
Vice-Chairman, State Water Resources Control Board Bay Protection and Toxic Cleanup Program Advisory Committee
September 1998
Member, US EPA Workgroup on Cumulative Risk Assessment
April 1997 - September 1997
Member, Cal/EPA Private Site Manager Advisory Committee
January 1986 - July 1996
Member, Bay Area Air Quality Management District Advisory Council
(Chairman 1995-96)
January 1988 - June 1995
Member: California Department of Toxic Substance Control Site Mitigation Program Advisory Group
January 1989 - February 1995
Member: Department of Toxics Substances Control Review Committee, Cal-EPA

October 1991 - February 1992
Chair: Pollution Prevention and Waste Management Planning Task Force of the Department of Toxics Substances Control Review Committee, Cal-EPA

September 1990 - February 1991

Member: California Integrated Waste Management Board Sludge Advisory Committee

September 1987 - September 1988

ABAG Advisory Committee on Regional Hazardous Waste Management Plan

March 1987 - September 1987

California Department of Health Services Advisory Committee on County and Regional Hazardous Waste Management Plans

January 1984 - October 1987

Member, San Francisco Hazardous Materials Advisory Committee

March 1984 - March 1987

Member, Lawrence Hall of Science Toxic Substances and Hazardous Materials Education Project Advisory Board

Jan. 1, 1986 - June 1, 1986

Member, Solid Waste Advisory Committee, Governor's Task Force on Hazardous Waste

Jan. 1, 1983 - June 30, 1985

Member, Contra Costa County Hazardous Waste Task Force

Sept. 1, 1982 - Feb. 1, 1983

Member, Scientific Panel to Address Public Health Concerns of Delta Water Supplies, California Department of Water Resources

<u>Present Position</u>

January 1983- present

Owner and principal with Risk Sciences Associates, a Marin County, California, environmental consulting company specializing in multi-media human health and ecological risk assessment, air pathway analyses, hazardous materials management-infrastructure security, environmental site assessments, review and evaluation of EIRs/EISs, preparation of public health and safety sections of EIRs/EISs, and litigation support for toxic substance exposure cases.

<u>Previous Positions</u>

Jan. 2, 1983 - June 12, 1984

Member, State of California Occupational Safety and Health Standards Board (Cal/OSHA), appointed by the Governor

Aug. 1, 1979 - Jan. 2, 1983
Assistant Deputy Chief for Health, California Occupational Safety and Health Administration

Feb. 1, 1979 - Aug. 1, 1979
Administrative Assistant to Chairperson of Finance Committee, Board of Supervisors, San Francisco

Jan. 1, 1976 - Feb. 1, 1979
Research Pharmacologist and Postdoctoral Fellow, Department of Pharmacology and Toxicology, School of Medicine, University of California, San Francisco

Jan. 1, 1975 - Dec. 31, 1975
Acting Assistant Professor, Department of Pharmaceutical Chemistry, University of California, San Francisco

Experience

General

Dr. Greenberg has been a consultant in Hazardous Materials Management and Security, Human and Ecological Risk Assessment, Occupational Health, Toxicology, Hazardous Waste Site Characterization, and Toxic Substances Control Policy for over 32 years. He has broad experience in the identification, evaluation and control of health and environmental hazards due to exposure to toxic substances. His experience includes Community Relations Support and Risk Communication through experience at high-profile sites and presentations at professional society meetings.

He has considerable experience in the review and evaluation of exposure via the air pathway - particularly to emissions from power plants, refineries, and diesel exhaust - and a thorough knowledge of the regulatory requirements through his experience at Cal/OSHA, the BAAQMD Hearing Board, as a consultant to the California Energy Commission, and in preparing such assessments for local government and industry. He has assessed exposures to diesel exhaust during construction and operations of stationary and mobile sources and has testified at evidentiary hearings numerous times on this subject.

He is presently assisting the California Energy Commission in assessing the risks to workers and the public of proposed power plants and hazardous wastes on those sites. His experience in hazard identification, exposure assessment, risk assessment, occupational safety and health, emergency response, and Critical Infrastructure Protection has made him a valuable part of the CEC team addressing this issue. He has conducted numerous evaluations of the safety and hazards of natural gas pipelines for the CEC and has presented his findings and recommendations at public meetings and evidentiary hearings.

He served for over five years as the Vice-chair of the California State Water Resources Control Board Advisory Committee convened to address toxic substances in sediments in bays, rivers, and estuaries. He has been a member of the Squaw Valley Technical Review Committee since 1986 establishing chemical application management plans at golf courses to protect surface and groundwater quality. He has also conducted numerous ecological risk assessments and characterizations, including those for marine and terrestrial habitats.

Dr. Greenberg has extensive experience in data collection and preparation of human and ecological risk assessments on numerous military bases and industrial sites with Cal/EPA DTSC and RWQCB oversight. He has also been retained to provide technical services to the Cal/EPA Department of Toxic Substances Control (preparation of human health risk assessments) and the Office of Environmental Health Hazard Assessment (review and evaluation of air toxics health risk assessments and preparation of profiles describing the acute and chronic toxicity of toxic air contaminants). He has also conducted several surveys of sites containing significant lead contamination from various sources including lead-based paint, evaluated potential occupational exposure to lead dust and fumes in industrial settings, prepared numerous human health risk assessments of lead exposure, and prepared safety and health plans for remedial investigation of lead contaminated soils. Dr. Greenberg is also a recognized expert on the requirements of California's Proposition 65 and has served as an expert on Prop. 65 litigation.

Sites with EPA, RWQCB and/or DTSC Oversight

Dr. Greenberg has specific experience in assessing human health and ecological risks at contaminated sites at the land/water interface, including petroleum contaminants, metals, mercury, and VOCs at several locations in California including Oxnard, Richmond, Avila Beach, Mare Island Naval Shipyard, San Diego, Hollister, San Francisco, Hayward, Richmond, the Port of San Francisco, and numerous other locations. He has used Cal/EPA methods, US EPA methods, and ASTM Risk Based Corrective Action (RBCA) and Cal/Tox methodologies. He is extremely knowledgeable about SWRCB and SF Bay RWQCB regulations on underground storage tank sites and with ecological issues presented by contaminated sediments including sediment analysis, toxicity testing, tissue analysis, and sediment quality objectives. Dr. Greenberg served on the State Water Resources Control Board Bay Protection and Toxic Cleanup Program Advisory Committee from 1994 until the end of the program in 1999.

Dr. Greenberg experience on many of these contaminated sites has been as a consultant to local governments, state agencies, and citizen groups. He assisted the City and County of San Francisco in developing local ordinance requiring soil testing (Article 20, Maher ordinance) and hazardous materials use reporting (Article 21, Walker ordinance). He served as the City of San Rafael's consultant to provide independent review and evaluation of the site characterization and remedial action plan prepared for a former coal gasification site. He was a consultant to a citizen group in northern California regarding exposure and risks due to accidental releases from a petroleum refinery and assisted in the assessment of risks due to crude petroleum contamination of a southern California beach. He has prepared a number of risk assessments addressing crude petroleum, diesel and gasoline contamination, including coordinating site investigations, environmental monitoring, and health risk assessment for the County of San Luis Obispo regarding Avila Beach subsurface petroleum contamination. That high-profile project lasted for over one year and Dr. Greenberg managed a team of experts with a budget of $750,000. Another high-profile project included the preparation of an extensive comprehensive human and ecological risk assessment for the Hawaii Office of Space Industry on rocket launch impacts and transportation/storage of rocket fuels at the southern end of the Big Island of Hawaii. Dr. Greenberg's risk assessments were part of the EIS for the project. Dr. Greenberg also worked on another high-profile project conducting Air Pathway Analysis of off-site and on-site impacts from landfill gas constituents, including indoor and outdoor air measurements, air dispersion modeling, flux chamber investigations, and health risk assessment for the County of Santa Barbara. Dr. Greenberg has conducted RI/FS work, prepared health risk assessments, evaluated hazardous waste sites and hazardous materials use at numerous locations in California, Hawaii, Oregon, Minnesota, Michigan, and New York. He has considerable experience in the development of clean-up standards and the development of quantitative risk assessments for site RI/FS work at CERCLA sites, as well as site closures, involving toxic substances and petroleum hydrocarbon wastes. He is experienced in working with both Region IX EPA and the State of California DTSC in negotiating clean-up standards based on the application of both site-specific and non site-specific health and ecological based clean-up criteria. He has significant experience in the development of site chemicals of concern list, quantitative data quality levels, site remedial design, the site closure process, the design and execution of data quality programs and verification of data quality prior to its use in the decision making process on large NPL sites.

Human Health Risk Assessments for the Ophir Road, 20th St., Durham, and Norcal Scrap Metal Recycling Sites (September 2010 – present)

Human Health Risk Assessment and Hazardous Material Assessment at the former Nestle Waters of North America, Inc. McCloud Site (August 2012)

Review and Evaluation of the Extent of Contamination and Risk Posed by the former Unocal Tank Farm Area, San Luis Obispo, CA (July 2009 – April 2011)

Review and Evaluation of the former Mill Hazardous Waste Site, North Fork, CA (2009)

The Avila Beach Health Study Phase 1: Reconnaissance Sampling Findings, Conclusions, and Recommendations. (July 1997) Volume 1: Baseline Human Health Risk Assessment. (May 1998)

The Avila Beach Health Study Phase 1, Volume 2: Environmental Monitoring. (May 1998)

Health Risk Assessment and Air Pathway Analysis for the Ballard Canyon Landfill, Santa Barbara County, Ca. (March 1999)

Screening Human Health Risk Assessment, Calculation of Soil Clean-up Levels, and Aquatic Ecological Screening Evaluation, Galilee Harbor, Sausalito, Ca. (May 1998)

Health Risk Assessment Due to Diesel Train Engine Emissions, Oakland, Ca. (June 1999)

Health Risk Assessment for Residual Mercury at the Deer Creek Facility, 3475 Deer Creek Road, Palo Alto, California. (July 1997)

Phase 2 Human Health Risk Assessment, Teledyne Inc., San Diego, Ca. (February 1997)

Human Health Risk Assessment, Teledyne Ryan Aeronautical, McCormick Selph Ordnance. Hollister, California. (December 1996)

Initial Phase Human Health Risk Assessment, Teledyne Inc., San Diego, Ca. (October 1996)

Human Health Risk Assessment, Ecological Screening Evaluation, and Development of Proposed Remediation Goals for the Flair Custom Cleaners Site, Chico, California (January 1996)

Human Health Risk Assessment for the X-3 Extrudate Project at Criterion Catalyst, Pittsburg, Ca. (November 1994)

Screening Health Risk Assessment and Development of Proposed Soil Remediation Levels at Hercules Plant #3, Culver City, Ca. (July 1993)

Ecological Screening Evaluation for the Altamont Landfill, Alameda County, Ca. (June, 1993)

Focused Ecological Risk Characterization, Hawaiian Electric Company, Keahole Generating Station Expansion, Hawaii (June 1993)

Human Health Risk Assessment for the Proposed Palima Point Space Launch Complex, prepared for the Hawaii Office of Space Industry (April 1993)

Ecological Risk Assessment for the Proposed Palima Point Space Launch Complex, prepared for the Hawaii Office of Space Industry (March 1993)

Human Health Risk Assessment for Current and Proposed Expanded Class II and Class III Operations at the Altamont Sanitary Landfill, Alameda County, Ca.
(March, 1993)

Screening Health Risk Assessment for the Proposed Expansion of the West Marin Sanitary Landfill, Point Reyes Station, Ca.
(March, 1993)

Health Risk Assessment for the Proposed Expansion of the Forward, Inc. Landfill, Stockton, Ca. (September 14, 1992)

Health Risk Assessment for the Rincon Point Park Project, San Francisco, Ca. Prepared for Baseline Environmental Consulting and the San Francisco Redevelopment Agency.
(August 10, 1992)

Health Risk Assessment for the South Beach Park Project, San Francisco, Ca. Prepared for Baseline Environmental Consulting and the San Francisco Redevelopment Agency.
(August 10, 1992)

Screening Health Risk Assessment and Development of Proposed Soil and Groundwater Remediation Levels, Kaiser Sand and Gravel, Mountain View, Ca. Prepared for Baseline Environmental Consulting (January 30, 1992)

Development of Proposed Soil Remediation Levels for the Marine Corps Air-Ground Combat Center, 29 Palms, California (May 30, 1991)

Preliminary Health Risk Assessment for the City of Pittsburg Redevelopment Agency, Pittsburg, California (May 29, 1991)

Military Bases

Dr. Greenberg has experience in conducting assessments at DOD facilities, including RI/FS work, preparation of health risk assessments, evaluation of hazardous waste sites and hazardous materials use at the following Navy sites in California: San Diego Naval Base; Marine Corps Air-Ground Combat Center, 29 Palms; Mare Island Naval Shipyard, Vallejo; Treasure Island Naval Station, San Francisco, Hunters Point Naval Shipyard, San Francisco, and the Marine Corps Logistics Base, Barstow. He worked with the U.S. Navy and the U.S. EPA in the implementation of Data Quality Objectives (DQO's) at MCLB, Barstow.

Examples

Review and Evaluation of the Remedial Investigation Report and Human Health Risk Assessment for the U. S. Naval Station at Treasure Island, Ca. (June 1999)

Screening Health Risk Assessment for the Proposed San Francisco Police Department's Helicopter Landing Pad at Hunters Point Shipyard, San Francisco, Ca. (September 1997)

Development of Proposed Soil Remediation Levels for the Marine Corps Air-Ground Combat Center, 29 Palms, California (May 30, 1991)

Health Risk Assessment for the Chrome Plating Facility, Mare Island Naval Shipyard, Vallejo, California (October 24, 1988)

Background Levels and Health Risk Assessment of Trace Metals present at the Naval Petroleum Reserve No.1, 27R Waste Disposal Trench Area, Lost Hills, California (August 12, 1988)

RCRA Facility Investigation (RFI) Work Plan of Lead Oxide Contaminated Areas, Mare Island Naval Shipyard, Vallejo, California. Prepared in conjunction with Kaman Sciences Corp. (August 14, 1989)

Hazardous Waste and Solid Waste Audit and Management Plan, Mare Island Naval Shipyard, Vallejo, California. Prepared in conjunction with Kaman Sciences Corp. (July 3, 1989)

Water Quality Solid Waste Assessment Test (SWAT) Proposal RCRA Landfill, Mare Island Naval Shipyard, Vallejo, California. Prepared in conjunction with Kaman Sciences Corp. (October 31, 1988)

Waste Disposal Facilities, Waste Haulers, Waste Recycling Facilities Report, Mare Island Naval Shipyard, Vallejo, California. Prepared in conjunction with Kaman Sciences Corp. (September 22, 1988)

Sampling and Analysis Plan, Health and Safety Plan, Site Characterization of Lead Oxide Contaminated Areas, Mare Island Naval Shipyard, Vallejo, California. Prepared in conjunction with Kaman Sciences Corp. (September 2, 1988)

Air Quality Solid Waste Assessment Test (SWAT) Proposal, Mare Island Naval Shipyard, Vallejo, California. Prepared in conjunction with Kaman Sciences Corp. (August 25, 1988)

Liquefied Natural Gas (LNG)

Dr. Greenberg assisted the CEC in the preparation of the "background" report on the risks and hazards of siting LNG terminals in California ("LNG in California: History, Risks, and Siting" July 2003) and consulted for the City of Vallejo on a proposed LNG terminal and storage facility at the former Mare Island Naval Shipyard. He has also conducted an evaluation and prepared comments on the risks, hazards, and safety analysis of the DEIS/DEIR for the City of Long Beach on a proposed LNG terminal at the Port of Long Beach (POLB) and conducted an analysis on vulnerability and critical infrastructure security for the CEC on this same proposed LNG terminal. He currently advises the CEC on the POLB LNG proposal on risks, hazards, human thresholds of thermal exposure, vulnerability, security, and represented the CEC at a U.S. Coast Guard briefing on the Waterway Suitability Assessment that included the sharing of SSI (Sensitive Security Information). He has presented technical information and analysis to the State of California LNG Interagency Working Group on thermal radiation public exposure criteria and safety/security at an east coast urban LNG terminal. (Both presentations are confidential owing to the nature of the material.) He has conducted numerous evaluations of the safety and hazards of natural gas pipelines for the CEC and has presented his findings and recommendations at public meetings and evidentiary hearings.

Infrastructure Security

Since 2002, Dr. Greenberg has been trained by and is working with the Israeli company SB Security, LTD, the most experienced and tested security planning and service company in the world. Since the events of 9/11, Dr. Greenberg has been the lead person for developing vulnerability assessments and power plant security programs for the California Energy Commission (CEC). In taking the lead for this state agency, Dr. Greenberg has interfaced with the California Terrorism Information Center (CATIC) and provided analysis, recommendations, and testimony at CEC evidentiary hearings regarding the security of power plants within the state. These analyses include the assessment of Critical Infrastructure Protection, threat assessments, criticality assessments, and the preparation of vulnerability assessments and off-site consequence analyses addressing the use, storage, and transportation of hazardous materials, recommendations for security to reduce the threat from foreign and domestic terrorist activities, perimeter security, site access by personnel and vendors, personnel background checks, management responsibilities for facility security, and employee training in security methods. Dr. Greenberg is the lead person in developing a model power plant security plan, vulnerability assessment matrix, and a security training manual for the CEC. The model security plan is used by power plants in California as guidance in developing and implementing security measures to reduce the vulnerability of California's energy infrastructure to terrorist attack. He has testified at several evidentiary hearings for the CEC on power plant security issues. He also leads an audit team conducting safety and security audits at power plants throughout California that are under the jurisdiction of the CEC. In addition to providing security expertise to the State of California, in August 2004, a team of experts led by Dr. Greenberg was awarded an 18-month contract by the State of Hawaii to update and improve the state's Energy Emergency Preparedness Plan and make recommendations for increased security of critical energy infrastructure on this isolated group of islands.

<u>Air Pathway Analysis</u>

Dr. Greenberg has prepared numerous Air Pathway Analyses and human health risk assessments, evaluating exposure at numerous locations in California, Hawai'i, Oregon, Minnesota, Michigan, and New York. He is experienced in working with Region IX EPA, the State of California DTSC, and the Hawai'i Department of Health Clean Air Branch in the application of both site-specific and non site-specific health risk assessment criteria.

Examples

Human Health Risk Assessment of Children's Exposure via the Air Pathway to Diesel Exhaust from School Buses (2007-2008)

Human Health Risk Assessment for the Open Burn/Open Detonation Operation at McCormick Selph, Inc., Hollister, Ca. (June 2003)

Air Quality and Human Health Risk Assessment for the Royal Oaks Industrial Complex, Monrovia, Ca. (January 2003)

Human Health Risk Assessment and Indoor Vapor Intrusion Assessment for the former Pt. St. George Fisheries Site, Santa Rosa, Ca. (October 2002)

Human Health Risk Assessment for the former Sargent Industries Site, Huntington Park, Ca. (July 2001)

Health Risk Assessment Due to Diesel Train Engine Emissions, Oakland, Ca. (June 1999)

The Avila Beach Health Study Phase 1: Reconnaissance Sampling Findings, Conclusions, and Recommendations. (July 1997) Volume 1: Baseline Human Health Risk Assessment. (May 1998)

The Avila Beach Health Study Phase 1, Volume 2: Environmental Monitoring. (May 1998)

Health Risk Assessment and Air Pathway Analysis for the Ballard Canyon Landfill, Santa Barbara County, Ca. (March 1999)

Human Health Risk Assessment, Teledyne Ryan Aeronautical, McCormick Selph Ordnance. Hollister, California. (December 1996)

Initial Phase Human Health Risk Assessment, Teledyne Inc., San Diego, Ca. (October 1996)

Human Health Risk Assessment for Current and Proposed Expanded Class II and Class III Operations at the Altamont Sanitary Landfill, Alameda County, Ca.
(March, 1993)

Focused Ecological Risk Characterization, Hawaiian Electric Company, Keahole Generating Station Expansion, Hawai'i (June 1993)

Human Health Risk Assessment for the Proposed Palima Point Space Launch Complex, prepared for the Hawai'i Office of Space Industry (April 1993)

Ecological Risk Assessment for the Proposed Palima Point Space Launch Complex, prepared for the Hawai'i Office of Space Industry (March 1993)

Human Health Risk Assessment Due to Emissions from a Medical Waste Incinerator, prepared for Kauai Veterans Memorial Hospital, Kauai, Hawai'i (1994)

Cancer Risk Assessment for the H-Power Generating Station, Campbell Industrial Park, Oahu, Hawai'i (1988)

Hazardous Materials Assessments, Waste Management Assessments, Worker Safety and Fire Protection Assessments, and Public Health Impacts Assessments

Dr. Greenberg also has significant experience as a consultant and expert witness for the California Energy Commission providing analysis, recommendations, and testimony in the areas of hazardous materials management, process safety management, waste management, worker safety and fire protection, and public health impacts for proposed power plant/cogeneration facilities. These analyses include the evaluation and/or preparation of the following:

- Off-site consequence analyses of the handling, use, storage, and transportation of hazardous materials,
- Risk Management Plans (required by the Cal-ARP) and Business Plans (required by H&S Code section 25503.5),
- Safety Management Plans (required by 8 CCR section 5189),
- Natural gas pipeline safety,
- Solid and hazardous waste management plans,
- Phase I and II Environmental Site Assessments,
- Construction and Operations Worker Safety and Health Programs,
- Fire Prevention Programs,
- Human health risk assessment from stack emissions and from diesel engines, and
- Mitigation measures to address PM exposure, including diesel particulates

Examples

- Almond 2 Power Plant Project, City of Ceres, Ca. 2009 – present. Public health.
- Watson Cogeneration Steam and Electric Reliability Project, Carson, Ca. 2009 – present. Public health.

<u>Occupational Safety and Health/Health and Safety Plans/Indoor Air Quality</u>

Dr. Greenberg has significant experience in occupational safety and health, having directed the development, adoption, and implementation of over 50 different Cal/OSHA regulations, including airborne contaminants (>450 substances), lead, asbestos, confined spaces, and worker-right-to-know (MSDSs). He has conducted numerous occupational health surveys and has extensive experience in the sampling and analysis of indoor air quality at residences, workplaces, and school classrooms. He is currently the team leader conducting safety and security audits at power plants throughout California for the California Energy Commission. Safety issues audited include compliance with regulations addressing several safety matters, including but not limited to, confined spaces, lockout/tagout, hazardous materials, and fire prevention/suppression equipment.

Examples

Occupational Safety and Health Audit and Air Pathway Assessment for a Composting System at the Cold Canyon Landfill, San Luis Obispo County (2010)

Review and Evaluation of Public and Worker Safety Issues at the proposed SES LNG Facility, Port of Long Beach. prepared for the City of Long Beach. (November 2005)

Confidential safety and security audit reports for 18 power plants in California. prepared for the California Energy Commission. (January 2005 through March 2006)

Report on the Accidental release and Worker Exposure to Anhydrous Ammonia at the BEP I Power Plant, Blythe, Ca. prepared for the California Energy Commission. (October 2004)

Investigation of a Worker Death in a Confined Space, La Paloma Power plant. prepared for the California Energy Commission. (July 2004)

Preliminary Report on Indoor Air Quality in Elementary School Portable Classrooms, Marin County, Ca. (December 1999)

Health Risk Assessment Due to Diesel Train Engine Emissions, Oakland, Ca. (June 1999)

Air Pathway Analysis for the Ballard Canyon Landfill. Submitted to the County of Santa Barbara, (March 1999)

Review and Evaluation of the Health Risk Assessment for Outdoor and Indoor Exposures at the Former Golden Eagle Refinery Site, Carson, Ca. (May 1998)

The Avila Beach Health Study Phase 1: Reconnaissance Sampling Findings, Conclusions, and Recommendations. (July 1997) Volume 1: Baseline Human Health Risk Assessment. (May 1998)

The Avila Beach Health Study Phase 1, Volume 2: Environmental Monitoring. (May 1998)

Phase 2 Human Health Risk Assessment, Teledyne Inc., San Diego, Ca. (February 1997)

Determination of Occupational Lead Exposure at a Tire Shop in Placerville, Ca. (April 1993)

Development of an Environmental Code of Regulations for Hazardous Waste Treatment Facilities on La Posta Indian Tribal lands, San Diego County, Ca. (August 1992)

Sampling and Analysis Plan, Health and Safety Plan, Site Characterization of Lead Oxide Contaminated Areas, Mare Island Naval Shipyard, Vallejo, California. Prepared in conjunction with Kaman Sciences Corp. (September 2, 1988)

Mercury Contamination

Dr. Greenberg has prepared and/or reviewed several human health and ecological risk assessments regarding mercury contamination in soils, sediments, and indoor surfaces. Dr. Greenberg served on the State Water Resources Control Board Bay Protection and Toxic Cleanup Program Advisory Committee from 1994 until the end of the program in 1999.

Examples

Review and evaluation of a human health risk assessment of ingestion of sport fish caught from San Diego Bay and which contain tissue levels of mercury and PCBs (November 2004 – present)

Screening Human Health Risk Assessment, Calculation of Soil Clean-up Levels, and Aquatic Ecological Screening Evaluation, Galilee Harbor, Sausalito, Ca. (May 1998)

Health Risk Assessment for Residual Mercury at the Deer Creek Facility, 3475 Deer Creek Road, Palo Alto, California. (July 1997)

Human Health Risk Assessment Due to Emissions from a Medical Waste Incinerator, prepared for Kauai Veterans Memorial Hospital, Kauai, Hawai'i (1994)

DECLARATION OF
Mark Hesters

I, **Mark Hesters,** declare as follows:

1. I am presently employed by the California Energy Commission in the Engineering Office of the Siting, Transmission and Environmental Protection Division as a Senior Transmission Planner.

2. A copy of my professional qualifications and experience is attached hereto and incorporated by reference herein.

3. I helped prepare the staff testimony on **Transmission System Engineering** for the **Palen Solar Electric Generating System Final Staff Assessment,** based on my independent analysis of the Application for Certification and supplement hereto, data from reliable documents and sources, and my professional experience and knowledge.

4. It is my professional opinion that the prepared testimony is valid and accurate with respect to the issue addressed therein.

5. I am personally familiar with the facts and conclusions related in the testimony and if called as a witness could testify competently thereto.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge and belief.

Dated: 8/1/13 Signed: ______________________

At: Sacramento, California

Mark Hesters

916-654-5049
mark.hesters@energy.state.ca.us

Qualifications

- Analyzed the reliability impacts of electric power plants for nine years.
- As an expert witness, produced written and oral testimony in numerous California Energy Commission proceedings on power plant licensing.
- Expertise in power flow models (GE PSLF and PowerWorld), production cost models (GE MAPS), Microsoft word-processing, spreadsheet and database programs.
- Contributing author to many California Energy Commission reports.
- Represented the Energy Commission in the development of electric reliability and planning standards for California.

Experience

Senior Electrical Engineer

2005-Present California Energy Commission, Sacramento, CA

- Program manager of the transmission system engineering analysis for new generator Applications of Certification.
- Lead the development of transmission data collection regulations.
- Overhauled the transmission data adequacy regulations for the Energy Commission's power plant certification process.
- Participated in the analysis of regional transmission projects.
- Technical lead for Commission in regional planning groups.
- Energy Commission representative to the Western Electric Coordinating Council Operations Committee.

Associate Electrical Engineer

1998–2005 California Energy Commission, Sacramento, CA

- Lead transmission systems analyst for power plant licensing under 12-month, 6-month and 21-day licensing processes.
- Provided expert witness testimony on the potential transmission impacts of new power plants in California Energy Commission licensing hearings.
- Authored chapters for California Energy Commission staff reports on regional transmission issues.
- Studied the economics of transmission projects using electricity production simulation tools.
- Analyzed transmission systems using the GE PSLF and PowerWorld load flow models.
- Collected and evaluated transmission data for California and the Western United States

Electric Generation Systems Specialist

1990–1998 California Energy Commission, Sacramento, CA

- Lead generation planner for southern California utilities.
- Analyzed electric generation systems using complex simulation tools.
- Provided analysis on the impact of resource plans on air quality and electricity costs for California Energy Commission reports.
- Developed modeling characteristics for emerging technologies.
- Evaluated resource plans.

Education

1985–1989 University of California at Davis Davis, CA

- B.S., Environmental Policy Analysis and Planning

DECLARATION OF
Jeanine Hinde

I, **Jeanine Hinde,** declare as follows:

1. I am presently employed by the California Energy Commission in the Environmental Office of the Siting, Transmission and Environmental Protection Division as a Planner II.

2. A copy of my professional qualifications and experience is attached hereto and incorporated by reference herein.

3. I helped prepare the staff testimony on **Alternatives** for the **Palen Solar Electric Generating System Final Staff Assessment,** based on my independent analysis of the Application for Certification and supplement hereto, data from reliable documents and sources, and my professional experience and knowledge.

4. It is my professional opinion that the prepared testimony is valid and accurate with respect to the issue addressed therein.

5. I am personally familiar with the facts and conclusions related in the testimony and if called as a witness could testify competently thereto.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge and belief.

Dated: August 6, 2013 Signed: Jeanine Hinde

At: Sacramento, California

JEANINE M. HINDE

Professional Experience

Planner II **February 2010–Present**

California Energy Commission, Sacramento, CA

Environmental Office of the Siting, Transmission, and Environmental Protection Division

Generalist skilled in research and analysis and preparing environmental assessments for siting of a variety of power plant projects filed with the Energy Commission. Analyzes project-related impacts on land use, agricultural resources, and visual resources. Evaluates project conformance with applicable laws, ordinances, regulations, and standards. Preparing the visual resources analysis for the Huntington Beach Energy Project, a 939-MW natural gas-fired plant that is proposed to replace the AES Huntington Beach Generating Station. Preparing the alternatives analysis for a project proposed to amend the previously approved 500-MW Palen Solar Power Project and change the technology from one renewable solar thermal technology to another. Prepared the alternatives analysis for a proposed 500-MW solar power tower project in the eastern Mojave Desert. Prepared the land use analyses for a 159-MW geothermal power plant in Imperial County and a 174-MW electrical generating plant in Ceres.

Environmental Analyst and Project Coordinator **2004–2009**

EDAW-AECOM, Sacramento, CA

Coordinated preparation of environmental studies to satisfy the California Environmental Quality Act (CEQA) and the National Environmental Policy Act and related permitting and regulatory requirements. Contributed to the preparation of regulatory compliance documents for projects addressing flood protection, wastewater management, water quality, habitat restoration, and urban development. As an assistant project manager, contributed to the preparation, technical review, and distribution of a variety of environmental compliance documents for projects that included a levee repair project on the Feather and Yuba Rivers, a levee seepage project on the San Joaquin River near the Sacramento-San Joaquin Delta (Delta), a wastewater treatment plant improvement project in Atwater, and a habitat restoration project adjacent to the middle Sacramento River. As an analyst, prepared environmental impact analyses for resource topics that included land use; agricultural resources; visual/aesthetic resources; public services, utilities and service systems; hazardous materials; recreation; and geology, soils, and mineral resources. Prepared mitigation monitoring and reporting program documents and assisted with fulfilling CEQA noticing and filing requirements.

Environmental Analyst, Independent Consultant **2003–2004**

Sackheim Consulting, Fair Oaks, CA

Researched and wrote the aesthetics analyses for the CEQA documents on related neighborhood electrical distribution projects in the Natomas and Elkhorn areas of Sacramento. Prepared a similar analysis for a project in Elk Grove. Assisted with the analyses addressing potential impacts on cultural resources and issues related to hazards and hazardous materials.

Environmental Specialist II **1986–1997**

Jones & Stokes Associates, Sacramento, CA

Evaluated impacts on land use, visual resources, and recreation for several state and federal projects, including a water supply management program in the East Bay, a project addressing long-term management of resources in the Delta and Suisun Marsh, and a military operations project at Camp Roberts. Provided technical review and coordinated preparation of report sections prepared by staff, and assisted with research and documentation of required federal, state, and local permits and approvals for inclusion in regulatory compliance plans.

Education

B.A. Geography, California State University, Chico

DECLARATION OF
Chris Huntley

I, **Chris Huntley,** declare as follows:

1. I am presently employed by **Aspen Environmental Group** as a **Senior Biologist**.

2. A copy of my professional qualifications and experience is attached hereto and incorporated by reference herein.

3. I helped prepare the staff testimony on **Biological Resources** for the **Palen Solar Electric Generating System Final Staff Assessment,** based on my independent analysis of the Application for Certification and supplement hereto, data from reliable documents and sources, and my professional experience and knowledge.

4. It is my professional opinion that the prepared testimony is valid and accurate with respect to the issue addressed therein.

5. I am personally familiar with the facts and conclusions related in the testimony and if called as a witness could testify competently thereto.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge and belief.

Dated: August 6, 2013 Signed: Chris Huntley

At: **Agoura Hills, CA**

CHRISTIAN S. HUNTLEY

Senior Associate/Biological Group Manager, Southern California

Academic Background

Graduate Studies, Biology, California State University Northridge
BA, Biology, University of California at Santa Cruz, 1992

Professional Experience

Mr. Huntley has 15 years of experience with Aspen conducting CEQA/NEPA analysis to support large scale electrical transmission and energy projects. He has extensive local experience in the Mojave and Colorado Deserts working on several large scale infrastructure projects including solar thermal, photovoltaic, and electrical transmission lines. Mr. Huntley has worked as an extension of CDFW staff to address effects to Mohave ground squirrel, desert tortoise, and bighorn sheep in the Lucerne Valley and for a suite of sensitive resources in southern California. Mr. Huntley has broad experience conducting biological assessments, managing large-scale construction and restoration projects, and supporting agency clients with permitting tasks including compliance with California Department of Fish and Wildlife (CDFW) 1600 and 2081 permits, US Fish and Wildlife Service (USFWS) Section 7 process, Regional Board 401 compliance, and US Army Corps (Corps) 404 permits. Recently Mr. Huntley worked as a member of an interagency team with the BLM, CDFW, and USFWS to identify and approve mitigation lands for desert tortoise, fringe toed lizards, burrowing owls, and State Waters. Supported by a solid background in biology and a practical knowledge of BLM procedures, CEQA/NEPA, USDA Forest Service requirements, regulatory consultation, and over a decade of construction management experience; Mr. Huntley is able to prepare and develop effective CEQA/NEPA documents and maintain objectivity during the regulatory process. Some of the relevant projects Mr. Huntley has worked on are described below.

Aspen Environmental Group...1998-present

Energy Experience

- **Palen Solar Energy Project (formerly PSPP Project), California Energy Commission, Biologist (2013-present).** Mr. Huntley is preparing the desert tortoise, rare plant, state waters, and burrowing owl impact analysis for the 3,947 acre solar energy project located east of Palm Springs California.
- **Hidden Hills Solar Energy Generating Station, California Energy Commission, Biologist (2012-2013).** Mr. Huntley prepared sections of the the biological resources analysis of the Staff Assessment for this 3,700 acre solar energy project located in Inyo County, California. Key issues included burrowing owl, desert tortoise, bighorn sheep, golden eagles and migratory birds.
- **Calico Solar Project (formerly SES Solar One Project), California Energy Commission, Biologist (2009-2010).** Mr. Huntley prepared the biological resources analysis of the Staff Assessment/EIS for this solar energy project proposed by Calico Solar, LLC. The proposed project would be located in San Bernardino County and included the construction and operation of an 850 MW Stirling engine solar generation facility, which would include approximately 34,000 SunCatcher solar dish Stirling systems on approximately 8,230 acres. Key issues include potential impacts to desert tortoise, Mojave fringe-toed lizard, Nelson's bighorn sheep, burrowing owl, and golden eagle, as well as large-scale modifications to existing drainages and interference with regional wildlife movement.
- **Palmdale Hybrid Power Plant, California Energy Commission, Biologist (2009-present).** Mr. Huntley is preparing the biological resources analysis of the Staff Assessment for this power generation project proposed by the City of Palmdale. The proposed project would be located in northern Los Angeles County and includes the construction and operation of a 570 MW hybrid combined-cycle and solar thermal electrical generation facility, which would include an approximate 333-acre plant site and a

35.6-mile transmission line to connect the project to the existing Southern California Edison (SCE) Vincent Substation, as well as four pipelines to transport water, gas, and wastewater (ranging from 1.5 to 7.4 miles in length). Key issues include potential impacts to Swainson's hawk, desert tortoise, Mojave ground squirrel, and golden eagle.

- **Rice Solar Energy Project, California Energy Commission, Biologist (2009-2010).** Mr. Huntley is contributing to the biological resources analysis of the Staff Assessment/EIS prepared for this solar energy project proposed by Rice Solar Energy, LLC (a wholly owned subsidiary of SolarReserve, LLC). The proposed project would include a 150 MW solar generation facility consisting of up to 17,500 solar-tracking heliostats, a central tower, and associated infrastructure and appurtenant structures. The solar field site would be located on approximately 1,410 acres of privately owned land in eastern Riverside County. In addition, a 10-mile 230 kV generator tie-line would be constructed to interconnect the project with Western Area Power Administration's existing Parker-Blythe transmission line. The new transmission line would traverse lands primarily under the jurisdiction of the Bureau of Land Management (BLM). The new transmission line would also require the construction of a new 4.6-mile access road, also largely located on BLM lands. Key issues include potential impacts to desert tortoise and golden eagle, and potential impacts to birds in general from the solar technology.
- **Amonix Solar Energy Development, California Department of Fish and Game, Biologist (2012).** Mr. Huntley worked as an extension of CDFG (CDFW) staff for this photo voltaic energy project in the Lucerne Valley. Formerly the Chevron Energy project; work on this facility was suspended in 2012.
- **Emergency Siting Team Power Plant Development, California Energy Commission, Compliance Project Manager.** For two years, Mr. Huntley's duties included management of technical staff for the completion of CEQA equivalent environmental permitting for over nine new emergency power plants, review of applicant submittals, drafting of Memoranda of Understanding with Chief Building Officials, conducting audits of building officials, and coordinating with affected agencies to resolve concerns with potential resource impacts. Other duties included maintaining contractor construction milestones, compliance monitoring and reporting, development of mitigation measures and conflict resolution for power plant compliance issues.
- **Coastal Power Plant Study, California Energy Commission, Deputy Project Manager/Biologist.** Mr. Huntley conducted biological surveys at 21 coastal power plants as part of the Energy Commission's coastal power plant study. Site visits characterized habitat within the footprint of the power plant, landscaping, and identified potential environmental and permitting issues associated with potential expansion of the power plants.
- **Hydroelectric Power Plant Inventory Study, California Energy Commission, Deputy Project Manager/Natural Resources Analyst.** Mr. Huntley coordinated a team that collected power and environmental data on over 200 hydroelectric power plants located in California. Physical power data included electrical output, system upgrades, water storage capacity and peaking availability. Environmental information included developing a data base addressing sensitive species issues, fish screens and ladders, monitoring parameters and a map of known hydroelectric facilities and barriers to anadromous fish passage. Mr. Huntley also obtained water use information on thermal power plants in support of the Energy Commission's bi-annual environmental performance report.
- **Topaz Solar Farm EIR, San Luis Obispo County, Issue Area Coordinator/Biologist (2009-2011).** Mr. Huntley served as the issue area coordinator for natural resources on this solar energy project proposed by Topaz Solar Farms, LLC (wholly owned by First Solar, Inc.). The proposed project would consist of a 550 MW solar photovoltaic energy generating facility on approximately 6,200 acres in the Carrizo Plain area of eastern San Luis Obispo County. Key issues included potential impacts to San Joaquin kit fox, jurisdictional drainages, vernal pools, rare plants, and nesting birds.

- **California Valley Solar Ranch EIR, San Luis Obispo County, Issue Area Coordinator/Biologist (2009-2011).** Mr. Huntley served as the issue area coordinator for biological resources on this solar energy project. The proposed project involved construction and operation of a 250 MW photovoltaic solar power plant in the unincorporated portion of eastern San Luis Obispo County. The project would be owned by High Plains Ranch II, LLC, a wholly owned subsidiary of SunPower Corporation Systems. A 3.5-acre substation and approximately 2.5 miles of 230 kV transmission would be required to connect to the existing Pacific Gas and Electric (PG&E) Midway to Morro Bay 230 kV transmission line. The project is one of two solar power plants proposed in the Carrizo Plain. Key issues include potential impacts to San Joaquin kit fox, blunt-nosed leopard lizard, and giant kangaroo rat.
- **Panoche Valley Solar Farm EIR, County of San Benito, Biologist (2010-present).** Mr. Huntley is technical support for this large-scale solar energy project. The proposed project would consist of a 420 MW solar energy generation facility on approximately 4,717 acres in the Panoche Valley of southeastern San Benito County. The facility would consist of 1,822,800 solar photovoltaic panels and associated infrastructure. Key issues include potential impacts to California tiger salamander, blunt-nosed leopard lizard, San Joaquin antelope squirrel, giant kangaroo rat, San Joaquin kit fox, San Joaquin coachwhip, mountain plover, golden eagle, northern harrier, burrowing owl, loggerhead shrike, and American badger. In addition, suitable habitat for the following special-status species exists at the project site: vernal pool fairy shrimp, Swainson's hawk, western spadefoot, California horned lizard, merlin, pallid bat, and western mastiff bat.
- **Pacific Wind Energy Project EIR, Kern County, Biologist (2009-2010).** Mr. Huntley oversaw the preparation of the biological resources analysis of this EIR evaluating a proposed 250 MW wind energy generation facility in the Mojave region of Kern County. The proposed project would be located on approximately 8,300 acres in the Tehachapi Wind Resource Area. Key issues include potential impacts to birds and bats from the wind turbines as well as potential impacts to desert tortoise, California condor, Swainson's hawk, and golden eagle.
- **Alta–Oak Creek Mojave Project EIR, Kern County, Biologist (2008-2009).** Mr. Huntley oversaw the preparation of the biological resources analysis of this Initial Study and EIR evaluating a proposed 800 MW wind development in the Tehachapi Wind Resource Area. The proposed project site consists of three distinct land areas comprising a total of approximately 10,750 acres. Key issues include potential impacts to birds and bats from the wind turbines as well as potential impacts to desert tortoise, California condor, Swainson's hawk, golden eagle, and Bakersfield cactus.

Transmission Line Experience

- **Downs Substation and Transmission Line Project IS/MND, California Public Utilities Commission (2010-present), Issue Area Coordinator/Biologist.** Mr. Huntley acted as issue area coordinator for biological resources on this transmission line upgrade to be completed by Southern California Edison in the Mojave Desert. Key issues included desert tortoise, Mohave ground squirrel, and burrowing owls. Portions of this project span lands administered by the BLM.
- **Devers–Palo Verde Transmission Line Project No. 2 EIR/EIS, California Public Utilities Commission (CPUC)/Bureau of Land Management (BLM), Issue Area Coordinator/Biologist (2005-present).** Mr. Huntley acted as issue area coordinator for biological resources on this 230-mile 500 kV transmission line upgrade to be completed by SCE. This project crosses key wildlife areas including the KOFA Wildlife Sanctuary, the San Bernardino National Forest, the Mojave and Sonoran Desert habitats, and sections of the Riverside Multiple Species Conservation Area. Currently, Mr. Huntley is supporting the biological monitoring team responsible for implementing CPUC and BLM monitoring requirements during construction of the project.

- **Tehachapi Renewable Transmission Project, CPUC/US Forest Service, Issue Area Coordinator/Biologist (2007-present).** Mr. Huntley is acting as the issue area coordinator and principal author for biological resources on this 500 kV transmission line project proposed by SCE in support of wind energy projects. This transmission line is 173 miles in length and includes two separate segments that cross the Angeles National Forest (ANF). Some of the key issues on this project include potential impacts to Mojave ground squirrel, desert tortoise, arroyo toads, California condors, spotted owl, and a host of forest sensitive plant and wildlife species. As part of the project, Mr. Huntley mapped over 190 riparian related features and completed extensive surveys of the ANF. Mr. Huntley managed an extensive biological staff and organized the completion of comprehensive botanical surveys for the proposed right-of-way. Other key issues involve the coordination with State Park, Forest Service, and resource agency staff.
- **Antelope Transmission Project, Segments 2 & 3 EIR, CPUC/US Forest Service, Issue Area Coordinator/Biologist (2006-2011).** Mr. Huntley acted as issue area coordinator for biological resources on this 500 kV transmission line proposed by SCE in support of wind energy projects. Key issues on this project include potential impacts to Mojave ground squirrel, California red-legged frog, burrowing owl, and rare plants. As part of this project, Mr. Huntley conducted focused surveys for arroyo toads and coordinated ESA compliance with the USFS and USFWS. As part of the project Mr. Huntley completed the BE/BA to comply with the provisions of the ESA and the Management Indicator Species Report for ANF compliance. Currently, Mr. Huntley provides technical assistance to monitoring staff.
- **El Casco Sub-Transmission Project EIR, CPUC, Issue Area Coordinator/Biologist (2006-present).** Mr. Huntley acted as issue area coordinator for biological resources and completed the impact analysis section of the EIR for this 17-mile sub-transmission line upgrade to be completed by SCE. This line is located in the Western Riverside Multiple Species Conservation Area and crosses areas supporting several federally protected species including least Bell's vireo, southwestern willow flycatcher, and Stephens' kangaroo rat. Currently, Mr. Huntley provides technical assistance to monitoring staff.
- **Antelope-Pardee Transmission Project EIR/EIS-BE/BA, CPUC/US Forest Service, Issue Area Coordinator/Biologist (2005-2010).** Mr. Huntley was the issue area coordinator for biological resources on this 500 kV transmission line upgrade to be completed by SCE. Key issues on this project included compliance with the US Forest Service Forest Plan and sensitive species including California condor, burrowing owl, and rare plants. Mr. Huntley reviewed and prepared the Biological Resource Section for the EIR/EIS, developed project alternatives, coordinated with Forest Service staff, and conducted sensitive species surveys for arroyo toad in support of this project. Currently, Mr. Huntley provides technical assistance to monitoring staff.
- **SCE Valley-Auld Power Line Project, CPUC, Environmental Monitor.** Conducted inspections of construction of this 11-mile power line upgrade for compliance with the project's Mitigated Negative Declaration mitigation measures and compliance plans. Other tasks included review of pre-construction compliance materials, maintaining inspection documentation, and coordination with SCE and its subcontractors.
- **Sunset Substation IS/MND and Biological Site Assessment, City of Banning, Biologist (2006-2007).** Mr. Huntley prepared the biology section of the IS/MND as a subcontractor to R. W. Beck. In addition, Mr. Huntley conducted burrowing owl surveys and managed surveys for Los Angeles pocket mouse at select locations along the proposed right-of-way.
- **Viejo System Project IS/MND, CPUC, Biologist.** Conducted biological surveys and completed the biological section of the Initial Study and Mitigated Negative Declaration for SCE's transmission line upgrade project.

Pipeline Experience

- **Santa Fe Pacific Pipeline, CPUC, Environmental Monitor.** Inspected construction of three petroleum distribution station sites for compliance with approved project mitigation measures and compliance plans.
- **Line 401 PG&E Redwood Expansion Project, CPUC, Lead Environmental Monitor.** Under contract to the CPUC, Mr. Huntley acted as Lead Environmental Monitor and supervised two environmental monitors in the field on the implementation of the CPUC's conditions of approval for construction of this 14-mile natural gas pipeline. Responsibilities included: supervision, guidance and development of environmental monitors, onsite field monitoring, compliance review and mitigation development of pre-construction plans, and mitigation compliance documentation. Other duties included review of variance and temporary extra work space (TEWS) requests; recommendations for CPUC issuance of Notices to Proceed with construction and variance approvals; approval of TEWS requests; preparation of weekly reports for all monitoring activity; and coordination with PG&E, construction managers and subcontractors, local municipalities, affected and interested agencies and the public.
- **Horsethief Creek Road Repairs Project, IS/MND and Biological Assessment, California Department of Water Resources, Biologist/Project Manager (2005-2009).** Mr. Huntley prepared the biological resource section and managed the completion of the IS/MND and the BA for construction of an all weather road at Horsethief Creek located near Lake Silverwood in San Bernardino County. Mr. Huntley also assisted DWR through formal consultation with the USFWS. The project was intended to provide an all-weather access to DWR facilities while avoiding impacts to federally endangered arroyo toads. Mr. Huntley also managed and conducted several of the sensitive species surveys required for this project including arroyo toad, two-striped garter snake, and southwestern pond turtles. Mr. Huntley managed the monitoring efforts at the site to comply with permit regulations identified by the Biological Opinion.

NEPA Experience

- **Littlerock Dam and Reservoir Restoration Project EIR/EIS-BE/BA, Palmdale Water District/US Forest Service, Deputy Project Manager/Biologist (2004-present).** Mr. Huntley is currently acting as deputy project manager and project biologist for the sediment removal activities associated with the Littlerock Dam and Reservoir in the ANF. Mr. Huntley is working to develop project alternatives for sediment disposal while avoiding impacts to federally endangered arroyo toads. Mr. Huntley is managing the sensitive species surveys for this project and completing the biological resources section of the EIR/EIS, Management Indicator Species Report, and BE/BA.
- **Newhall Ranch Project, California Department of Fish and Game, Biological Coordinator and CDFG Reviewer (2005-2009).** Mr. Huntley provided biological expertise and assisted CDFG staff in reviewing and revising the EIR/EIS for the proposed 6,000-acre Newhall Development Plan EIR/EIS in Santa Clarita. Primary issues concern the land use conversion of several thousand acres of wild lands and agricultural areas located in and adjacent to the Santa Clara River. This region is known to support numerous threatened and endangered species including least Bell's vireo, southwestern willow flycatcher, California condor, arroyo toad, unarmored three-spine stickleback, and San Fernando Valley spineflower. Other concerns associated with the development include wildlife movement corridors, and effects to riparian habitats. Mr. Huntley reviewed, commented and revised the environmental documents, scheduled and coordinated meetings with resource professionals and agency staff, and provided technical review of the document. Mr. Huntley will be assisting CDFG staff in the response to comments on the Draft EIR/EIS.

- **Matilija Dam Ecosystem Restoration Project EIR/EIS, US Army Corps of Engineers, Biologist.** Mr. Huntley conducted biological surveys and assisted in the completion of the EIS/EIR to assess impacts to sensitive biological resources located on Matilija Creek and the Ventura River downstream of the of the Matilija Dam. The analysis focused on potential impacts associated with dam removal on sensitive species known to occur on the Ventura River and the beneficial impacts of the restoration of spawning territory for the endangered Evolutionary Significant Unit of Southern Steelhead.
- **Fort Irwin Environmental Baseline Survey Reports, US Army Corps of Engineers, Project Manager/Biologist (2005).** Mr. Huntley managed the preparation of two Environmental Baseline Survey reports near Fort Irwin, San Bernardino County to support the land acquisition of over 95 parcels by the US Army for the Fort Irwin National Training Center. Mr. Huntley conducted site investigations, documented existing biological conditions and managed the preparation of the report.

Selected Technical Experience/Training and Certifications

- SWPPP trained 2006
- California Energy Commission Outstanding Performance Award, 2001
- CDFG Scientific Collecting Permit for pond turtle and garter snake.
- Certified Caltrans Horizontal Directional Drilling Inspector 2001
- Desert Tortoise Handling Workshop, Ridgecrest, California 2001
- CEC Expert Witness Training 2001
- Railroad Right-of-Way Safety Training 2002
- Small boat handling, licensed and certified since 1993
- Research Scuba-diving certification and training since 1989

DECLARATION OF
Gregg Irvin, Ph.D.

I, **Gregg Irvin**:

1. I am presently employed by Spectrus, Ltd. As the President.
2. A copy of my professional qualifications and experience is attached hereto and incorporated by reference herein.
3. I helped prepare the staff testimony on **Traffic and Transportation** and **Visual Resources** for the **Palen Solar Electric Generating System,** based on my independent analysis of the Application for Certification and supplements hereto, data from reliable documents and sources, and my professional experience and knowledge.
4. It is my professional opinion that the prepared testimony is valid and accurate with respect to the issue addressed therein.
5. I am personally familiar with the facts and conclusions related in the testimony and if called as a witness could testify competently thereto.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge and belief.

Dated: 07/31/2013 Signed: Gregg Irvin

At: Sacramento, California

July 2013

GREGG E. IRVIN, PH.D.
3731 Blossom Heath Road
Dayton, OH 45419
937-271-2715

EMPLOYMENT

2005-Present President, Spectrus, Ltd.
1996-2005 Principal Partner and Director of Operations, Mobium Enterprises, Inc.
1994-1997 Executive Director, Assistive Technologies Group
1996-2000 Employee Consultant, National Security Studies and Strategies Group, Science Applications International Corporation (SAIC), McLean, VA.
1993-1996 Assistant Vice President, SAIC, Dayton, OH.
1995-1996 Division Manager, Human Systems Technology Division, SAIC
1992-1995 Division Manager, Aerospace Systems Division, SAIC
1990-1991 Chief Scientist, Human Performance Technology Division, SAIC
1989-1990 Senior Scientist, Human Performance Technology Division, SAIC
1986-2000 Director, ICON Consultants, Birmingham, AL & Dayton, OH.
1985-1989 Senior Research Scientist, Systems Research Laboratories, Dayton, Ohio.
1984-1985 Visual Neurophysiologist, Vision Science Research Center, University of Alabama Medical School at Birmingham.

EDUCATION

1982-1984 National Eye Institute, Postdoctoral Fellow, Electrophysiology, Vision Science Research Center, School of Optometry, University of Alabama Medical School at Birmingham.
1981-1982 Postdoctoral Research Associate, Visual Neurophysiology, Department of Physiological Optics, School of Optometry, University of Alabama Medical School at Birmingham.
1981 Ph.D. Physiological Psychology, Syracuse University.
1976 B.A. Psychology, Syracuse University.

AWARDS/FELLOWSHIPS/DISTINCTIONS

1995-2003 Adjunct Faculty, Department of Biomedical and Human Factors Engineering, Wright State University, Dayton, OH.
1982-1984 National Eye Institute, Individual National Research Service Award
1979 Behavioral Neurobiology Scholarship, Cold Spring Harbor Research Laboratory, Syracuse University School of Engineering, Institute for Sensory Research.
1978-1980 Graduate Fellowships in Biopsychology (two awards), Syracuse University.
1977-1978 Graduate Fellowship in Physiological Psychology, Syracuse University.
1976-1977 Research Associate, Visual Psychophysics Laboratory, Syracuse University.

PROFESSIONAL SUMMARY

Dr. Irvin is a sensory neurophysiologist/ psychologist with a multidisciplinary background in visual science related fields including; applied experimental psychology, sensory perception, visual physiology and psychophysics, human systems interface, advanced image processing, human information processing, human perception and performance, mathematical visualization, neurobiology and human factors engineering.

Dr. Irvin is president of Spectrus, Ltd. Spectrus is a diversified small business providing services in engineering, human factors, neuroscience, physics, chemistry and life sciences. Spectrus develops advanced sensing technologies for indirect view multispectral and hyperspectral applications, which incorporate proprietary spectral mapping principles and (active and passive) frequency agile sensing capabilities. Spectrus also provides sensory modeling, image understanding, computational vision, specialized spectral sampling applications, advanced Human-System Interface development, and multidisciplinary sensing strategy services.

Dr. Irvin has strong leadership and managerial skills with a record of success in leading major research and development programs. This includes Air Force Research Laboratory programs developing physiologically based computer vision systems (stereovision, detection, and texture generation), low-observable technologies, and multispectral adaptive and passive camouflage, concealment and deception technologies. Efforts include developing and interfacing both head-steerable and advanced helmet mounted displays with integrated multisensor fusion capabilities for strategic aircraft, developing imaging architectures, information visualization technologies, and display technologies incorporating specialized chromatic, motion, and texture processing. Contributions to visual science include a model of developmental amblyopia, various models of human visual detection, studies of information transfer to primate visual cortex, and structure-function studies of neuronal morphology and visual information processing. Dr. Irvin's experience and qualifications span basic and applied advanced research and development, and technology transfer and application. Dr. Irvin has been featured in National Geographic "The Sense of Sight" and in a PBS NOVA documentary "The Disguises of War."

EMPLOYMENT EXPERIENCE

Spectrus, Ltd. (2005-Present)

President, Spectrus, Ltd. is an Ohio based Limited Liability Company established in January 2005 and provides consulting services to Government and industry. Dr. Irvin is the president and sole partner in Spectrus, Ltd. Spectrus represents a reorganization of Mobium Enterprises, Inc. and Mobium, Inc., for which Dr. Irvin was the president of both.

Representative Research and Development Efforts at Spectrus: Note: Multiple program summaries deleted due to classification issues.

***Security Lighting Development Program*.** (2011-). Consultant to Acuity Brands Lighting, Inc., Northeast Innovation Center (NEIC) for the development of RGB LED lighting hardware, software and supporting algorithms for visual, physiological and psychological disruption and disabling human performance effects. Lead developer for strategic architecture design and disruptive algorithm development to support a modular and adaptable security lighting system for a variety of industrial and government applications.

Solar Power Plant Develop for the California Energy Commission. (2010-). Providing analytic and modeling support to Traffic and Transportation, Visual Resources, and Biological Resources for the assessment of the visual impacts of heliostat mirror fields and solar power towers for proposed Solar Electric Generation Facilities (SEGF). Ongoing and past research includes determining the magnitude of visual and thermal effects (e.g., glint, glare, aesthetics, avian mortality), their level of significance, and the development of potential mitigating procedures for the proposed Calico, Rio Mesa, and Hidden Hills SEGFs.

Raytheon CV-22 Helmet Mounted Display. (2011) Subcontract to Raytheon for proposal development and review for the Boeing Defense Space and Security Division CV-22 Helmet Mounted Cueing System (HMCS). Activities included HDM architecture and functional capabilities for HMD interfaces, processing and control equipment, NVG capability, resolution, field of view, eye relief and exit pupil, display brightness and internal contrast ratios, luminance uniformities, and helmet tracking, slew and acceleration rates, latency and readout stability.

Mobium Enterprises, Inc. (1996-2005)

Principal partner, Director of Operations of Mobium Enterprises, Inc. Mobium is an Ohio C Corporation headquartered in Dayton, with offices in Alabama, Colorado, Massachusetts and New York. Mobium is active on local, state and national levels promoting strategic alliances between and among academe, industry, and government for the development of seminal technologies to enhance human perception and performance. Mobium seeks to reveal broader markets for the commercialization of human-systems technologies by emphasizing common needs and by emphasizing flexible modular technology that can be adapted to meet a variety of needs. Mobium is actively involved in a variety of joint technology development initiatives.

Mobium commercialization ventures include: a) a patented and licensed fluid jet array technology to reduce fluid precursor requirements to prepare thin films in semiconductor manufacturing, b) a differential ultra-violet filter technology (patent pending) for fabrication into optical filters using liquid and polymeric hosts, c) SWIFT – Stored Waveform Inverse Fourier Transform software package for the design of gradient index optical filters (patent in process), d) a plasma based ultra-thin film corrosion-inhibiting primer coating technology for stainless steel and aluminum to replace toxic chromium primer techniques (joint development venture in process). Additionally, Mobium is engaged in a software development project entitled MathWeb™. MathWeb™ is a Java-based tensor analysis and display package that is designed to run on distributed and heterogeneous networks and parallel computers.

Mobium provides expertise in advanced optical design and the analysis of multispectral imagery. Principals of Mobium have served as consultants to the U.S. Air Force on advanced human-system interfaces, and man-machine integration. Mobium personnel also have designed camouflage for the U.S. and European Armies and are aware of a broad range of programs sponsored by the DoD, NASA, DARPA, and other agencies concerned with the acquisition and interpretation of multispectral imagery. Mobium has developed a suite of sequential algorithms for enhancing the visualization and display of complex data sets and has examined the human factors that constrain the performance of integrated sensor suites in Uninhabited Aerial Vehicles.

Dr. Irvin's focus within Mobium is on the development of advanced sensing capabilities to facilitate human perception and performance. Dr. Irvin specializes in information extraction and enhancement through the application of advanced spectral sampling methodologies and the subsequent information transformation and representation for specialized human-in-the-loop applications.

Representative Research and Development Efforts at Mobium: Note: Multiple program summaries deleted due to classification issues.

Human-Systems Technology For Uninhabited Aerial Vehicle (UAV) Ground Stations. Provided support to Air Force Armstrong Laboratory Phase I SBIR program (AL/CF). The approach is based on a structured methodology for the development and commercialization of human-systems technology. The Technical Objectives are to: (1) identify human-systems interfaces (HSI) and virtual-reality (VR) technologies that require development to ensure the maturity necessary for a UAV VR control station or center, (2) propose a UAV VR concept demonstration supporting intelligent aiding, decision support, and mission management flexibility, and (3) identify issues and design tradeoffs involving human performance variables and VR properties.

Unmanned Combat Air Vehicle (UCAV) Program Support. Program Manager. Provided support to Raytheon E-Systems as a team member within the UCAV Ground Segment IPT to enhance the Unmanned Combat Aerial Vehicle (UCAV) IRAD project execution. Support focused on the: 1) study, analysis, identification and development of advanced Human Systems Interface (HSI) and Human Computer Interaction (HCI) functionality segmentation, 2) the inclusion of Automated Decision Aids to support HSI and HCI, and 3) analysis and identification of relevant technology domains pertinent to HSI technology insertion related to the UCAV Ground Station. Mobium provided trade study documents and support to the various Program Milestone and Technical Interchange Meetings.

Collaborative Commercialization, Research and Development Efforts with Syracuse University:

Dr. Irvin managed Mobium Enterprises extensive joint relationship with the Scalable Concurrent Programming (SCP) Laboratory at Syracuse University (SU) for technology development and commercialization through technology transfer. From 1999-2002 Mobium engaged in a variety of collaborative research and development programs with SU that include Distributed Real-Time Sensors Project and the Information Resiliency: Strategic Concepts for Assurance and Recovery Project. As a result of these collaborations Mobium maintained an office at the Syracuse University CASE (Computer Applications and Software Engineering) Center providing support to the SU research team on a daily basis. A brief description of the joint SU-Mobium initiatives and the resulting commercial technologies are as follows:

Distributed Real-Time Sensor Fusion. Project Manager. In a collaborative research effort with the SU-CASE center investigated the use of multiple sensors to increase the capability of intelligent system dealing with multi-sensor fusion and integration (MFI). Mobium developed distributed spectral-screening PCT algorithms for fusing hyper-spectral images in remote sensing applications. The algorithms provided intrusion tolerance from information warfare attacks using the framework of computational resiliency. Dynamically regenerative replication algorithms were integrated with replication-based fault tolerance mechanisms to respond to intrusion attacks and system failures. The utilization of application independent library technologies masked the details of communication protocols required to achieve dynamic replication and reconfiguration in distributed applications.

Computational Resiliency, Heterogeneous Reliable Applications. Project Manager. In conjunction with the Center for Systems Assurance (CSA) and the Computer Applications and Software Engineering Center at Syracuse University this initiative investigated the development of distributed computing systems to provide fault-tolerance through group communication based active replication, automatic reconfiguration and recovery from the attacks and failures, and load balancing over heterogeneous resources. The research focused on intrusion detection, high-confidence design, network security, information assurance, computer forensics, process migration, split/merge of processes, and camouflage techniques to achieve reasonable resiliency goals within defined predictive analytical models of performance assessment.

Remote Sensing Multispectral Image Exploitation. This joint initiative involves the development of advanced parallel algorithms and display technologies to facilitate the real-time data acquisition and exploitation of multispectral image streams. The resulting technology suite, currently in the final stages of development for proof-of-concept demonstration, provides the basis for commercial products to support various terrestrial and airborne remote sensing applications (e.g., land resource management, agricultural and crop monitoring, military target identification), and medical applications (e.g., multispectral endoscopy and ophthalmology). This initiative involves the development of: a) adaptive temporal-spectral real-time multispectral image acquisition, b) optimized real-time decorrelation and compression algorithms, c) advanced human-system interface for physiologic information bandwidth optimization, and d) the development of supporting distributed and concurrent computer architectures. A multispectral image exploitation algorithm suite is currently under development to support the Spectral Embedding Methodologies R&D Program for the development of next-generation sensor hardening for direct and indirect-view airborne military optical systems.

Cyber-Eye™ Multispectral Camera Systems. A natural outgrowth of the collaboration for multispectral image exploitation was the development of a multispectral imaging camera system to support laboratory and field data acquisition. The result was the design and development of a family of high-speed digital multispectral imaging systems supported by high performance multiprocessing. The Cyber-Eye camera series includes multispectral digital imaging systems capable of real-time 12 spectral band image acquisitions and processing at 120 frames per second. The commercialization of these systems is in process. A Cyber-Eye system was developed for the Air Force to support the Spectral Embedding Methodologies program referenced above.

MathWeb™. MathWeb is a tensor-based applications development product specifically designed to support distributed concurrent and heterogeneous computing environments. This commercial product has been used in a variety of government and industry applications. One such application in the final development stages is an integrated suite of image processing tools for real-time processing of multispectral and hyperspectral sensor data, image exploitation, and unique visualization techniques for human-system interface. Both the Cyber-Eye Multispectral Camera Systems and I-STORM incorporate MathWeb as the basis operating system.

Assistive Technologies Group (1994-1996)

ATG develops consortia and strategic alliances, and serves as a technology and information broker to support biobehavioral technology transfer initiatives.

Dr. Irvin founded and served as executive director of the Assistive Technologies Group (ATG). ATG's mission is to develop and transition advanced federal technologies to a sustainable national industrial capability within the commercial market of assistive technologies for Americans with disabilities. As a not-for-profit company, ATG served to promote and participate in research on limitations to human perception and performance that are due to disabling physiological or environmental conditions, and, promote and participate in the development of technology that can restore or enhance otherwise impaired human perception and performance. ATG nurtured links between research and technology development by promoting biobehavioral research that is commensurate with engineering descriptions and specifications. ATG is active on local, state and national levels to promote strategic alliances between academe, industry and government to develop seminal technologies that can identify or ameliorate biomedical constraints on human behavior. ATG has established a Memorandum of Agreement

(MOA) with the Federal Laboratory Consortium for Technology Transfer, Midwest Region (FLC-MW) to define and translate assistive technology requirements, identify and select federal technologies for transfer, and, to develop, prototype and produce assistive technologies that are economically viable and commercially sustainable. ATG is a member of the FLC-MW Roundtable and serves as the Internet Gatekeeper for technology transfer for assistive technologies.

Past Research and Development Efforts at ATG:

Needs Assessment for Federal Technology Transfer for Individuals with Developmental Disabilities. Project Manager. State Grant Plan 95-6 Ohio Department of Mental Retardation and Developmental Disabilities, Ohio Developmental Disabilities Planning Council (ODDPC). This effort seeks to expand the technological solutions to selected problems encountered by individuals with disabilities. End user requirement assessments and technology evaluations are conducted to produce descriptions of abilities and disabilities in a classification framework that can provide appropriate requirement-technology linkages. Mechanisms of translation are applied between engineering and biobehavioral domains for the analysis of specific functional life activities and the selection of potential supporting technologies. The approach seeks to reveal how common dimensional descriptions of both human and system capabilities and limitations can facilitate purposeful technology synthesis. The approach will demonstrate how a variety of technologies and their combination can produce a general purpose and modular technology bundle that can be easily adapted to special purpose device implementations that fulfill a variety of functional activities and achieve maximum population inclusion.

Ohio Initiative in Human Systems Technology. Project Manager. State Grant Tech-96-035 Ohio Department of Development, Ohio Science and Technology Council (ODOD/OSTC). This effort developed support for a center of excellence for the advancement of the emerging industry of assistive human-systems technology and seeks to establish the State of Ohio on the leading edge of this industry. The Human Systems Technology Center would provide business access to state-of-the-art biobehavioral research and technology performed in-house or obtained through linkages with federal laboratories, universities and other institutions; provide access to education and training programs, conferences, seminars and other networking opportunities; and provide access to services that reveal the biobehavioral needs of the general population and that translate these needs into commensurate technology solutions. Activities include the identification of; the needs and market for human-systems technology; the resources for human-system technology development; mechanisms for matching needs and resources in human-systems technology, and; government, industry and academic partners.

Employee Consultant, Science Applications International Corporation (1996-2000)

Provided consulting services to the National Securities Studies and Strategies Group at SAIC, McLean, VA. Corporate support includes business development, facilitating inter-corporation strategic alliances, developing marketing strategies and supporting various marketing initiatives. Technical support is also provided to select programs. A recent program win included the Crew Centered Design Technology (CCDT) Advanced Development Project at AFRL/HE

Past Employee Consulting Efforts at SAIC:

Sensor Support to Special Operations Forces. Provided support to the Defense Advanced Research Projects Agency, Sensor Technology Office (DARPA/STO) for the identification of advanced sensor technologies to support the Special Operations Commands. As the lead for sensor technology assessment and applications support was provided to define current sensor capabilities and limitations across the full spectrum of available and in-development sensing technologies. The program goal was the identification of advanced sensing technologies that can facilitate the mission requirements of the Air Force, Army, Navy, Marine, and Joint Special Operations Forces.

NATO Special Group of Experts in Camouflage, Concealment and Deception. Provided invitational support to NATO AC/243, Special Group of Experts in Camouflage, Concealment and Deception (SGE/CCD), Working Group A: Measurements and Backgrounds, for the conduct of a three year multi-national program entitled "Background Characterization for Camouflage Pattern Development." Program support was provided for: the development of multispectral camouflage patterns that accurately replicate background texture, the identification of US multispectral camouflage capabilities, test site selection and characterization metrics, test design and performance evaluation metrics, and test conduct to the Chairman of NATO AC/243 SGE/CCD WG-A at the US Army CECOM, Research Development & Engineering Center, Night Vision & Electronic Sensors Directorate (AMSEL-RD-NV-CD-CCD).

Survivability Integration (SURVINT) - Force Survivability and Weapons of Mass Destruction. Provided support to the Defense Special Weapons Agency (DWSA), Electronic Systems Directorate, Survivability Assessments Division for the integration of DWSA research efforts to maximize the survivability of US forces and associated systems and infrastructure against a variety of wartime threats, to include conventional weapons, improved conventional weapons, and weapons of mass destruction. A prototype Survivability Simulation and Planning System (SSPS) was developed for the interactive analysis and planning of the employment of extant and future survivability assets to address global wartime contingencies at the unit/airbase, Joint Task Force, and Theater levels. Responsibilities included scenario definition, technology identification, selection of signature and force-on-force models, and task leadership for visual, electro-optic and thermal countermeasures and modeling.

Science Applications International Corporation (1989-1996)

Corporate responsibilities included serving as an SAIC Assistant Vice President, management of the Human Systems Technology Division, and direct supervision of the Human Performance Data Management Division. Functions included Corporate, Group and Division financial and technical planning, personnel management, marketing, and Program Management for multiple technical efforts. Managed all human factors and human engineering support for the Armstrong Laboratory, Human Engineering Division, Crew Systems Integration Branch (AL/CFHI) Strategic Integration Design Evaluation Facility (SIDEF) support contract (5yr, 16M) at Wright-Patterson Air Force Base, Ohio. The Air Force Service Effort Description Area for SIDEF is Human Systems Interface: Performance Assessment and Design. The SIDEF research objective is to: a) apply multiplace/distributed human-systems design research, evaluations and assessment tools to prototype crew station designs and systems for evaluation in current (B-1, B-2) and future automated multiplace cockpits, b) assess impacts of crew aiding technologies on multiplace crew performance, workload and situational awareness, and c) conduct information requirements analysis and conceptual workstation interface designs for distributed information warfare architectures. The Multiplace and Distributed Crew Systems

Technologies Program functional research and development areas include: a) Crew-Centered Aiding, Advanced Reconnaissance, Surveillance, and Target Acquisition, b) Design Assessment for Advanced Crew Systems, c) Crew Systems for Information Management and Display Technologies, d) Systems Engineering Design and Technical Analysis.

Past Research and Development Efforts at SAIC:

B-1 Sustaining Research Support Program. Human Factors lead. This Human-Systems Interface (HSI) Research Program provided the AL/CFHI Multi-Operator Design Assessment Laboratory (MODAL) and the B-1 SPO (ASC/YD) with a rapid response capability to address current and emerging issues by providing the Human Factors and Engineering expertise to address Multi-Operator Crew Aided Systems problem domains in the context of a B-1 research simulator. Human Factors research activities included: the review and analysis of multiplace/distributed human-systems design research, evaluations and assessment tools; conceptual development and prototyping of components to support crew station designs and systems for evaluation in current B-1 and future automated multiplace cockpits; development and assessment of crew aiding technologies on multiplace crew performance, workload and situational awareness; and the conduct of information requirements analyses and conceptual workstation interface designs for distributed information architectures.

B-2 Sustaining Research Support Program. Human Factors lead. This Human-Systems Interface (HSI) Research Program provided the AL/CFHI Multi-Operator Design Assessment Laboratory (MODAL) and the B-2 SPO with a rapid response capability to address current and emerging issues by providing the capability to prototype crewstation designs and multiplace and distributed crew systems, and provided the human factors capabilities to address Multi-Operator Crew Aided Systems and Human System Interface research for multiplace cockpit control and display-related issues in the context of a B-2 research simulator and associated research tools.

Multispectral Aerosol Obscurant Effects on Synthetic Aperture Radar Target Acquisition Program. Project Manager. Provided support to the U. S. Army Edgewood Research, Development and Engineering Center, and the Naval Surface Warfare Center, Warfare Systems Department, Countermeasures Division, Research Branch to examine human target acquisition performance using Synthetic Aperture Radar (SAR) systems in an air-to-ground offensive when defensive multispectral obscurants (MSO) are deployed. A high-resolution ground mapping radar simulator and specialized image processing algorithms were used to conduct experiments to determine separable MSO attenuation and backscatter effects on man-machine system performance during SAR target acquisition and designation processes. The research addressed multiple target classes in operationally representative simple and complex background target environments. Research objectives included development of optimized image processing algorithms to maximize an operator's ability to "see-through" various obscurant countermeasures, and, development of optimized obscurant designs.

Tactical Decision Aid Human Performance Modeling and Analysis Program. Project Manager. Provided support to the Wright Laboratory, Avionics Directorate, Electro-Optics Branch (WL/AARI) and the Phillips Laboratory, Geophysics Directorate, Atmospheric Sciences Division (PL/PGA) in the development, implementation and integration of visual detection, identification and recognition ranging algorithms to enhance the various Tactical Decision Aid (TDA) models (Infrared, Direct View, Electro-Optical and Television TDAs') predictive capabilities. The visual system algorithms were based on a space/spatial frequency pyramid representation incorporating physiologic adaptive luminance and contrast gain control mechanisms. Laboratory analysis and psychophysical experimentation supported the parameterization and subsequent integration into the Air Combat Targeting Electro-Optical Simulation Program (ACT/EOS) mission planning effort. The project provided Air Force mission planners accurate human performance predictive capabilities of target data embedded in Geographic Information Systems (GIS) and Global Positioning Systems (GPS) derived reference environments combined with satellite imagery and the simulation of how real-world weather effects various sensor imaging capabilities. The approach allowed for high value complex target classes and complex backgrounds to be incorporated into the various TDA models and the ACT/EOS with accurate predictive modeling capabilities.

Camouflage, Concealment, Deception and Obscuration (CCDO) Program. Project Manager. Providing human factors, human engineering, and research technical-analytic support to AL/CFH for concept development and both laboratory and field, test and evaluation of various CCDO techniques to support Air Base Operability and Survivability (ABOS) initiatives. Research includes the design, development, and implementation of an advanced Texture Image Processing System (TIPS) to enable the conduct of research for the development and evaluation of spatial camouflage and disruptive patterns. Multispectral texture generation algorithm concepts are being developed for the development and evaluation of site-specific urban and foliated spatial camouflage patterning.

B-2 Cursor Design and Mechanization Program. Sponsored by the B-2 Systems Program Office (SPO), this program supported human factors research in the AL/CFHI B-2 simulator for the development and optimization of display cursor design and mechanization. Responsibilities included cursor mechanization design, and experimental design and evaluation in B-2 mission relevant contexts for Synthetic Aperture Radar (SAR) updates, and using a simulation of the Global-Positioning Aided Targeting System (GATS).

Fixed Facility Camouflage, Concealment and Deception Joint Test and Evaluation (JCCD): Test Design. Project Manager for Program Test Design. Provided support to the Office of the Secretary of Defense, Under Secretary of Defense, Acquisition, (OSD USD(A)), Weapons Systems Assessment, Special Test and Evaluation Program (WSA/STEP) and the JCCD Joint Test Force for the development and conduct of the JCCD Test and Evaluation program (4yr, 32M). Developed JCCD Program Test Design (PTD) document. This defined program test objectives, methodology, procedures, scenario requirements, and all test site requirements including ground and airborne instrumentation, data reporting formats, flight operation requirements, and environmental and safety assessments. Subsequent support was provided to develop the Program Test Plan, Program Database Management and Analysis Plan, Target Characterization Requirements, and Program Human Factors Plan. Created the Human Performance Data Management Division, to support the ongoing JCCD program conduct for the quantitative evaluation of the effectiveness of CCD against all modern threat weapons systems.

Laser Guided Weapons Countermeasures Program. Sponsored by the Defense Weapons Systems Agency and the Air Force Aeronautical Systems Center (ASC/YQ), this program is developing active countermeasure (CM) systems to defeat threat laser guided weapon systems. Responsibilities included analysis, development and systems specification for laser designation detection and signal processing, CM response algorithms, CM laser transmitters, beam transport systems, end optics, damage minimization zones, and evaluation of the adaptability of the proposed CM defensive systems against future precision guided weapon threats.

Deceptive Technique Evaluation Program. Project Manager. Camouflage, Concealment and Deception (CCD) research efforts involved (a) the development and evaluation of hybrid CCD techniques (b) the development and evaluation of aircraft masking patterns (c) experimentation on the perceptual basis of the deceptive effectiveness of 2-D decoys and masking patterns (d) luminance and chrominance tonedown strategies for air base facilities (e) large scale static and dynamic visual disruption techniques, (f) fixed facility decoy and signature reduction and enhancement techniques, and (g) requirements specifications for spectral properties of false operating surfaces. Supported various CCD field evaluations including Dusty Demo, Gallant Eagle and Creek Shadow. Responsibilities included all aspects of (a) data acquisition and analysis for visual, infrared and radar treatments (b) aircrew pre-brief, de-brief and questionnaire development, and (c) radar bomb scoring data and head-up display (HUD) analysis for various fighter aircraft sensor imagery.

Ideal Masking Pattern Program. Project Manager. Under Air Force Armstrong Laboratory, Directors Funding initiative developed a biologically-based parallel image processing system to compute optimal 2-dimensional spatial camouflage and masking patterns. The resulting Advanced Texture Image Processing System (ATIPS) combines spatially global (Fourier), spatially local (physiologic) and traditional image processing technologies into a common processing architecture for the rendering of ideal camouflage/ masking designs for any arbitrary environmental scenario.

Aim Sight Phase I Development Program. Human Systems Interface (HIS) lead designing, interfacing, and demonstrating advanced man-machine interfaces (MMI) in a full mission simulation for the B1-B and advanced strategic aircraft. Developed multisensor integration concepts and crew coordination and control integration concepts for a head-steerable FLIR (forward-looking infrared) imaging system applied to a night vision airborne reconnaissance search task and weapons delivery for strategic relocatable targets. Developed a virtual environment MMI demonstration capability provided to the Visually Coupled Airborne Systems Simulator (VCASS) Super Cockpit Program.

Optical Countermeasures (OCM) Program. Project Manager. Provided technical and experimental direction in the development, analysis and evaluation of various laser countermeasures against the human visual system and sensor/weapons systems. Research was conducted to evaluate OCM effects on aircrew performance including aircraft control, visual acuity, contrast sensitivity, visual perimetry and target detection, identification, and designation. Research efforts included the development of an interactive flight simulation capability for the evaluation of laser OCM on aircrew performance within the context of mission relevant scenarios for air base attack operations. Developed first approved protocol for direct intraocular laser exposure in humans to support research efforts.

The 4th Space Warning Squadron (4 SWS), Mobile, Survivability Improvement Program. Sponsored by the Defense Weapons Systems Agency, Strategic Command and Control Division (DWSA/NASC) this program improved the survivability of the Air Force Space Command, 21st Space Wing, 4 SWS during deployed ballistic missile warning operations. The program included analysis of exploitable identifying signatures for all operational phases and deployment locations across both the strategic and tactical conflict engagement spectrum to develop a comprehensive multispectral deceptive program. Responsibilities included task leadership for signature analysis and deceptive technique development for visual, thermal, radar, electronic, acoustic, and olfactory signature reduction.

ACE and SHAPE Alternate War Headquarters Deceptive Practices Programs. Provided technical analysis and test planning support to the Defense Nuclear Agency for both the Allied Command Europe (ACE), and the Supreme Headquarters Allied Program in Europe (SHAPE) Alternate War Headquarters Deceptive Practices Programs (ACE AWHQ/DPP, and SHAPE AWHQ/DPP). Developed and provided various CCD concepts, technologies and techniques for AWHQs (both existing and interim) and supported subsequent field testing for HQ AFCENT at the NATO Camouflage of Mobile Command and Control Elements (CAMCOE Phase II and III) exercises to evaluate CCD effectiveness.

Project CABLE. Project Manager. In conjunction with WL/AARI, ASC/YQ, and AL/CFH established a Memorandum of Understanding with the German Military Defense, Forschungsinstitut fur Optik (FGAN-FfO), and Industrieanlagen - Betribsgesellschaft (IABG/WVT), Military Installations and Image Processing to conduct the Joint German-US Project CABLE, (Camouflage of Air Bases, example Leipheim) to implement and field test various CCD measures designed to defeat airborne infrared acquisition systems. Developed program test plan for CCD treatments, data acquisition and analysis, sensor and imagery analysis, pilot pre-brief, interview and questionnaire. Developed and implemented visual/thermal decoys and masking patterns for field-test and conducted subsequent laboratory analysis and experimentation with field imagery.

Multispectral Smoke Obscuration Modeling. Project Manager. Developed a Silicon Graphics based flight simulation capability for the Aeronautical Systems Center, Integrated Engineering/Technology Management Directorate, Crew Systems Branch (ASC/EN) to research Infrared Smoke Obscuration Requirements for the denial of air to ground target acquisition. Conducted research program using simulated LANTIRN imagery to evaluate target acquisition as a function of airborne obscurant density using an equivalent contrast reduction technique.

Additional research efforts on SIDEF with significant support roles include:

Concept I Demonstration. Human factors lead in the development and implementation of image extraction algorithms for evaluating the performance of computer vision systems for image recognition and Automatic Target Cueing (ATC) using synthetic aperture radar (SAR) imagery. In support of the Strategic Relocatable Target (SRT) Program developed a Signal Detection Theory paradigm to evaluate man-machine system performance for real-time air-to-ground SRT acquisition using the Strategic Avionics Battle-management Evaluation Research (SABER) simulator.

Advanced Target Acquisition System (ATAS) Conceptual Studies. Assisted Strategic Air Command (SAC) in establishing system performance requirements for ATAS deployment concepts and configurations, and evaluate ATAS performance with flight simulation experimentation for various SAC missions.

Radar Warning Receiver Human Factors Study. Designed and conducted research to evaluate human performance, situation awareness and workload for an integrated vs. stand-alone radar warning receiver in the B1-B defense management system configuration.

Strategic Mission Analysis. Developed a B-1 relocatable target mission, conceptual control and display concepts, and supported simulation studies to evaluate human-system performance.

Automatic Map Cueing Evaluation. Conducted B1-B OSO task analysis, mission decomposition and development, and conduct experiments to evaluate new Automatic Map Cueing system.

Phase II Color Research. Designed and tested man-machine interface (MMI) concepts and advanced defensive display color formats for the B1-B Defensive System Officer's displays.

Additional research has included support to the Aeronautical Systems Center (ASC/XR) Specialized Short Term Development Planning Support contract. Support was provided to the Human Systems Division (HSC/XR):

a) In visual requirements analysis and future technology assessment for the ***Tactical Night Vision Program***, and the ***Night Vision Goggles Requirements Analysis and Technology Assessment Program***. Contributions included requirements analysis, technology assessment, mission analysis and trade studies for future night vision goggle and integrated helmet mounted display/sight systems for night low level visual navigation, targeting and weapon delivery.

b) In visual requirements analysis for the ***Close Air Support/Battlefield Air Interdiction and Reconnaissance Night Attack Sensor System Program***. Contributions included determining Tactical Air Command vision requirements for fixed and head-steered navigation, targeting and information (NTI) systems (both HMD and NVG targeting) to support Army operations with 24-hour CAS, BAI, and RECCE missions for the F-16.

Past efforts also included a compartmentalized program for the design, research and development for advanced sensor and display technology applications combining sensor fusion, real-time physiologic image processing, and multispectral hybrid display applications.

Systems Research Laboratories (1985-1989)

Concurrent program manager for the Optical Countermeasures (OCM) and the Camouflage, Concealment and Deception (CCD) programs at the Armstrong Aerospace Medical Research Laboratory (AAMRL) under the Human Engineering Support contract. While managing these two programs grew the full-time technical support staff from one to seven individuals. Management responsibilities included budget control, proposal development and directing a team of human factors and engineering personnel. Research responsibilities included problem definition, preparation and review of experimental protocols, conducting experiments, resource control and allocation, and documentation of results.

OCM research assessed visual performance for various aircraft and weapons systems to develop effective deployment and defense strategies for various optical countermeasure techniques. Direct interocular exposure to various threat lasers dominated the research programs. These included: dynamic target acquisition and visual tracking performance, measures of transient visual field losses, the effects of windscreens and personnel protective visors, spectral analysis of various optical media, quantification of beam profiles and scatter effects, and measures of spatial contrast sensitivity in the presence of structured exposures as a function of wavelength, target contrast, and adaptation level. Developed a review concerning metrics of eye safety with respect the thermal, photoacoustic, and photochemical hazards involved in laser exposure.

CCD research involved the development and evaluation of camouflage, concealment and deception related practices. This included active and passive aircraft visual signature reduction, air base luminance and chrominance tonedown strategies, the use of 2-D silhouette decoys, and deceptive 2-D masking and shape disruptive patterning analysis. Research efforts also included developing a physiologically based vision model to predict detection thresholds of arbitrary space-time separable stimuli using a 4-D foveated space/spatial-frequency Gabor pyramid representation. Developed a new methodology for the derivation of optimal masking patterns and camouflage design based on psychophysical theories of visual system processing of pattern information.

University of Alabama at Birmingham Medical School (1984-1985)

Visual Neurophysiologist, Vision Science Research Center. Conducted detailed measures of spatial modulation transfer functions of physiologically identified neurons in the lateral geniculate nucleus (LGN) of Galago crassicaudatus, a prosimian primate. Difference-of-Gaussians modeling of center-surround organization for single-cell spatial contrast sensitivity functions was used to test current models of spatial receptive-field organization and to derive parameters specifying receptive-field spatial and sensitivity attributes for analysis. The results demonstrated fundamental differences in the spatial organization of the W, X, and Y LGN cell classes which mediate the relay of visual information to primary visual cortex. A comparison with other visual processing and physiologic response characteristics provided a better understanding of spatial processing in the primary visual pathway.

EDUCATIONAL EXPERIENCE

National Eye Institute Postdoctoral Fellow (1982-1984)

University of Alabama Medical School at Birmingham, Vision Science Research Center. Developed technologies and instrumentation necessary to conduct intracellular recording with horseradish peroxidase (HRP) staining techniques. Developed and implemented procedures for manufacturing and beveling glass capillary micropipettes, extracellular and intracellular recording techniques and instrumentation, physiological classification of neuronal response properties, iontophoresis of HRP, histological processing and histochemical staining of brain tissue, and morphological reconstruction of neurons. These inclusive techniques allowed the recovery of the complete detailed morphology of individual neurons in the Superior Colliculus of the tree shrew after physiological classification in the temporal and spatial domains using computer driven stimuli. These structure-function studies allowed a direct comparison between the information processing capacities of individual neurons and their specific morphological structure. Analysis examined relationships between physiologic response properties, cellular morphology, and connectivity.

Postdoctoral Research Associate, Visual Neurophysiology (1981-1982)

University of Alabama Medical School at Birmingham, Department of Physiological Optics. In a collaborative effort with Vanderbilt University Departments of Cell Biology and Psychology examined the receptive-field organization of relay cells in the lateral geniculate nucleus (LGN) of both normal and monocularly deprived Galago, a prosimian primate.

The studies in normal Galago demonstrated that W, X, and Y relay cells are segregated by LGN laminae in accordance with cell size distributions. Additionally, cells histologically localized to the interlaminar zones (ILZs) of the LGN exhibit W-cell response properties; a new finding consistent with the similar morphology and anatomical connections that ILZs share with W-cell LGN laminae across mammalian species. This significant discovery strongly supports the conclusions that: a) both the ILZs and koniocellular layers in the Galago LGN convey W-like visual information from retina to cortex, and, b) in higher primates the W-cell pathway is preserved in the LGN intercalated layers, and that the full compliment of W, X, and Y pathways participate in the encoding and transmission of visual information from retina to cortex.

Provided the first report of the effects of monocular deprivation on the physiological response properties of relay cells in the LGN of a primate. Comparison of physiologically identified relay cells histologically localized to deprived vs. non-deprived LGN laminae revealed no alteration in the distribution of functional properties of any cell class despite a reduction in cell size of the deprived LGN laminae. This result disallowed previous models of deprivation induced amblyopia based on a direct competition between X and Y retinal afferents for post-synaptic targets within the main layers of the LGN. Proposed a new model of developmental amblyopia in primates that resulted from cortical changes due to reduced input from the deprived LGN laminae rather than to a selective loss of input from a particular functional cell class.

Graduate Research Fellow, Biopsychology Program (1978-1980)

Syracuse University, Department of Psychology. Doctoral Thesis: "Psychophysical Determinants of Temporal Processing in the Human Fovea." Measured foveal temporal processing characteristics using a combination of the Two-Pulse paradigm and Stiles' two color increment threshold technique. The results demonstrated that, in the temporal domain, the fovea behaves as a low-pass filter at absolute threshold independent of stimulus size. In the light adapted state, low-pass filter characteristics are observed provided stimulus size is within the limits of intensity-area reciprocity. Beyond these limits, foveal filter characteristics are band-pass and exhibit a progressively increasing low frequency attenuation (greater inhibitory effects) either as a function of increasing stimulus size or background luminance. Additionally, the results demonstrated the necessity for temporal processing models to accurately account for temporal probability summation effects.

Graduate Research Fellow, Physiological Psychology Program (1977-1978)

Syracuse University, Department of Psychology, Visual Psychophysics Laboratory. Investigated monoptic and dichoptic contributions to temporal brightness enhancement, demonstrating that the Broca-Sulzer effect originates before the combination of the individual monocular pathways at the cortical level. Also, isolated and characterized the contributions of sustained and transient mechanisms to brightness enhancement effects utilizing a unique spatio-temporal stimulus paradigm to produce and control selective transient adaptation.

Characterized brightness and darkness sensations in the human fovea using multidimensional and suprathreshold scaling techniques. Discovered and characterized asymmetries between brightness and darkness percepts in terms of sensation magnitude, flash durations producing maximal sensation, and in the minimal luminance changes necessary for brightness and darkness enhancement effects to be produced. Demonstrated that brightness and darkness sensations are generated by separate neuronal systems.

Graduate Research Associate (1976-1977)

Syracuse University, School of Engineering, Institute for Sensory Research, and Department of Psychology, Visual Psychophysics Laboratory. Investigated contextual determinants of perceived length illusions using absolute magnitude estimation. Demonstrated that when all visual cues to context are eliminated, including contextual reference cues based on the limits of the visual field, the Horizontal-Vertical Illusion does not exist. Additionally, investigated methodological determinants of the Law of Size Constancy by scaling perceived line length as a function of viewing distance. Perceived length obeys the Law of Size Constancy when viewing distance is varied within sessions, whereas, across sessions perceived length increases as an inverse function of viewing distance.

Undergraduate Research Assistant (1974-1976)

Syracuse University, Department of Psychology. Supported National Eye Institute grant research "Mechanisms of Visual Sensitivity". Investigated spatial dependence of rod-cone interactions measured on scotopically equated adapting fields using the Crawford early light and dark adaptation paradigm. Temporal profiles of size dependent rod-cone interactions during transient light adaptation were characterized. Additionally investigated spectral sensitivity of Stiles π–mechanisms to incremental and decremental stimuli, suprathreshold two-pulse interaction, adaptive independence of the Stiles π_0 mechanism, blue cone spatial and temporal integration, and perceptual correlates of on- and off- center pathways.

DECLARATION OF
William Kanemoto

I**, William Kanemoto,** declare as follows:

1. I am presently under contract with Aspen Environmental Group to provide environmental technical assistance to the California Energy Commission. Under Contract No. 700-11-027, I am serving as a Visual Resource Specialist to provide Peak Workload Support for the Energy Facility Siting Program and for the Energy Planning Program.

2. A copy of my professional qualifications and experience is attached hereto and incorporated by reference herein.

3. I helped prepare the staff testimony on **Visual Resources** for the **Palen Solar Electric Generating System Final Staff Assessment,** based on my independent analysis of the Application for Certification and supplement hereto, data from reliable documents and sources, and my professional experience and knowledge.

4. It is my professional opinion that the prepared testimony is valid and accurate with respect to the issue addressed therein.

5. I am personally familiar with the facts and conclusions related in the testimony and if called as a witness could testify competently thereto.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge and belief.

Dated: 8-2-13 Signed: [signature]

At: **Oakland, California**

William Kanemoto

Principal Investigator, Visual Analysis and Visual Simulation

Professional Experience:

Principal
William Kanemoto & Associates, Oakland, California, 1993 - Present

William Kanemoto is Principal of William Kanemoto & Associates, an environmental consulting practice specializing in visual analysis and computer visualization in the context of environmental review. He has served as principal investigator for visual analysis and simulation on a wide range of major infrastructure and development projects over the past 26 years. Mr. Kanemoto received an *Outstanding Performance Award from the California Energy Commission* for his visual analysis of numerous major power plant applications on behalf of the CEC between 2000 and 2002. He also received recognition from the *California Association of Environmental Professionals* for visual analysis, computer simulation, animation, and video production for the Stanford Sand Hill Road Projects EIR, prepared by EIP Associates and judged 'Best State-Wide EIR of 1997'

Associate Director
Environmental Simulation Laboratory,
Institute of Urban and Regional Development &
Center for Environmental Design Research
University of California, Berkeley, 1994 - 2000

Instructed graduate students in the College of Environmental Design, U.C. Berkeley, served as consultant on various major planning projects in the San Francisco Bay Area, and conducted design collaborations with counterparts at Keio University and ARK CyberUniversity in Tokyo, Japan via the internet.

Principal Investigator/Project Manager
Dames & Moore, San Francisco/Oakland, California, 1988-1992

Served as principal investigator of numerous visual analyses for major infrastructure projects throughout the U.S., in Europe, and in Asia. Gained extensive familiarity with the application of a wide range of professionally accepted visual assessment techniques in the context of CEQA, NEPA, and related regulatory requirements of the CPUC, CEC, FERC, DOT, Cal SHPO, BCDC, U.S. Forest Service, BLM, National Park Service, and other public agencies.

Project Manager
LSA Associates, Pt. Richmond, California, 1987-1988

Project manager and planner on environmental impact reports for various residential and commercial development projects in northern California.

Environmental Planner
Holton Associates, Berkeley, California, 1984-1987

Preparation of various resource and regulatory studies including EIRs, FERC Exhibit Es, Section 404 alternative analyses, riparian restoration studies, and cumulative impact methodology studies for EPRI and Sierra County, CA.

Academic Background:

M. Landscape Architecture, University of Michigan, Ann Arbor, 1982
B.A. Liberal Arts (Honors), University of California, Santa Cruz, 1973

Selected Relevant Experience

- *Visual Analysis, Rio Mesa Solar Project.* Visual analysis for CEC Preliminary Staff Assessment of solar thermal project in Riverside County.
- *Visual Analysis, California Energy Commission*. Visual analysis, expert witness testimony for environmental review of numerous major power plant applications throughout California. Conducted visual analysis for staff assessment of 6 'fast-track' thermal solar power plant applications in 2009 – 2010, and of numerous other applications since 2001.
- *Topaz Solar Project EIR.* San Luis Obispo County. Visual analysis of solar PV project in Carizzo Plain.
- *Fresno to Bakersfield High Speed Train EIR/S.* California High-Speed Rail Authority. Prepared visual analysis and 20+ simulations for the Fresno to Bakersfield High Speed Train Fresno to Bakersfield EIR/S.
- *Santa Rosa Incremental Recycled Water Program.* Visual simulations of a wide range of water treatment, storage, conveyance, and injection facilities were prepared at locations throughout Sonoma County.
- *Las Gallinas Water Storage EIR, Marin MWD.* Visual analysis and simulation.
- *Shaver Grade Pipeline Improvements*, Marin MWD. Visual simulations.
- *Tennessee Hollow Watershed Restoration EA,* Presidio National Park, GGNRA, San Francisco
- *Ventura Keys and Arundell Barranca Watershed Water Quality Improvements Video*. A video incorporating live footage and computer visualization was produced and presented in public meetings, on cable television, and distributed publicly on tape cassette.
- *Alta Infill II Wind Power Project EIR.* Visual analysis and simulation of wind project adjoining BLM lands within the Tehachapi Wind Resource Area.
- *Visual Impact Assessment Technical Reports*, Caltrans District 4. On-call visual analysis for numerous highway improvement projects throughout District 4.
- *San Onofre Nuclear Generating Station Steam Generator Replacement EIR,* CPUC
- *Diablo Canton Nuclear Generating Station Steam Generator Replacement EIR,* CPUC
- *BART to Silicon Valley EIR/S,* BART/SCVTA*.* numerous computer simulations of proposed BART Stations and associated facilities in Milpitas, downtown San Jose, and Santa Clara. Tasks included realistic simulation of then-unbuilt San Jose City Hall, from design drawings of Meier and Partners, and recently completed simulations of proposed Diridon Station parking structure, BART station, and future environs.
- *Encinal Project,* Oakland CA. Visual analysis, computer simulations, and computer-generated shadow studies for a proposed high-rise project in downtown Oakland. Study included 3D computer baseline modeling of a 20-block area of downtown Oakland.
- *Santa Clara Street-Alum Rock LRT/BRT Project,* SCVTA. Produced visual analysis and computer simulations of proposed LRT line from downtown San Jose to Capitol Avenue.
- *Highway 152/156 Interchange Project VIA*. Produced visual impact assessment technical report per Caltrans requirements, and computer simulations of a new interchange project in southern Santa Clara County for SCVTA.
- *Tasman Light Rail/Great Mall Station, Santa Clara County*. Prepared computer simulations of a proposed elevated light rail station for the Santa Clara Valley Transportation Agency.
- *Capitol Safety Barrier EIR*, Sacramento, CA. Prepared computer simulations of proposed barrier and entrance structure designs surrounding the State Capitol, to address concerns of visual compatibility with the highly sensitive historic landmark.
- *Stanford University Medical Center Improvements, Stanford Shopping Center Improvements EIR.* Computer simulations of two major projects on Stanford campus.
- *Stanford West/Sand Hill Road Projects EIR*, Stanford University. Visual analysis and extensive computer simulation of a 300+ unit apartment complex, a 680 + unit senior housing development and health center, major improvements to the Stanford Shopping Center, and construction of a major arterial roadway, for the City of Palo Alto. Computer animation and video presentation of Sand Hill Road projects were produced for presentation at public hearings and on cable TV.

DECLARATION OF
Steven Kerr

I, **Steven Kerr,** declare as follows:

1. I am presently employed by the California Energy Commission in the Environmental Office of the Siting, Transmission and Environmental Protection Division as a Planner II.

2. A copy of my professional qualifications and experience is attached hereto and incorporated by reference herein.

3. I helped prepare the staff testimony on **Alternatives** for the **Palen Solar Electric Generating System Final Staff Assessment,** based on my independent analysis of the Application for Certification and supplement hereto, data from reliable documents and sources, and my professional experience and knowledge.

4. It is my professional opinion that the prepared testimony is valid and accurate with respect to the issue addressed therein.

5. I am personally familiar with the facts and conclusions related in the testimony and if called as a witness could testify competently thereto.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge and belief.

Dated: 8/2/13 Signed: [signature]

At: Sacramento, California

Steven Kerr

Professional Experience:

California Energy Commission — Sacramento, CA
January 2012-Present — *Planner II*

- Review power plant applications and amendments for socioeconomic, land use, transportation, and visual impacts.
- Evaluate projects in accordance with CEQA, the California Energy Commission siting regulations, and federal, state and local laws, ordinances, regulations, standards (LORS).
- Participate in public workshops and hearings regarding proposals.
- Write environmental analysis documents.

Thomas P. Kerr Inc. — Sacramento, CA
August 2011-January 2012 — *Property Manager*

- Management of properties and assets throughout California and Oregon.
- Assist in the preparation of mobile home park closure impact report for Port of San Luis.
- Use various software applications to produce and review billing and financial records.
- Work with local agencies to coordinate infrastructure improvements.

Ground(ctrl) — Sacramento, CA
February 2010-August 2011 — *Director of Customer Support*

- Coordinate and provide customer support for A-list musical artist fan clubs, online stores, e-mail marketing, ticketing, aggressive online marketing, and much more.
- Resolve escalated customer support issues, credit card disputes, and Better Business Bureau cases.
- Supervise and train customer support team members and interns.

City of Sacramento — Sacramento, CA
General Services Department — *Customer Service Representative*
July 2009-February 2010

- Perform concurrently multiple customer service related duties for all City of Sacramento departments by phone/email.
- Interpret and apply City regulations and procedures as applicable to billing, fees, and collections.
- Learn and explain the organization, procedure and operation details of the City.
- Use a variety of business software applications and assess maps.

City of Sacramento — Sacramento, CA
Development Services Department — *Assistant Planner*
February 2007-July 2009

- Project manager for various residential, commercial, industrial, and office development projects.
- Assist customers with zoning, design review, preservation, environmental, subdivision code, and sign questions, both at the public counter and by phone/email.
- Provide customers with required entitlement information, fee estimates, and accept applications for proposed development projects.
- Review applications and plans for consistency with City Codes, General Plan, and applicable community plans, specific plans and planned unit development guidelines.
- Present projects at community meetings and work with neighborhood association leaders on controversial projects.
- Write staff reports and conditions of approval.
- Present projects at Zoning Administrator, Planning Commission, and City Council public hearings.
- Research development and entitlement histories of parcels.

City of Atascadero — Atascadero, CA
Community Development Department — *Planning Intern*
March 2005-June 2006

- Prepare environmental review documents.
- Review business licenses and building permits.
- Draft letters and staff reports.
- Respond to questions from the public on planning and zoning related issues.
- Access and update information in GIS and Excel

Education:

2005-2006 California State Polytechnic University, San Luis Obispo, CA
Coursework toward MS in Public Policy

2000-2005 California State Polytechnic University, San Luis Obispo, CA
Bachelor of Science in City and Regional Planning

DECLARATION OF
Shahab Khoshmashrab

I, **Shahab Khoshmashrab,** declare as follows:

1. I am presently employed by the California Energy Commission in the Engineering Office of the Siting, Transmission and Environmental Protection Division as a Senior Mechanical Engineer.

2. A copy of my professional qualifications and experience is attached hereto and incorporated by reference herein.

3. I prepared the staff testimony on **Noise and Vibration** and **Facility Design** for the **Palen Solar Electric Generating System Final Staff Assessment,** based on my independent analysis of the Application for Certification and supplement hereto, data from reliable documents and sources, and my professional experience and knowledge.

4. It is my professional opinion that the prepared testimony is valid and accurate with respect to the issue addressed therein.

5. I am personally familiar with the facts and conclusions related in the testimony and if called as a witness could testify competently thereto.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge and belief.

Dated: 8/1/2013 Signed: [signature]

At: Sacramento, California

Shahab Khoshmashrab
Senior Mechanical Engineer

Experience Summary

Eighteen years experience in the mechanical, civil, structural, and manufacturing engineering fields involving engineering and manufacturing of various mechanical components and building structures. This experience includes QA/QC, construction/licensing of electric generating power plants, analysis of noise pollution, and engineering and policy analysis of thermal power plant regulatory issues.

Education

- California State University, Sacramento-- Bachelor of Science, Mechanical Engineering
- Registered Professional Engineer (Mechanical), California
  License No. M 32883, Exp. 9/30/2014

Professional Experience

2001-Current—Senior Mechanical Engineer – Siting, Transmission, and Environmental Protection Division – California Energy Commission

- Perform analysis of generating capacity, system reliability and safety, energy efficiency, noise and vibration, jurisdictional determination, and the mechanical, civil, electrical, and structural aspects of power plants during licensing, construction, and operation.

- As the Facility Design Unit's lead, or senior, review and manage the work of technical staff (other engineers) and contractors; ensure project deadlines are met; and ensure that projects propose and implement the most energy efficient technologies to satisfy project objectives while protecting the environment;

- Independently review and evaluate Applications for Certification to ensure compliance of power plants and related facilities with applicable laws, ordinances, regulations, and standards and California Environmental Quality Act, or CEQA;

- Prepare and recommend to the Siting Committee, conditions of certification (including mitigation measures) under which power plants should be licensed, constructed and operated;

- Present oral and written expert testimonies in support of analysis at evidentiary hearings held before the Siting Committee and the public; and

- Assist the California Energy Commission in policy making related to power generation.

1998-2001—Structural Engineer – Rankin & Rankin

Engineered concrete foundations, structural steel and sheet metal of various building structures including energy related structures such as fuel islands. Performed energy analysis/calculations of such structures and produced both structural plans and detailed shop drawings using AutoCAD.

1995-1998—Manufacturing Engineer – Carpenter Advanced Technologies

Managed manufacturing projects of various mechanical components used in high tech medical and engineering equipment. Directed inspection of first articles. Wrote and implemented QA/QC procedures and occupational safety procedures. Conducted developmental research of the most advanced manufacturing machines and processes including writing of formal reports. Developed project cost analysis. Developed/improved manufacturing processes.

DECLARATION OF
Andrea Koch

I, **Andrea Koch,** declare as follows:

1. I am presently employed by the California Energy Commission in the Environmental Office of the Siting, Transmission and Environmental Protection Division as an Environmental Planner II.

2. A copy of my professional qualifications and experience is attached hereto and incorporated by reference herein.

3. I helped prepare the staff testimony on **Traffic and Transportation** for the **Palen Solar Electric Generating System Final Staff Assessment,** based on my independent analysis of the Application for Certification and supplement hereto, data from reliable documents and sources, and my professional experience and knowledge.

4. It is my professional opinion that the prepared testimony is valid and accurate with respect to the issue addressed therein.

5. I am personally familiar with the facts and conclusions related in the testimony and if called as a witness could testify competently thereto.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge and belief.

ANDREA KOCH

PROFESSIONAL EXPERIENCE

CALIFORNIA ENERGY COMMISSION, December 2009 – Present
Siting, Transmission, and Environmental Protection Division, Sacramento, California
Environmental Planner II- Perform environmental review of power plant applications.

- Review power plant applications for traffic and transportation and land use impacts.
- Write environmental analysis documents.

CITY OF SACRAMENTO, June 2007 – July 2009
Planning Department, Long-Range Planning Division, Sacramento, California
Assistant Planner- Performed long-range city planning for Sacramento.

- Coordinated review of the Draft 2030 General Plan, a comprehensive citywide land use plan.
- Prepared Ben Ali and Hagginwood neighborhood plans. Worked with City staff and community members to identify strategies for resolving neighborhood issues, such as infrastructure deficiencies.
- Reviewed 70 development applications, analyzing their consistency with City policy and providing written feedback to applicants.

COUNTY OF SANTA CRUZ, June 2005 – June 2007
Planning Department, Environmental Planning Division, Santa Cruz, California
Resource Planner II- Performed resource planning for Santa Cruz County.

- Reviewed development permit applications to ensure their consistency with regulations for creeks, wetlands, grading, geologic hazards, erosion control, and sensitive plant and animal species.
- Wrote staff reports analyzing development proposals and providing recommendations to the Environmental Planning Division Manager.
- Performed an average of 5 weekly pre-construction meetings and final inspections at project sites to ensure that development was consistent with County regulations and required mitigations.
- Regularly assisted the public with resource planning questions, both in-person and over the phone.

COUNTY OF MONTEREY, November 2004 – June 2005
Planning Department, Marina, California
Assistant Planner- Performed current planning for Monterey County.

- Reviewed development permit applications for consistency with County regulations.
- Prepared and presented staff reports for development applications. Reports provided recommendations to the Zoning Administrator.
- Assisted the public with zoning questions, both in-person and over the phone.

EDUCATION

California Polytechnic State University, San Luis Obispo, California

- Master of City and Regional Planning, Concentration in Environmental Planning, 2004

University of California, Davis

- Bachelor of Science in Wildlife, Fish, & Conservation Biology, Concentration in Conservation Biology, 2002
- Graduated with High Honors and a Department Citation

DECLARATION OF
Nicholas Lancaster

I, **Nicholas Lancaster,** declare as follows:

1. I am presently employed by the Desert Research Institute, Nevada System of Higher Education, in the Division of Earth and Ecosystem Sciences as a Research Professor.

2. A copy of my professional qualifications and experience is attached hereto and incorporated by reference herein.

3. I helped prepare the staff testimony on **Biological Resources** for the **Palen Solar Electric Generating System Final Staff Assessment,** based on my independent analysis of the Application for Certification and supplement hereto, data from reliable documents and sources, and my professional experience and knowledge.

4. It is my professional opinion that the prepared testimony is valid and accurate with respect to the issue addressed therein.

5. I am personally familiar with the facts and conclusions related in the testimony and if called as a witness could testify competently thereto.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge and belief.

Dated: 06/08/2013 Signed: ____________________

At: Reno, Nevada

NICHOLAS LANCASTER

Research Professor - Division of Earth and Ecosystem Sciences
Desert Research Institute
2215 Raggio Parkway
Reno, NV 89512
775-673-7304
Nick.Lancaster@dri.edu

Education

B.A	1971	Geography, University of Cambridge (College Exhibitioner and Scholar)
M.A.	1975	Geography, University of Cambridge
Ph.D.	1977	Geography, University of Cambridge

Positions held

2005-2008	Senior Director, Center for Arid Lands Environmental Management, Desert Research Institute
2003-2005	Program Coordinator, Earth Surface Dynamics Program, U.S. Geological Survey, Reston, Virginia
2002-present	Distinguished Research Associate, School of Geography, University of Oxford
2000	Acting Deputy Director, Division of Earth and Ecosystem Sciences, Desert Research Institute
1999-2009	Adjunct Professor, Department of Geography, University of Guelph, Ontario, Canada
1994-present	Research Professor, Quaternary Sciences Center (now Division of Earth and Ecosystem Sciences), Desert Research Institute
1991-1994	Associate Research Professor, Quaternary Sciences Center, Desert Research Institute
1989-1990	Visiting Assistant Professor, Department of Geology, Arizona State University
1986-1988	Faculty Research Associate, Department of Geology, Arizona State University
1984-1985	Visiting Faculty Research Associate, Planetary Geology Group, Department of Geology, Arizona State University
1984-1997	Visiting Lecturer, Department of Geological Sciences, University of Texas, November 1984
1983-1985	Lecturer and Senior Research Officer, Department of Environmental and Geographical Science, University of Cape Town, South Africa
1980-1982	Research Officer, Desert Ecological Research Unit, Gobabeb, Namibia
1978-1979	Assistant Lecturer, Department of Geography, University of the Witwatersrand, South Africa
1973-1978	Lecturer in Soil Science/Hydrology, Chancellor College, University of Malawi
1971-1973	NERC Research Studentship, Department of Geography, University of Cambridge

Honors and Awards

2007: Regents Researcher Award, NSHE
2002: Nominated for Researcher of the Year, UCCSN
2002: Distinguished visiting researcher, School of Geography, University of Oxford
2001: El-Baz Award for Desert Research, Quaternary Geology and Geomorphology Division, Geological Society of America
2000: Outstanding Faculty Member, University and Community College System of Nevada.
2000: Hart Fellowship, University of Sheffield
1997: Distinguished Career Award, Association of American Geographers, Geomorphology Specialty Group
1995: Nominated for Researcher of the Year, UCCSN
1994: Dandini Medal of Science, Desert Research Institute
1993: Gladys W. Cole Research Award for Geomorphology, Geological Society of America
1992: Outstanding Faculty Member, University of Nevada System

Membership in Professional Societies

Fellow: Royal Geographical Society, Geological Society of America
Member: Association of American Geographers, International Association of Sedimentologists, British Geomorphological Research Group, American Quaternary Association, Sigma Xi, American Association for the Advancement of Science, International Society for Aeolian Research

Professional Service

Editorial Positions

2011 Guest Editor (with Xiaoping Yang and David Thomas) *Special Issue of Quaternary Science Reviews* – Spatial and temporal complexity in Quaternary desert datasets: implications for interpreting past dryland dynamics and understanding potential future changes
2010-present Guest Editor (with Joh Henschel) *Special Issue of Journal of Arid Environments – Namib Desert*
2009-present Co-Editor (with Andreas Baas and Doug Sherman), *Treatise on Geomorphology, Volume 11, Aeolian Geomorphology*, Elsevier.
1992-present Editorial Board member, *Geomorphology*
1998-present Editorial Board member, *Earth Surface Processes and Landforms*
1999-present Editorial Board member, *Sedimentology*
2001-present Editorial Board member, *Quaternary Research*
2006-2007 Guest Editor, *Journal of Geophysical Research, Earth Surface,* Special section on aeolian processes
1996, 2004,
2006-2008 Guest Editor, *Geomorphology,* Special Volumes on Aeolian Processes from ICAR conferences
2000 Guest Editor, *Quaternary International,* Special volume from IGCP 413 Workshop: Linkages between fluvial, lacustrine and aeolian systems, Desert Studies Center, Zzyzx, California
1996 Guest Editor, *Earth Surface Processes and Landforms,* Special Issue on Aeolian Processes

1991	Guest Editor (with K. Pye) Aeolian Sediments Ancient and Modern: International Association of Sedimentologists, Special Paper 16.

Review Panels and Working Groups

2011	Scientific Advisory Panel Member California Desert Renewable Energy Conservation Plan
2011	AAAS Research Competitiveness Program Review Panel for King Abdulaziz City for Science and Technology.
2011	Member Mars Science Laboratory Participating Scientist review panel
2007-present	Leader, INQUA Project 0704, Sand seas and dune fields of the world: a digital Quaternary atlas
2006-2009	International Association of Geomorphologists Working Group on the Geomorphic Implications of Global Environmental Change
2006	DRI representative to International Arid Lands Consortium (IALC) Research and Demonstration Awards Committee (RADAC)
2005-present	Member, Academic Committee, Key Laboratory of Desert and Desertification, Cold and Arid Regions Research Institute, Chinese Academy of Sciences
2005-2008	National Park Service Working Group on monitoring of geologic resources in national parks
2004	Panel Member, Earth System History Program, National Science Foundation
2004-2011	Member and sometime Vice-Chair, National Academy of Sciences, U.S. National Committee for International Union for Quaternary Research (INQUA)
2003	Secretary General, INQUA Commission for Terrestrial Processes, Environments and Deposits
1998	Member – Advisory Board, International Conference on Aeolian Research
2002-2008	International Union of Geological Sciences (IGCP) — member, Project 500: Dryland Changes, Past, Present, and Future
1999-2002	IGCP Project 413 — member, Understanding Future Dryland Changes from Past Dynamics
1993-1998	IGCP Project 349 — Member and sometime U.S. Coordinator, Desert Margins and Paleomonsoons
1986-1992	IGCP Project 252 — Member, Past and Future Evolution of Deserts
1983-1985	IGCP Project 184 — Member, Palaeohydrology of the Low Latitude Deserts

Conferences and Workshops Organized

2010	2nd Planetary Dunes Workshop, Alamosa, CO, co-organizer
2009	Titan Dunes workshop, DRI, SNSC
2009	Dunes Atlas Workshop, School of Geography, Oxford University
2007	1st Planetary Dunes Workshop, Alamogordo, NM, co-organizer
2001-2003	XVI INQUA Conference, Reno.
2000	IGCP 413, Linkages between Fluvial, Lacustrine and Aeolian systems, Workshop at Desert Studies Center, Zzyzx, California, October 2000
1994	Workshop on the Response of Eolian Processes to Global Change, Desert Studies Center, Zzyzx, California, March 1994 (ICAR III)

Session Chairs

2010	Co-organizer: Symposium - Dust in the Earth System, AAAS Annual Meeting, San Diego
2009	Co-chair: Geomorphology session at GSA, Portland
2009	Co-organizer: Symposium - Origin and Evolution of Deserts, AAAS Annual Meeting, Chicago
2007	Convenor, Symposium on Quaternary climate change in deserts, INQUA, Cairns, Australia.
2002	Convenor, Topical Session T105, Response of Dryland Geomorphic Systems to Climate Change and Variability, Geological Society of America
1997	Convenor, Theme Session, Arid Lands Geomorphology, Geological Society of America
1993	Chair, Geological Society of America, Cordilleran and Rocky Mountain Sections Meeting, Reno
1991	Co-Advocate and Session Chair (with D.F. Ritter), Theme Session 5: Global Warming and Geologic Evidence of Aridification during Late Quaternary Time, Geological Society of America Annual Meeting
1990	Co-Convenor (with K. Pye), Symposium on Aeolian Sediments and Processes, International Sedimentological Congress, Nottingham, U.K.

Positions in Professional Societies

2005-2010	Founding President, International Society for Aeolian Research (ISAR)
1992-1993	Chair, SEPM Aeolian Sediments and Processes Research Group
1985	Secretary, Southern African Society for Quaternary Research
1982-1985	Executive Committee Member, Southern African Society for Quaternary Research

Invited Participation in Meetings and Working Groups

2010	Invited presentation (with Stephen Scheidt), AGU Fall Meeting Session
2010	Invited keynote speaker, Global Sand Seas: past, present, future, Royal Geographical Society, London, UK.
2010	Presidential Address, ICAR VII, Argentina
2002	Invited speaker, GSA Annual Meeting, Pardee Symposium, *There and Back Again: Terrestrial Approaches to Extraterrestrial Problems*
1997	Invited observer, *Management Scale Ecosystem Research Workshop,* DoD/ DOE/EPA Strategic Environmental Research and Development Program, Warrenton, Virginia
1996	Invited keynote speaker, International Conference on Desert Development on the Arab Gulf Countries, Kuwait, *Understanding the dynamics of aeolian sand transport systems - an overview of recent progress*
1991	Invited speaker, Los Angeles County Museum of Natural History Symposium, *Southern California Climate, Trends and extremes of the past 2000 years*
1991	Invited speaker, GSA Annual Meeting, Quaternary Geology and Geomorphology Division Symposium: *Quaternary climatic change in arid and semiarid western North America: evidence from the Great Basin, Desert Southwest, and Great Plains*

1990	Invited speaker, NATO Advanced Research Workshop, *Sand, Dust and Soil in their Relation to Aeolian and Littoral Processes,* Sandbjerg, Denmark
1989	Invited speaker, 28th International Geological Congress, Washington D.C., Symposium on Aeolian Sediments
1989	Invited speaker and symposium participant, American Association for the Advancement of Science, Annual Meeting, NASA Ames Research Center, Aeolian Consortium, 1986-1991
1987	Invited speaker, GSA Annual Meeting, History of Geology Division Symposium: *History of Studies of Arid Lands, Ancient and Modern*
1987	Panel member, SEPM Bedforms and Bedding Structures Research Symposium, S.E.P.M. Mid Year Meeting, Austin, Texas
1986	Invited Speaker and Panel Member, 17th Binghamton Symposium in Geomorphology, *Aeolian Geomorphology*
1985	Invited speaker, Geological Society of America Penrose Conference, Geomorphic and Stratigraphic Indicators of Climatic Change in Arid and Semiarid Environments, Lake Havasu City, Arizona

Field Trips and Short Courses

1999	Leader, Cenozoic Landforms and Deposits of the Western Kalahari and Central Namib Desert, Namibia, *XV INQUA Congress Field Excursion B9*
1996	Co-leader (with K. Adams and others), Friends of the Pleistocene Pacific Cell, Fall field trip to Lake Lahontan Basin
1994	Co-leader (with S.G. Wells and others), G.S.A. Cordilleran Section field trip, Quaternary Stratigraphy and Dating Methods: Understanding Geologic Processes and Landscape Evolution in Southern California
1990	Co-leader (with O.K. Davis and others), G.S.A. Cordilleran Section field trip, Quaternary and Environmental Geology of the Northeastern Gulf of California
1988:	Convenor (with R. Greeley), Dynamics of aeolian processes, Graduate College Faculty Research Conference, Arizona State University
1988	Contributor, Short Course on Aeolian Processes for Kuwait Institute of Scientific Research, Arizona State University
1983	Co-Leader, International Symposium on Late Cenozoic Palaeoclimates of the Southern Hemisphere, Swaziland; Post symposium field excursion to Kalahari and Namib Deserts, September 1983
1983	Co-organizer (with J.C. Vogel and J. Deacon), Workshop on the Evidence for Late Quaternary Climatic change in Southern Africa, Johannesburg

Guest Lectures and Seminars

2008	Texas A&M University, Department of Geography
2004	Rutgers University, Department of Geological Sciences, Quaternary Studies Program
2004	University of Oxford, Department of Geography
2003	University of Pittsburgh, Department of Geological Sciences
2000, 2004	University of Sheffield, Department of Geography
1999	University of California, Santa Barbara, Department of Geography
1999	University of Nebraska, Lincoln, Department of Geosciences
1998	Trent University, Ontario, Canada, Department of Geography

1993, 1996, 1998	University of Guelph, Ontario, Canada, Department of Geography
1993	University of Nevada, Las Vegas, Department of Geology
1991	University of Nevada, Reno, Department of Geography
1989	University of California, Los Angeles, Department of Geography
1989	University of Southern California, Department of Geography
1989, 1993	Arizona State University, Department of Geography
1988	Northern Arizona University, Department of Geology
1987, 1990	University of Arizona, Department of Geosciences
1985	University of California, Berkeley, Department of Geography
1984, 1988	University of Texas at Austin, Department of Geological Sciences

Organizing Committees

2007, 2010	Planetary Dunes Workshops
2003	Secretary General INQUA Congress, Reno
2000	Hot Topics Chair, Geological Society of America, Annual Meeting, Reno
1998	DRI/Army Research Office: New Research Directions in Desert Surfacial Processes and Landscape Dynamics on Military Lands, Desert Studies Center, Zzyzx, California
1997	International Symposium: Changing Water Regimes in Drylands, Desert Research Institute
1990	IGCP Project 252 Past and Future Evolution of Deserts Annual Meeting, Tucson, Arizona
1983	International Symposium on Late Cenozoic Palaeoclimates of the Southern Hemisphere, Swaziland

Manuscript Reviews

Science, Sedimentology, Journal of the Geological Society of London, Journal of Sedimentary Research, Journal of Geology, Geology, Geological Society of America Bulletin, Journal of Geophysical Research, Earth Surface Processes and Landforms, Geomorphology, Geography, Catena, South African Geographical Journal, Palaeoecology of Africa, Association of American Geographers Annals, University of Arizona Press, Canadian Journal of Earth Sciences, Quaternary Research, Remote Sensing of Environment (and many others)

Grant Reviews

Council for Scientific and Industrial Research (Foundation for Research Development, South Africa)
National Geographic Society
United States Geological Survey
National Science Foundation
NASA
Natural Environment Research Council (UK)
Australian Research Council
Norwegian Research Council
Israel-USA Bi-National Science Foundation

Desert Research Institute Committees

2008 -2010	Institute Promotions Committee (chair 2009)
2006	Reallocation Committee (Facilities Working Group)
2006	DEES Promotions Committee (chair)
2005-2007	Research Affairs Committee
2002	Search Committee, CIASTA Director
1999-2000	Co-chair, Search Committee for Division of Earth and Ecosystem Sciences Director
1999	Division of Earth and Ecosystems Science Council
1999-2001	Institute Promotions Committee
1998	Organizing Committee, New Research Directions in Desert Surface Processes in and Landscape Dynamics on Military Lands, Desert Studies Center, Zzyzx, April 1998
1998-2001	Chair, Organizing Committee, Symposium on Changing Water Regimes in Drylands
1997, 2000, 2005-present	J.O. Davis Scholarship Selection Committee
1996-1997	Chair, Search committee for fluvial geomorphologist, QSC
1996-1997	Promotions Committees, DRI and QSC
1995	Search Committee for EEEC Center Director
1995-1998	Status of Women Committee
1995-1996	Strategic Planning Group
1995- 2000	Dandini Medal Committee (chair, 1999)
1995	Computer Committee
1994-1996	Northern Nevada Science Center Steering Committee
1994 -1998	Chair, Colin Warden Memorial Endowment Committee

NSHE Committees

2002	Member, Nevada Space Grant Consortium
1999	UCCSN Teaching Award Committee
1993-1996	Nevada Consortium on Geology, Geophysics and Geochronology
1996-1998	Nevada EPSCoR Proposal Development Panel Member.

UNR Committees

1999-2003	Curriculum Committee, Department of Geological Sciences

Grants and Contracts

Current

2011-present	Co-I NASA MFRP – Dune trends and atmospheric modeling
2009-present	Co-PI, GBUAPCD – Keeler Dunes history and dynamics
2008-present	Co-PI Nevada NSF EPSCoR – Nevada Infrastructure for Climate Change Science, Education, and Outreach -National Science Foundation Cooperative Agreement EPS-0814372
2007-present	PI, INQUA Project 0704, Sand seas and dune fields of the world: a digital Quaternary atlas

Past

2010-2011	Co-PI SLOAPCD – Oceano Dunes dust emissions
2010-2011	PI - British Petroleum – Pipelines and dune mobility
2009-2010	PI- Otis Bay – Ash Meadows restoration
2007-2011	Co-PI NASA ESPCoR Planetary Surfaces
2008-2010	Co-I, Israel Bi-national Science Foundation – Negev Dunes (with Haim Tsoar and Dan Muhs)
2006-2010	Principal Investigator, Visualization of sand dune and sand sea development, DOD/STTC.
2006-2008	Principal Investigator, Fringe toed lizard habitat study, Coachella Valley, CA, USGS Denver
2003-2008	Co-Principal Investigator (with Michael Ramsey, University of Pittsburgh) Eolian processes in arid regions, NASA Earth Sciences Division.
2003-2006	Co-PI, (with Dave Loope and Clint Rowe), Collaborative Research: Paleometeorological records from sand dunes and eolian sandstones, National Science Foundation
2003-2006	Co-Principal Investigator, Airflow and Sediment Transport in Complex Terrains on Mars: A Shear Stress Partitioning Approach, NASA Mars Fundamental Research Program
2002-2006	Principal Investigator, ACS/PRF: Internal Sedimentary structure of desert dunes
2002-2003	Principal Investigator, Nevada Space Grant, Sand transport pathways
2001-2003	Co-Principal Investigator, National Science Foundation, Aeolian Processes in the McMurdo Dry Valleys, Antarctica
2001-2002	Principal Investigator, US Geological Survey, Sand transport at Owens Lake,
2001	Co-PI (with R. Webb, USGS), Long-term sand supply to Coachella Valley fringe-toed lizard (*uma inornata*) habitat in the northern Coachella Valley, California
2000-2001	Principal Investigator, Bureau of Land Management, Dune dynamics in the Christmas Valley, Oregon
2000-2002	Co-PI (with Jack Gillies): USDA, Influence of dryland vegetation on sediment transport by wind
1999-2000	Principal Investigator, USGS, Mojave Desert wind erosion study,
1999	Principal Investigator, NOAA, Climate change research - Analysis of data from Geomet stations

1999-2002	Co-PI (with Jack Gillies), National Science Foundation, Fundamental studies of the dust emission process
1999-2000	PI: Twentynine Palms IT/LP Science Advisory Team, Tierra Data Systems
1998-2001	Principal Investigator, National Science Foundation, Relations between sand transport rates and natural desert vegetation cover
1998–2001	Principal Investigator, Great Basin Unified Air Pollution Control District, Studies of managed vegetation as a control for dust emissions from Owens Lake, California (includes 4 separate contracts)
1997-1998	Principal Investigator, USGS, Wind erosion studies
1996-1997	Principal Investigator, NASA, Orbital radar studies of the McMurdo Dry Valleys, Antarctica
1995-1997	Principal Investigator, Great Basin Unified Air Pollution Control District, Studies of effect of natural vegetation on sand transport
1993-1996	Principal Investigator, Department of Energy, Great Basin Paleoenvironmental Studies, Geomorphology
1993-1996	Principal Investigator, Desert Research Institute, Internal Project Assignment, SIR-C Radar Data Analysis
1993	Principal Investigator, Nature Conservancy, Coachella Valley Preserves Project
1993-1994	Luminescence Dating Laboratory Equipment Grant, E.L. Cord Foundation
1993-1994	Aeolian Processes at Owens Lake, CA., Great Basin Unified Air Pollution Control District
1992-1999	Principal Investigator, Soil Remediation studies and wind erosion potential, Nevada Test Site, Department of Energy (multiple contracts)
1992-1996	Princiopql Investigator, E.L. Cord Foundation, Quaternary Geochronology Laboratory equipment
1992-1994	Principal Investigator, National Science Foundation, Earth Sciences Division, Global Change Program, Response of eolian geomorphic systems to climatic change
1992-1994	Principal Investigator, Evolution of the Namib Sand Sea, National Geographic Society
1992-1993	Co-Principal Investigator, Bioanthropology Foundation, Remote Sensing Studies In Egypt
1992-1993	Principal Investigator, Desert Research Institute, Internal Project Assignment, Stratigraphic studies of Lake Lahontan shoreline deposits
1991-1992	Principal Investigator, American Water Development: Potential effects of groundwater abstraction on Great Sand Dunes National Monument
1991	National Research Council, Travel Grant for INQUA Meeting, Beijing, China, August 1991
1990-1994	Project Coordinator, NATO Cooperative Research Program: Thermoluminescence dating of aeolian deposits in the Mojave Desert (with Ann Wintle and Helen Rendell, U.K.)
1990-1992	Principal Investigator, Development of Kelso Dunes, Mojave Desert, California, National Geographic Society
1989-1991	Principal Investigator, Formation of super bounding surfaces in modern sand seas, National Science Foundation, Earth Sciences Division
1989-1998	Associate, Earth Observing System Radar Facility Instrument Team (with G.G. Schaber and others)
1989-1990	Principal Investigator, Investigator Incentive Award, Arizona State University

1988-1989	Principal Investigator, Research Incentive Award, Arizona State University
1988-1997	Co-Investigator (with R. Greeley and others) NASA Shuttle Imaging Radar (SIR-C) Experiment
1987-1991	Co-Investigator (with R. Greeley), Martian Aeolian Processes, NASA Planetary Geology Program
1987	Co-Investigator, (with G. Kocurek) Reservoir characterization of aeolian deposits Unocal
1984-1985	Principal Investigator, Aeolian and dune processes in the Namib Sand Sea. C.S.I.R. Foundation for Research Development and University of Cape Town Research Committee
1984-1985	Principal Investigator, Dynamics of deflation hollows at Elands Bay. University of Cape Town Research Committee
1983	Principal Investigator, Dune systems in the southwestern Kalahari: Harry Openheimer Institute for African Studies, University of Cape Town
1983-1986	Principal Investigator, Late Quaternary Environments in southern Africa. C.S.I.R. Atmosphere and Climate Programme
1979	Principal Investigator, Fixed Dune Systems in the Kalahari. Senate Research Grant, University of the Witwatersrand
1974-1978	Principal Investigator, Lake Chilwa Quaternary History: University of Malawi Research and Publications Committee
1972-1973	Ph.D. fieldwork in Botswana: Royal Geographical Society, Royal Society, University of Cambridge (Smuts Memorial Fund, Philip Lake Fund)

DECLARATION OF
Geoff Lesh, PE

I, **Geoff Lesh,** declare as follows:

1. I am presently employed by the California Energy Commission in the Engineering Office of the Siting, Transmission and Environmental Protection Division as a Mechanical Engineer.

2. A copy of my professional qualifications and experience is attached hereto and incorporated by reference herein.

3. I helped prepare the staff testimony on **Traffic and Transportation** for the **Palen Solar Electric Generating System Final Staff Assessment,** based on my independent analysis of the Application for Certification and supplement hereto, data from reliable documents and sources, and my professional experience and knowledge.

4. It is my professional opinion that the prepared testimony is valid and accurate with respect to the issue addressed therein.

5. I am personally familiar with the facts and conclusions related in the testimony and if called as a witness could testify competently thereto.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge and belief.

Geoffrey Lesh, PE

WORK HISTORY

California Energy Commission   Mechanical Engineer   2002 - Current

- Analyze siting permit applications for gas-fired and solar-thermal power plants in the technical areas of hazardous materials management, fire safety, security, and worker safety plans
- Provide written and oral expert witness testimony at commission hearings on power plant fire protection plans, risk assessments, and adequacy of local fire departments
- Recommend mitigations as needed
- Inspect power plants during construction and operational phases
- Investigate accident, fire, and hazardous materials incidents at power plants

Self-Employed   Independent Investor   2000 - 2002

- Wrote market analysis computer software

Read-Rite Corp   Wafer Engineering Manager   1994 - 2000

- Designed and developed wafer manufacturing processes for computer data storage systems. Managed team of engineers and technicians responsible for developing wet and dry chemical processes for manufacturing, including process and safety documentation
- Managed process and equipment selection for manufacturing processes
- Processes included vacuum processed metals and ceramics, grinding-polishing, plating, etching, encapsulation, process troubleshooting, and SPC reporting

Dastek Corp   (Komag Joint Venture Start-up) Wafer Engineering Manager   1992 - 1994

- Developed wafer processes for new-technology recording head for hard disk drives
- Managed team of engineers and technicians
- This position included start-up of wafer fab, including line layout, purchase, installation, and startup of new process equipment, etc.

Komag, Inc   Alloy Development Manager   1989 - 1992

- Developed new vacuum-deposited recording alloys
- Responsible for planning and carrying-out tests, designing experiments, analyzing results, managing test lab conducting materials characterizations
- Extensive process modeling, experiment design and data analysis

Verbatim Corp (Kodak)   Process Development Manager   1983 – 1989

- Mechanical/materials engineering for computer disk manufacturing, including product, process, and equipment including metal-ceramic-plastic processes for optical disk development
- Production processes included metal plating, metal evaporation, reactive sputtering, laser-based photolithography, injection molding
- Steering Committee Member, Center for Magnetic Recording Research, UC San Diego
- Steering Committee Member, Institute for Information Storage Technology, Santa Clara University

IBM Corp   Mechanical/Process Engineer   1977 - 1983

- Product development for photocopiers, semiconductors, and computer data tape-storage systems

EDUCATION

Stanford University, Master of Science Degree	Materials Science and Engineering
UC-Berkeley, Bachelor of Science Degree (Double Major)	Mechanical Engineering, Materials Science and Engineering
University of Santa Clara, Graduate Certificate	Magnetic Recording Engineering

PROFESSIONAL LICENSES and CERTIFICATIONS

Registered Professional Engineer, California (PE)	Mechanical #M32576 Metallurgical #MT1940
Certified Safety Professional (CSP)	Board of Certified Safety Professionals
Certified Fire Protection Specialist (CFPS)	Certified Fire Protection Specialist Board (NFPA)
Certified Fire and Explosion Investigator (CFEI)	Board of National Association of Fire Investigators

OSHA 40-hr HAZWOPER Hazardous Materials Incident Training

PATENTS

Method of Preparing Thermo-Magneto-Optic Recording Elements, US Patent# 4,892,634, (assigned to Eastman Kodak Co.)

DECLARATION OF
Laiping Ng

I, **Laiping Ng,** declare as follows:

1. I am presently employed by the California Energy Commission in the Engineering Office of the Siting, Transmission and Environmental Protection Division as an Associate Electrical Engineer.

2. A copy of my professional qualifications and experience is attached hereto and incorporated by reference herein.

3. I helped prepare the staff testimony on **Transmission System Engineering** for the **Palen Solar Electric Generating System Final Staff Assessment,** based on my independent analysis of the Application for Certification and supplement hereto, data from reliable documents and sources, and my professional experience and knowledge.

4. It is my professional opinion that the prepared testimony is valid and accurate with respect to the issue addressed therein.

5. I am personally familiar with the facts and conclusions related in the testimony and if called as a witness could testify competently thereto.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge and belief.

Dated: 8/2/2013 Signed: Laiping Ng

At: Sacramento, California

Laiping Ng
Associate Electrical Engineer

Education:

Master of Science: Electrical Engineering - Power
California State University, Sacramento

Bachelor of Science: Electrical Engineering - Power
California State University, Sacramento

Power Certificate – EPRI

Experience:

April 1999 – Present:

- Review and evaluate electrical transmission system sections of the application to ensure that the transmission engineering aspects of the power plant, switchyards, substations, and the related facilities comply with applicable laws, ordinances, regulations, and standards (LORS).

- Prepare written analysis, which address the issues of the adequacy of proposed projects to meet applicable LORS.

- Perform load flow studies and fault analysis.

- Coordinate with CAISO, WSCC and other regulatory agencies and coordinate with utilities companies in the review and evaluation of the power plant siting process.

May 1991 – April 1999:

- Prepared engineering bid specifications for recommended lighting and HVAC projects. Evaluated contractor bids and recommended contractors to customers. Reviewed RFPs and RFQs. Evaluated, selected, and managed engineering consultants. Administrated and coordinated contracts.

- Designed electrical systems for indoor and outdoor lighting and lighting controls. Assisted in design cooling systems and controls for school buildings and office buildings. Reviewed and checked electrical lighting designs and drawings. Analyzed designs and made recommendations for effective actions.

- Performed facility energy audits and field surveys on schools, offices, hospitals and county jail facilities to identify energy efficiency improvements and cost estimate with respect to lighting and HVAC systems. Inspected lighting and HVAC system equipment installation.

- Worked with regulatory agencies to conduct day-to-day basis works such as participated in Nonresidential Energy Efficiency Standards development teams. Prepared and updated Standards concentrating on interior building illumination and indoor and outdoor flood lighting.

DECLARATION OF
Obed Odoemelam, Ph.D.

I, **Obed Odoemelam,** declare as follows:

1. I am presently employed by the California Energy Commission in the Engineering Office of the Siting, Transmission and Environmental Protection Division as a Staff Toxicologist.

2. A copy of my professional qualifications and experience is attached hereto and incorporated by reference herein.

3. I prepared the staff testimony on **Transmission Line Safety and Nuisance** for the **Palen Solar Electric Generating System Final Staff Assessment,** based on my independent analysis of the Application for Certification and supplement hereto, data from reliable documents and sources, and my professional experience and knowledge.

4. It is my professional opinion that the prepared testimony is valid and accurate with respect to the issue addressed therein.

5. I am personally familiar with the facts and conclusions related in the testimony and if called as a witness could testify competently thereto.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge and belief.

RESUME

DR. OBED ODOEMELAM

EDUCATION:

1979-1981 University of California, Davis, California. Ph.D., Ecotoxicology

1976-1978 University of Wisconsin, Eau Claire, Wisconsin. M.S., Biology.

1972-1976 University of Wisconsin, Eau Claire, Wisconsin. B.S., Biology

EXPERIENCE:

1989
The Present: California Energy Commission. Staff Toxicologist.

Responsible for the technical oversight of staffs from all Divisions in the Commission as well as outside consultants or University researchers who manage or conduct multi-disciplinary research in support of Commission programs. Research is in the following program areas: Energy conservation-related indoor pollution, power plant-related outdoor pollution, power plant-related waste management, alternative fuels-related health effects, waste water treatment, and the health effects of electromagnetic fields. Serve as scientific adviser to Commissioners and Commission staff on issues related to energy conservation. Serve on statewide advisory panels on issues related to multiple chemical sensitivity, ventilation standards, electromagnetic field regulation, health risk assessment, and outdoor pollution control technology. Testify as an expert witness at Commission hearings and before the California legislature on health issues related to energy development and conservation. Review research proposals and findings for policy implications, interact with federal and state agencies and industry on the establishment of exposure limits for environmental pollutants, and prepare reports for publication.

1985-1989 California Energy Commission.

Responsible for assessing the potential impacts of criteria and noncriteria pollutants and hazardous wastes associated with the construction, operation and decommissioning of specific power plant projects. Testified before the Commission in the power plant certification process, and interacted with federal and state agencies on the establishment of environmental limits for air and water pollutants.

1983-1985 California Department of Food and Agriculture.

Environmental Health Specialist.

Evaluated pesticide registration data regarding the health and environmental effects of agricultural chemicals. Prepared reports for public information in connection with the eradication of specific agricultural pests in California.

DECLARATION OF
Christine Stora

I, **Christine Stora,** declare as follows:

1. I am presently employed by the California Energy Commission in the Compliance Office of the Siting, Transmission and Environmental Protection Division as a Project Manager.

2. A copy of my professional qualifications and experience is attached hereto and incorporated by reference herein.

3. I prepared the staff testimony on the **Executive Summary, Introduction** and **Project Description** for the **Palen Solar Electric Generating System Final Staff Assessment,** based on my independent analysis of the Application for Certification and supplement hereto, data from reliable documents and sources, and my professional experience and knowledge.

4. It is my professional opinion that the prepared testimony is valid and accurate with respect to the issue addressed therein.

5. I am personally familiar with the facts and conclusions related in the testimony and if called as a witness could testify competently thereto.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge and belief.

Dated: 8/6/13 Signed: Christine Stora

At: Sacramento, California

CHRISTINE R. STORA

EXPERIENCE SUMMARY

Over nine years of project and staff management experience related to the development of energy projects in North America and other international locations. Technical focus on NEPA, and CEQA compliance, planning, permitting, and compliance monitoring.

PROFESSIONAL EXPERIENCE AND EDUCATION

CALIFORNIA ENERGY COMMISSION COMPLIANCE PROJECT MANAGER 06/2010 to Present

Manages power plant compliance for licensed power plants in California including solar, geothermal, and natural gas. Duties include oversight of power plant construction and ensuring that the conditions of certification are being met throughout construction, operation, and decommissioning of various power plants in California. Reviews petitions to amend existing licenses and gives recommendations to the Commission for approval or denial of requests. Coordinate with Commission technical staff, Certified Building Officers, other regulatory agencies, developers, contractors, and the public to ensure power projects are in compliance with all applicable conditions of certification and LORS. Working knowledge of CEQA, NEPA, and the Warren-Alquist Act.

Construction Compliance Project Manager for the following projects:

- Calpine's Los Esteros 2 Power Plant conversion of the simple-cycle power plant (Los Esteros I) to a combined-cycle with a total output of 320 MW located in north San Jose CA.
- GenOn's Marsh Landing Generating Station 760 MW simple-cycle power plant located in Antioch CA.
- Northern California Power Authority's Lodi Energy Center 255 MW combined-cycle power plant located in Lodi CA.
- Turlock Irrigation District's Almond 2 Power Plant 174 MW simple-cycle peaker located in Modesto CA.
- Calpine's Sutter Energy Center Grimes Pipeline, a 2.8 mile natural gas pipeline.

Amendment Project Manager:
Responsible for all Commission Amendments from 06/2010 to 4/2011. Duties included developing the Amendment Procedures Guidance Document for Compliance Project Managers at the Commission. Coordinate with technical staff, project owners and make recommendations to the Commission regarding changes.
Amendment Highlights:

- CE Obsidian Energy, LLC, Black Rock 1, 2, and 3 Geothermal Power Project amendment to increase generating capacity to 215 MW as a multi-flash, single-generator facility.

- Calpine's Sutter Energy Center (540 MW) amendment to install the 2.8 mile, 6 inch, Grimes natural gas pipeline.
- Turlock Irrigation District's Walnut Energy Center (250 MW) amendment to change annual water usage.
- Sacramento Municipal Utility District's (SMUD's) Consumnes Power Project (500 MW) amendment to inject digester gas from the Sacramento Regional Wastewater Treatment Plant into the natural gas supply line serving the CPP.

Operational Compliance Project Manager on various projects located throughout the state of California.

URS CORPORATION RENEWABLE ENERGY PROJECT AND STAFF MANAGER 11/2003 to 5/2010
Managed the Renewable Energy Group in the URS Sacramento office consisting of: Environmental Scientists, Real Estate Specialists, Marketing Staff and Biologists. As a Project Manager, I provided environmental planning services for international renewable energy clients through sitting, permitting, construction, and post construction, environmental monitoring and compliance. I coordinated multiple disciplines for NEPA and CEQA compliance documents (EISs/EIRs) and other environmental reports related to renewable energy development. I coordinated field surveys as the lead field technician (surveys included avian mortality studies for wind energy developments, wetland delineations, burrowing owl surveys, meteorological siting investigations, geotechnical investigations, and other technical disciplines). I also contributed to marketing and research efforts for the URS renewable energy marketing sector including attending conferences such as the annual Wind Power Conference held by the American Wind Energy Association (AWEA).

Professional awards and certifications include:

- URS Team Award for a Wind Energy Environmental Planning for a team I managed (February 2010)
- URS Monthly Outstanding Achievement Award for Marketing Efforts in the Renewable Energy Sector (December 2008)
- Individual Outstanding Achievement Award in Project Management (2007)
- URS Project Manager Certification (November 2007)

Assignment Highlights

Deputy Project Manager, Searchlight Wind Project, Searchlight, NV, Bureau of Land Management. Duke's Searchlight Wind Project is a 370 MW project consisting of up to 161 wind turbine generators. Provided wind energy planning services including the development of the Plan of Development, Environmental Assessment, and the EIS for the Searchlight Wind Power Project. Managed budget, schedule and technical staff in several URS offices for this effort.

Deputy Project Manager, Sacramento Municipal Utility District (SMUD) Solano Wind Project. November 2003 to March 2010. Responsible for overseeing budgets and schedule for all task orders. Monitored subcontractors and technical staff in a verity of efforts ranging from EIR preparation, biological field surveys, meteorological investigations, land acquisitions and other program activities. Proposal Manager for multiple efforts for this client. Developed program management plans and tracked tasks in MS Project. Managed task orders and staff. Contributed to strategic planning with client. Provided technical guidance and oversight to renewable energy technical staff.

Project Manager, Benicia Wind Project, Benicia CA, Silicon Valley Power (SVP). As a municipal utility SVP will be the lead agency for the EIR and other environmental documentation required for this 40 MW wind power project. Responsible for the direction of planning, environmental assessment, and consulting services provided to the client. These services include reviewing the Solano County General Plan and EIR's for surrounding projects in preparation of developing this project, assisting with the procurement, permitting, and installation of meteorological equipment, and contract negotiations.

Wind Contract Review Services, Gargau Wind Project, Rio de Janeiro, Brazil, for WestLB, Engineering Fatal Flaw Analysis. Assisted in engineering fatal flaw analysis. Documents under review included contractual agreements, the power purchase agreement, supply documents, balance of plant documents, and others. Provided project management support, including budget and schedule management for this project.

Project Management Assistance, Airtricity Asset Due Dilligance, USA and Canada, Confidential Client. Provided Project Management Assistance for an international technical team to assess the value and status of Airticity's operations for purchase by a private investing firm. At the time of the acquisition Airtricity was currently operating wind farms with around 210 MW installed capacity with an additional 880 MW to be operational by the end of 2008. Other Airtricity projects across US and Canada totaled more than 5,000 MW and were in an early development stage at the time of this project.

EDUCATION AND HONORS

Bachelor of Science Degree in Environmental Science from Humboldt State University (2003).

Academic honors include Cum Laude Honors Humboldt State University (2003) and Fall Presidential Scholar Humboldt State University (2001).

DECLARATION OF
Marylou Taylor, P.E.

I, **Marylou Taylor,** declare as follows:

1. I am presently employed by the California Energy Commission in the Engineering Office of the Siting, Transmission and Environmental Protection Division as an Associate Civil Engineer.

2. A copy of my professional qualifications and experience is attached hereto and incorporated by reference herein.

3. I prepared the staff testimony on **Soil and Water Resources** for the **Palen Solar Electric Generating System Final Staff Assessment,** based on my independent analysis of the Application for Certification and supplement hereto, data from reliable documents and sources, and my professional experience and knowledge.

4. It is my professional opinion that the prepared testimony is valid and accurate with respect to the issue addressed therein.

5. I am personally familiar with the facts and conclusions related in the testimony and if called as a witness could testify competently thereto.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge and belief.

Dated: 8-1-2013 Signed: Marylou Taylor

At: Sacramento, California

MARYLOU P. TAYLOR, PE

REGISTRATIONS/LICENCES:

California Professional Engineer License # C64353

EDUCATION:

B.S. Civil Engineering
University of California, Davis

PROFESSIONAL HISTORY:

Associate Civil Engineer 2010 to Present
California Energy Commission, Sacramento, CA
Duties within the GeoSciences Unit of the Engineering Office in the Siting, Transmission, and Environmental Protection Division include review and evaluation of applications for certification of thermal power plants within the state of California. The focus of the work is on sensitive project sites that may have issues involving groundwater and surface water resources, soil erosion, flooding potential, water quality and plant-derived wastewater generation and disposal. In addition, evaluate construction, operation and maintenance of the facilities and conduct investigations to determine if violations of the program's regulations, the Energy Commission's conditions of certification, or the California Environmental Quality Act (CEQA) have occurred.

Transportation Engineer, Civil 2000 to 2010
California Department of Transportation (Caltrans), District 3, Sacramento, CA
As Project Engineer in the Office of Design, identified storm water quality issues along public highways within the Tahoe Lake area and designed appropriate features in an effort to preserve and enhance the unique natural environment; and prepared reports evaluating alternatives and proposing a design concept and scope for development and programming.

Designed drainage systems for highways throughout Northern California to comply with Caltrans standards, including: analysis of site hydrology and hydraulic design; storm water management near impaired water bodies; and preparing layouts and construction details for contract plans.

Also performed engineering inspections of State contract construction projects and enforced contractor's compliance with plans and State specifications. Duties include: assisting Resident Engineer in re-designing areas where the contract plans conflicted with field conditions; performing inspections of construction site activities; and managing problems that develop in the field.

Waste Management Engineer 1997 to 2000
California Integrated Waste Management Board, Sacramento, CA
Reviewed and analyzed construction and demolition (C&D) waste handling, processing, and treatment technologies to minimize waste disposal and increase the use of recycled material into useful products. Organized outreach (workshops, conference booth, fact sheets) of C&D programs to industry audiences.

DECLARATION OF
Eric Veerkamp

I, **Eric Veerkamp,** declare as follows:

1. I am presently employed by the California Energy Commission in the Compliance Office of the Siting, Transmission and Environmental Protection Division as a Compliance Project Manager.

2. A copy of my professional qualifications and experience is attached hereto and incorporated by reference herein.

3. I prepared the staff testimony on **General Conditions** for the **Palen Solar Electric Generating System Final Staff Assessment,** based on my independent analysis of the Application for Certification and supplement hereto, data from reliable documents and sources, and my professional experience and knowledge.

4. It is my professional opinion that the prepared testimony is valid and accurate with respect to the issue addressed therein.

5. I am personally familiar with the facts and conclusions related in the testimony and if called as a witness could testify competently thereto.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge and belief.

Dated: 8/6/2013 Signed: [signature]

At: Sacramento, California

ERIC W. VEERKAMP, AICP

Compliance Project Manager

EDUCATION
B.S. Business Administration (Human Resources Mgmt.); Minor in Environmental Studies

PROF. AFFILIATIONS
American Institute of Certified Planners (AICP), American Planning Association (APA), Association of Professionals (AEP), Toastmaster International (past member)

COMMUNITY INVOLVEMENT
California Academic Decathlon volunteer, 2009; St. Robert School parent volunteer

Mr. Veerkamp has over 22 years of Planning, Environmental, and Project Management experience.

PLANNER III, COMPLIANCE PROJECT MANAGER

California Energy Commission (June 2011 – Present)

Mr. Veerkamp is currently the Compliance Project Manager for the Genesis Solar Energy Project (GSEP), which is currently under construction, approximately 70% complete. Mr. Veerkamp also has Compliance oversight responsibility on operational projects, including Metcalf, Colusa, Sunrise, Starwood, Metcalf, and Palmdale

PLANNER II

California Energy Commission (September 2010 – June 2011)

Mr. Veerkamp drafted the Land Use Preliminary Staff Assessment for the Hydrogen Energy, California (HECA) project, and the Final Staff Assessment for the Transmission Line Alternatives Analysis, supplementing the Traffic and Transportation Section for the Palmdale Hybrid Power Plant (PHPP). Mr. Veerkamp was also been assigned Traffic and Transportation and Visual compliance responsibilities for G.W. Tracy and Land Use and Socioeconomic compliance for Sutter.

INDEPENDENT CONTRACTOR

EData Corporation. (2010)

Drafted CEQA sections for proposed Jamul Indian Village commercial project in San Diego County, including Traffic and Transportation Alternatives Analysis, Visual Resources, and Land Use. Review and respond to public agency comments on NEPA EIS for proposed Soboba Tribal gaming facility, also in San Diego County.

SENIOR ASSOCIATE

Raney Planning & Management, Inc. (2006 – 2010)

With Raney Planning & Management, Inc., Mr. Veerkamp served as Housing Element Project Manager. Clients included the Cities of Calexico, El Centro, Brawley, Colfax, Hollister, and Oroville. Mr. Veerkamp also assisted with preparation of CEQA environmental documents, served the City of Wheatland as contract planning staff; and managed prevailing wage contracts for Laurin Associates (a division of Raney). Accomplishments include preparing an award winning City-wide Visioning document for the City of Wheatland, and a growth management rating system for the City of Hollister.

DECLARATION OF
Carol Watson

I, **Carol Watson,** declare as follows:

1. I am presently employed by the California Energy Commission in the Environmental Office of the Siting, Transmission and Environmental Protection Division as a Staff Biologist.

2. A copy of my professional qualifications and experience is attached hereto and incorporated by reference herein.

3. I helped prepare the staff testimony on **Biological Resources** for the **Palen Solar Electric Generating System Final Staff Assessment,** based on my independent analysis of the Application for Certification and supplement hereto, data from reliable documents and sources, and my professional experience and knowledge.

4. It is my professional opinion that the prepared testimony is valid and accurate with respect to the issue addressed therein.

5. I am personally familiar with the facts and conclusions related in the testimony and if called as a witness could testify competently thereto.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge and belief.

Dated: 8-6-2013 Signed: Carol Watson

At: Sacramento, California

Carol Watson
Sacramento, CA

WORK EXPERIENCE

California Energy Commission **2/2010 - Present**
Sacramento, CA
Siting Transmission & Environmental Protection Division

As staff biologist, primary duty analysis of power plants over 50MW: solar thermal, photovoltaic (pending litigation), natural gas, and coal technologies. Analyze applications to permit projects, conduct CEQA-certified regulatory program under the Warren-Alquist Act, perform scoping and coordination with resource agencies, the public, “intervenors” to the applicant’s process, formulate and recommend mitigation, and defend analysis under oath before Energy Commission Commissioners. Provide compliance oversight for permitted projects during all stages: construction, operation, and closure, and ensure proper implementation of mitigation and resolve biological-related construction issues. Synthesize developing regulations (REAT agency, DRECP Sec. 10 process among others) and relevant legislation to ensure Energy Commission compliance. Coordinate with— and negotiate— solutions with diverse entities as BLM, USWS, Water Quality Control Board, US Army Corps of Engineers, Governor’s Office liaisons to the Energy Commission, private interest groups, and solicitors working on behalf of these interests.

Parsons Corporation **10/2004 - 12/2009**
Las Vegas, Nevada

Principal Scientist

Worked in-house with client, Southern Nevada Water Authority. Served as Principal scientist from 11/2008 to 2/2010. Prepared Environmental Species Act Section 7 Permit for the Southern Nevada Water Authority Pipeline Project. Species included desert tortoise and 10 other Mojave and Great Basin aquatic and upland species. Perform general site surveys, spring snail counts, sage grouse telemetry, mist netting for bats, Amargosa toad surveys in Death Valley, Nevada, and assist the Nevada Department of Wildlife with bat telemetry studies.
From 2004-2008 served as project scientist. Duties included mapping riverbank vegetation of the Virgin river, from the lower reach in Nevada through the confluence with Lake Mead. Ground-truthed plant assemblages based on aerial imagery and 3-dimensional (stereoscopic) views of vegetation. Familiar with cadastral and rastral imagery analysis.
From 9/2005-11/2008 served on consultant basis. Prepared EIS/EIR analysis for impacts to peregrine falcon and special status bat species from the Gerald Desmond Bridge Project, in the Port of Long Beach, California.

Enercon **9/2005-11/2007**
Tulsa, Oklahoma

Project Biologist

Fulltime from 7/2008-11/2008, consulting status from 9/2005 to 5/2007. Served as project biologist, performing a range of work from baseline surveys for the Oklahoma Department of Transportation, preparing NEPA documents, preparing and responding to Requests for Proposals and Requests for Qualifications. Representative projects include coordination of environmental studies and preparation of an Environmental Assessment for the Federal Highway Administration, on behalf of Kellogg Engineering, in Rogers County, Oklahoma. Conducted public scoping and agency solicitation, attending county plenary sessions as technical environmental consultant. Prepared an Environmental Information Document for the Environmental Protection Agency for the expansion of the Rural Water District #3 Tacora Water Treatment plant in Rogers County, OK. Conduct protocol surveys for the federally endangered American burying beetle on behalf of clients such as Chesapeake Operating Systems, OKDOT, and Panther Energy Company, surveyed new pipeline routes from Oklahoma though northern Texas for OG&E.

Representative Project: City of Moreno Valley, Riverside Co., California. Prepared Caltrans' Natural Environment Study for improvements to SR-60 at the Moreno Beach Drive and Nason Street interchanges. Studies included oversight of a jurisdictional delineation of wetlands and waters of the U.S., and coordination with project engineers to determine project boundaries and impacts. Developed mitigation in conformance with the Western Riverside County Multiple Species Habitat Conservation Plan.

BonTerra Consulting **2/2004 – 10/2004**
Pasadena, California

Wildlife Biologist

Draft RFQ/RFP, perform general biological surveys on behalf of public and private sector clients, and prepare CEQA/NEPA documentation. Representative Project: Plum Canyon Development, Los Angeles Co., California: Conducted salvage (pitfall trapping & grubbing salvage) and relocation of sensitive and local populations of reptiles and amphibians. Species handled included Western spadefoot toad, coastal western whiptail, and silvery legless lizard. Coordinated with CDFG regarding species of special concern, drafting relocation plans, and assisted with developing a protocol to simulate and force spring emergence and subsequent relocation of spadefoot toads prior to grubbing.

Sapphos Environmental **12/2000-2/2003**
Pasadena, California

Wildlife Biologist

Responsible for all phases of project management and biological technical work. Responded to and prepared RFP/RFQ, designed and conducted environmental study sufficient to project details (*i.e.* determination and development of appropriate ESA, NEPA, CEQA, Clean Water Act permits); and prepared environmental documentation. Prepared and conducted all public noticing and scoping per regulations, and prepared as technical consultant before the county and city and planning committees of Ventura and Los Angeles.

Representative Project: Ahmanson Ranch, Ventura County, California: Conducted long-term monitoring of a population of California red-legged frog with detailed notes as to location, behavior, and conditions. Assisted permitted biologists in placing passive integrated transponders, or PIT tags, as part of a radio telemetry study designed to aid understanding of habitat use and foraging distances. Assisted with the preparation of a Biological Assessment for an Endangered Species Act Section 7 consultation. Managed the design and creation of enclosed habitat and a captive breeding program. Prepared monthly status reports, and conducted various studies at the Ahmanson Ranch, including San Fernando Valley spineflower introduction studies, seed counts and collections, and oak tree surveys and assessments.

EDUCATION

M.S. Zoology, Eastern Illinois University **2000**
Focus: environmental ecology; population dynamics
Paid Teacher's Assistantship

B.S., Biology, Western Michigan University 1998
Chemistry minor

RELEVANT TRAINING

CPR Certified (2011, Energy Commission)
Desert Tortoise Surveying, Monitoring, and Handling Workshop, (2000)
BLM certified to survey for the flat-tailed horned lizard (2001)
California red-legged frog workshop (2001)
Passed U.S. Fish and Wildlife Service survey exam for El Segundo blue butterfly (2002)
American Burying Beetle Bait-away Surveys and Pitfall Trapping (performed under a permitted biologist' supervision), 2006-2007.

DECLARATION OF
Casey Weaver, CEG

I, **Casey Weaver,** declare as follows:

1. I am presently employed by the California Energy Commission in the Engineering Office of the Siting, Transmission and Environmental Protection Division as a Engineering Geologist.

2. A copy of my professional qualifications and experience is attached hereto and incorporated by reference herein.

3. I prepared the staff testimony on **Geology and Paleontology** for the **Palen Solar Electric Generating System Final Staff Assessment,** based on my independent analysis of the Application for Certification and supplement hereto, data from reliable documents and sources, and my professional experience and knowledge.

4. It is my professional opinion that the prepared testimony is valid and accurate with respect to the issue addressed therein.

5. I am personally familiar with the facts and conclusions related in the testimony and if called as a witness could testify competently thereto.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge and belief.

SUMMARY OF EXPERIENCE:

Certified Engineering Geologist with over 20 years of environmental and geotechnical consulting experience. Experience includes remedial investigations and feasibility studies (RI/FS), groundwater investigations, corrective action plans, landfill studies (SWATs, siting, closure), preliminary environmental site assessments (PESA, Phase I), regulatory compliance (RCRA/CERCLA), geotechnical investigation/evaluation, geologic hazard evaluations, active fault evaluations, seismic studies, landslide evaluation/repair, foundation suitability studies, personnel management and business development.

EDUCATION:

B.S. Geology, Humboldt State University, Arcata, CA, 1981
University of California, Davis Extension Courses

REGISTRATIONS/LICENCES/CERTIFICATIONS:

Certified Engineering Geologist, California
Registered Geologist, California, Oregon, Arizona
Registered Environmental Assessor
OSHA 1910.120 Hazardous Waste Operations and Emergency Response - 40hr
OSHA 1910.120 Hazardous Waste Operations and Emergency Response - Supervising Operations at Hazardous Waste Sites.

PROFESSIONAL HISTORY:

2008 to Present

Engineering Geologist
California Energy Commission, Sacramento, CA

Duties within the Geosciences Unit of the Engineering Office in the Siting, Transmission, Environmental Protection Division include review and evaluation of applications for certification of thermal power plants within the state of California. The focus of the work is on sensitive project sites that may have issues involving geologic hazards, paleontological, groundwater and surface water resources, soil erosion, flooding potential, water quality and plant-derived waste generation and disposal. In addition, evaluate construction, operation and maintenance of the facilities and conduct investigations to determine if violations of the program's regulations, the Energy Commission's conditions of certification, or the California Environmental Quality Act (CEQA) have occurred. Selected as the Energy Commission's seismic expert and CEC's representative on the multi-jurisdictional Independent Peer Review Panel which reviews and provides comments to major utilities regarding their seismic investigations and evaluations conducted for California's nuclear power plants.

2001 to 2008

Engineering Geologist
State Water Resources Control Board, Headquarters, Sacramento, CA

With the UST Enforcement Unit, under direction from the State Attorney General's Office, conducted inspections of UST systems to evaluate compliance with 1998 upgrade requirements. This work culminated in the largest settlement of its kind in the nation's history. In addition, conducted surveillance of unlawful discharges from remediation systems and conducted investigations of UST Fund fraud cases.

With the USTCF Technical Review Unit, evaluated the technical elements of USTCF claims.

With the Division of Financial Assistance, assisted with the development of program policy for the Agricultural Water Quality Grant Program ($46 million) and the Integrated Water Quality Grant Program ($380 million), participated in stakeholder workshops, contributed to multijurisdictional work groups for program development and implementation.

With the Office of Enforcement, conducted investigations of operator misconduct, wrote enforcement investigation reports and prepared disciplinary letters.

1998 to 2001

Senior Engineering Geologist
BSK & Associates, Rancho Cordova, CA

Designed and directed hydrogeologic investigations for use with environmental remediation projects. Supervised field personnel installing groundwater monitoring wells, conducting aquifer tests & SVE pilot tests, reviewed reports and workplans, and conducted business development.

Conducted review of Alquist-Priolo active fault hazard reports as county geologist for Kern County.

1993 to 1998

Senior Geologist, Geoscience Team Leader and RI/FS Task Leader
LAW Engineering and Environmental Services, Inc., Sacramento, CA

As Geoscience Team Leader, responsible for career development, training and personnel management of ten employees. This group consisted of 3 senior-level geologists, 4 project level geologists and scientists, 2 junior level geologists and 1 technician.

As RI/FS Task Leader, responsible for the development of cost estimates/budgets, preparation of Work Plans and Sampling and Analysis Plans, management of field activities, data collection and documentation associated with the investigation of 15 Installation Restoration Program sites at Beale Air Force Base awarded under several Delivery Orders with combined project budgets of $18 million. Also responsible for aerial photographic interpretations associated with a basewide (23,000 acres), Preliminary Assessment, and preparation of a basewide Hydrogeologic Evaluation Report.

1990 to 1993

Senior Project Manger/General Manager
Earthtec, Ltd., Roseville, CA

Management of Environmental Department, business development, preparation of cost estimates and proposals, client and regulatory agency interface, supervision and training, report writing, technical review, budget management, and quality control. Initiated and supported the development of company's wetland and wildlife departments. Typical projects included preliminary site assessments, soil vapor studies, detailed hydrogeologic evaluations, waste plume delineations, and development of remediation alternatives associated with landfills, service stations, bulk oil facilities and other potentially contaminated sites.

1981 to 1990

Project Geologist
SHN Group, Inc. Eureka, CA

Managed project work directed toward solving environmental issues at variably contaminated sites and provided geotechnical information for land development and construction. Responsibilities included development of cost estimates/budgets, planned and supervised field operations, collected and interpreted subsurface information, evaluated areas traversed by Alquist-Priolo Special Studies Zones and sites subject to slope stability hazards. Typical projects included geotechnical evaluations and geologic hazard studies for major subdivisions, hospitals, schools, lumber companies, run-of-the-river hydroelectric projects, underground storage tank sites, and solid waste landfills.

1979 to 1981 **Geologist/Seismologic Technician**
Woodward-Clyde Consultants, San Francisco, CA

Designed and operated a laboratory model to study surface effects of thrust faulting in connection with seismic evaluation studies for the PG&E Humboldt Bay nuclear reactor. In addition, installed and operated field seismographs in the Humboldt Bay region.

DECLARATION OF
Lisa Worrall

I, **Lisa Worrall**, declare as follows:

1. I am presently employed by the California Energy Commission in the Environmental Office of the Siting, Transmission and Environmental Protection Division as a Planner II.

2. A copy of my professional qualifications and experience is attached hereto and incorporated by reference herein.

3. I prepared the staff testimony on **Socioeconomics** for the **Palen Solar Electric Generating System Final Staff Assessment,** based on my independent analysis of the Application for Certification and supplement hereto, data from reliable documents and sources, and my professional experience and knowledge.

4. It is my professional opinion that the prepared testimony is valid and accurate with respect to the issue addressed therein.

5. I am personally familiar with the facts and conclusions related in the testimony and if called as a witness could testify competently thereto.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge and belief.

Dated: August 2, 2013 Signed: Lisa Worrall

At: Sacramento, California

LISA WORRALL

Summary

- Over eleven years of environmental analysis experience.
- Preparation of environmental documents in compliance with the California Environmental Quality Act (CEQA), National Environmental Policy Act (NEPA), California Energy Commission siting regulations, and federal, state and local laws, ordinances, regulations and standards (LORS).
- Projects include thermal power plants, private residential and commercial development, county and public works, and state transportation.

Employment Experience

California Energy Commission
Planner II Sacramento, California
January 2010 to Present

- Prepare an independent CEQA analysis of the environmental impacts from thermal power plants related to land use and socioeconomics.
- Evaluate projects in accordance with CEQA, the California Energy Commission siting regulations, and federal, state and local LORS.
- Review information provided by the project applicant and other resources to assess the environmental effects of energy facility proposals

Sacramento County Department of Environmental Review & Assessment
Associate Environmental Analyst Sacramento, California
April, 2006 – May, 2009

- Prepared a variety of environmental documents in compliance with CEQA, NEPA and local, state and federal LORS.
- Conducted project site assessments, reviewed engineering plans, and researched and interpreted scientific data for project impact analysis.
- Managed multiple public works and private development projects with a variety of environmental concerns and overlapping deadlines.
- Maintained effective relationships with other Sacramento County departments, agencies, and service providers to ensure comments and recommended conditions of project approval were obtained and any associated environmental impacts assessed.

Analytical Environmental Services Sacramento, California
Associate April, 2004 – October, 2005

- Interpreted highly technical traffic impact studies, utilizing the information to develop a traffic impact assessment chapter for use in a variety of environmental documents complying with CEQA, NEPA, and county and city transportation policies and codes.
- Managed the preparation of traffic studies, including developing the scope of study, securing the contract, and reviewing the work product.
- Managed multiple private development projects simultaneously under tight deadlines. Clients included Native American tribes and cities.
- Coordinated with state, county and city officials in the development of traffic study methodology, parameters and assumptions for proposed projects.

- Worked closely with transportation engineers to understand the complexities of each project's specific traffic impacts.

California Department of Transportation (Caltrans) Fresno, California
Associate Environmental Planner March, 2003 – March, 2004
Environmental Planner August, 2000 – March, 2003

- Prepared all levels of environmental documentation for transportation projects in compliance with CEQA and NEPA.
- Coordinated and interpreted environmental technical studies for incorporation into the environmental document and for explanation to other team members, agencies, and the public.
- Managed and represented environmental concerns with other functional units.
- Led and participated in public outreach events.
- Coordinated project development with other Caltrans departments, agencies and the public.

Education

California State University, Northridge May, 2000
Bachelor of Arts in Geography

PALEN SOLAR ELECTRIC GENERATING SYSTEM (09-AFC-7C)
FINAL STAFF ASSESSMENT – Part A

Amendment to Palen Solar Power Project

PREPARATION TEAM

Executive Summary .... Christine Stora

Introduction .... Christine Stora

Project Description .... Christine Stora

Environmental Assessment

~~Air Quality.. Jacquelyn Leyva Record~~

Biological Resources............Ann Crisp, William B. Haas, Chris Huntley, Nick Lancaster and
 .... Carol Watson

~~Cultural Resources............................ Matthew Braun, Thomas Gates, and Michael McGuirt~~

Hazardous Materials Management .... Alvin Greenberg, Ph.D.

Land Use... James Adams

Noise and Vibration .... Shahab Khoshmashrab

Public Health .... Huei-An (Ann) Chu, Ph.D.

Socioeconomics .... Lisa Worrall

Soil and Water Resources.. Marylou Taylor, P.E.

Traffic and Transportation .... David Flores, Alvin Greenberg, Ph.D., Gregg Irvin, Ph.D.,
 .... Andrea Koch and Geoff Lesh, PE

Transmission Line Safety and Nuisance .... Obed Odoemelam, Ph.D.

Visual Resources .... Gregg Irvin, Ph.D. and William Kanemoto

Waste Management .... Christopher Dennis, PG

Worker Safety and Fire Protection .... Alvin Greenberg, Ph.D.

Engineering Assessment

Facility Design .... Shahab Khoshmashrab

Geology and Paleontology .... Casey Weaver, CEG

Power Plant Efficiency... Edward Brady

Power Plant Reliability... Edward Brady

Transmission System Engineering.. Mark Hesters and Laiping Ng

Alternatives... Jeanine Hinde

Compliance Conditions and Compliance Monitoring Plan........................ Eric Veerkamp

Project Assistant... Alicia Campos and Marci Errecart
