Dr. Steve Moore San Diego County Air Pollution Control District 10124 Old Grove Road San Diogo, CA 92131

Subject: Supplemental Information for the Carishad Energy Center Project (Application Numbers 905745 - 905748)

Dear Dr. Moore:

We are pleased to provide the following additional information requested in the San Diego County Air Pollution Control District's (SDAPCD) October 17, 2007 letter regarding the proposed Carisbad Energy Center Project.

#### BACT

Request 1: Please provide an estimate of potential particulate emissions resulting from the use of reclaimed water in the evaporative cooler at the combustion turbine inlet.

Response: As discussed in our October 10, 2007 letter to the SDAPCD, virtually all of the solids in the evaporative cooling water will be retained in the cooler blowdown and will not enter the turbine gas path. In addition, the gas turbine PM10 emission rate of 9.5 lbs/hr used for the proposed project was provided by the gas turbine vendor Siemens. The Siemens PM10 emission rate accounts for all project design features including the use of evaporative cooling. The Siemens PM10 emission rate reflects the use of evaporative cooling with a maximum water circulation rate of 110 galions per minute (total for both gas turbines) and a maximum cooling water total dissolved solids (TDS) level of 500 ppmrw. Please note that while the reclaimed water composition summary table in the AFC (Table 5.15F-1) shows TDS levels as high as approximately 922 ppmw, the cooling water for the evaporative cooling system will be processed by the reverse osmosis system to reduce the TDS level to design levels. Therefore, we do not believe that the proposed PM emission rates for the gas turbine need to be modified to account for the evaporative cooler.

Request 2: Provide the basis of the reclaimed water composition listed in Table 5.15F-1 in Appendix 5.15E.

Response: The basis for the reclaimed water composition shown in Table 5.15F-1 of the

Dr. Steve Moore Supplemental Application Information for the Carlsbad Energy Center Project December 18, 2007 Page 2 of 10

September 12, 2007 permit application package for the proposed project originated from an Encine Wastewater Authority technical report. A copy of this report is enclosed as Attachment 1.

#### **OPERATIONS ON LNG-DERIVED GAS**

Request 3: The latest fuel specification for the turbine model specified in the application.

Response: The fuel specifications used by Siemens to perform the gas turbine performance runs for the proposed project were included in the September 12, 2007 permit application package submitted to the SDAPCD (see Table 5.1-18). There have been no changes to the fuel specification used for turbine performance runs since that submittal. In regards to the fuel specifications for LNG-derived gas for the proposed project, enclosed as Attachment 2 is a copy of a letter from San Diego Gas & Electric Company (SDG&E) regarding the expected specifications of LNG-derived gas entering their system. While the SDG&E letter also makes a general statement about the effect on NOx and CO emissions associated with the use of LNG-derived gas, SDG&E defers to the equipment vendor to provide the actual expected effect on emissions from the use of LNG-derived gas.

Request 4: A guarantee that the combustion turbine in combination with the add-on emission control system will be able to meet the proposed exhaust stack emission limits in the application when operated over the expected Wobbe No. range of 1335-1385 and a description of any measures and ancillary equipment needed to achieve this guarantee.

Response: Enclosed as Attachment 3 is a copy of a letter from Siemens concluding that the gas turbine emission levels proposed for the CECP will be achieved with a natural gas Wobbe Index ranging from 1335 to 1385 Btu/scf. Please note that the Siemens acceptable range of natural gas Wobbe Index is broader than that expected by SDG&E in their system with LNG derived natural gas (see Attachment 2). In addition, the CEC staff concluded recently in the final staff assessment for the Colusa Generating Station (06-AFC-9) that the use of LNG would not significantly impact the air pollution emissions for that power plant. A copy of the relevant pages from this document along with a copy of the supporting technical report are included as Attachment 4. Since both the Colusa Generating Station and the proposed project are gas turbine combined cycle designs, a similar conclusion can be reached for the proposed project with respect to the use of LNG.

Request 5: The maximum allowable amount of ethane, propane, and/or higher hydrocarbons in the fuel that the combustion turbine in combination with the add-on emission control system can tolerate and still meet the proposed emission limits in application.

Response: As discussed above, it is expected that emissions performance will account for the range of fuel properties expected for the proposed project, which will be any fuel

Dr. Steve Moore Supplemental Application Information for the Carlsbad Energy Center Project December 18, 2007 Page 3 of 10

that can be legally delivered to the site under the SDG&E tariff. In addition, as discussed above, the gas turbine emission levels proposed for the project are expected to be achieved for a range in the Wobbe Index of 1335 to 1385 Btu/scf. This acceptable variation in Wobbe Index is broader than that expected by SDG&E for their system with LNG derived natural gas. Since Wobbe Index is an important indicator of the hydrocarbon composition of fuel gas, the information provided by Siemens (see Attachment 3) also means that the CECP will meet the proposed gas turbine emission levels for the expected range of natural gas hydrocarbon compositions for the project.

- Request 6: The maximum allowable rate of change in Wobbe No. that the combustion turbine in combination with the add-on emission control system can tolerate and still meet the proposed emission limits in application.
- Response: As discussed above, the information provided by SDG&E and Siemens indicates that the proposed emission levels for the gas turbines will be met over the Wobbe Index range expected for the project.
- Request 7: The maximum allowable rate of change in ethane, propane, and/or higher hydrocarbons fuel content that the combustion turbine in combination with the addon emission control system can tolerate and still meet the proposed emission limits in application.
- Response: As discussed above, the information provided by SDG&E and Siemens indicates that the proposed emission levels for the gas turbines will be met over the Wobbe Index range expected for the project. Since Wobbe Index is an important indicator of fuel gas hydrocarbon composition, this information also shows that the emission levels for the gas turbines will be met over the expected range of natural gas hydrocarbon compositions expected for the project.

#### **AOIA MODEL**

- Request 8: If the air impact modeling was done using AERMOD version 06341, please resubmit the air impact modeling using the latest version of AERMOD or provide a demonstration that, for purposes of this project, AERMOD version 06341 and AERMOD version 07026 give the same results.
- Response: The modeling included in the September 12, 2007 permit application package for the proposed project was inadvertently performed using a slightly older version of AERMOD (version 06341), rather the current version of AERMOD that was available near the end of January 2007 (version 07026). The modeling for the proposed project was re-run using AERMOD version 07026 and the results are summarized in Attachment 5. As shown in Attachment 5, there are only minor changes in the modeling results due to the use of the current version of AERMOD. The minor changes in ground-level concentrations in revised Table 5.1-28 can be

Dr. Steve Moore
Supplemental Application Information for the Carlsbad Energy Center Project
December 18, 2007
Page 4 of 10

either increases or decreases because the change in AERMAP produced slightly higher and lower ground elevations in different locations where modeling maxima occurred for different pollutant-averaging time combinations. These slight up and down changes in ground elevations also explain the slight up and down changes in maximum potential health impacts shown in revised Table 5.9-6. The detailed modeling files are included in the attached modeling CD.

#### **AOIA ANALYSIS**

Request 9: In this case, the District requires an analysis considering the impacts on days when the background concentration does not exceed the standard. Please provide such an analysis for the impact of PM<sub>10</sub> with respect to the state 24-hour standard. The District meteorology staff should be contacted for details of the analysis procedure.

Based on recent discussions between Sierra Research and the SDAPCD Response: modeling/meteorology group, the PM<sub>10</sub> analysis for the proposed project must include a review of the three years' worth of background ambient PM10 data collected at the Escondido monitoring station to identify days when the ambient PM<sub>10</sub> levels are just below the state 24-hr standard of 50 µg/m<sup>3</sup>. For these days, the project's maximum modeled 24-hr PM<sub>10</sub> impact should be added to these ambient levels to determine if the proposed project will cause any additional exceedances of the state 24-hr average PM<sub>10</sub> standard. Included as Attachment 6 is a summary of the Escondido monitoring station ambient PM<sub>10</sub> levels for the three-year look-back period (2004 to 2006). As shown by these data, the PM<sub>10</sub> levels just under the state 24-hr standard during this period are 42 µg/m<sup>3</sup> (2<sup>nd</sup> maximum) during 2004 and 43 μg/m<sup>3</sup> (2<sup>nd</sup> maximum) during 2006. No 2<sup>nd</sup> maximum levels are histed for 2005 because the maximum monitored PM<sub>10</sub> level during that year is not above the state 24-hr standard. If the proposed project's maximum 24-hr PM<sub>10</sub> impact of 2.2 µg/m<sup>3</sup> (see Attachment 5 for revised modeling results) is added to these background levels, the totals remain below the state 24-hr standard of 50 µg/m<sup>3</sup>. Consequently, the proposed project will not cause any additional exceedances of the state 24-hr PM<sub>10</sub> standard.

Request 10: Provide a key to identify all of the source groups used in the AERMOD calculations. In addition, provide a plain language summary of the electronic files submitted with the application so that they can be easily related to the information in the report. The summary should include a description of each source group being modeled.

Response: An improved "read me" file for the revised air quality impact modeling is included in the enclosed modeling CD. This file includes the identification of all source groups and a "plain language" summary of the electronic modeling files. A hardcopy of this file is included as Attachment 7.

Dr. Stève Moore Supplemental Application Information for the Carlsbad Energy Center Project December 18, 2007 Page 5 of 10

Request 11: Confirm that air quality impact calculations were made without considering emissions decreases from the eventual retirement of the three existing boilers.

Response:

All ambient air quality impacts discussed in the September 12, 2007 permit application package for the proposed project and included in Attachment 5 of this letter are for the new equipment only and do not include any benefits associated with the shutdown of the three existing boilers at the Encina Power Station.

#### HRA ANALYSIS

Request 12: Explain why cancer risk is calculated using more than the Office of Environmental Health Hazard Assessment (OEHHA) Derived (Adjusted) Method. It makes the review process more cumbersome and makes it more difficult for the public to evaluate the analysis and report. Moreover, it results in much lengthier AERMOD model runs and reports than are needed.

Response:

Table 5.9-6 in the AFC Public Health Section 5.9 reports cancer risk using only the OEHHA's Derived (Adjusted) Method as requested by SDAPCD staff. The other methods of calculating cancer risk are also included in the air dispersion modeling for the following reasons:

- They are described in OEHHA guidance documents;
- They are available in the HARP software published by the ARB;
- They provide more complete information on the potential range of cancer risk;
- They satisfy the CEQA requirement for public disclosure of the full range of
  potential environmental impacts. The additional risk methods were included in
  response to a request from the staff of the California Air Resources Board
  several years ago.
- Request 13: A key to identify all of the source groups used in the AERMOD calculations. In addition, provide a plain language summary of the electronic files submitted with the application specifically for the health risk assessment so that they can be easily related to the information in the report. The summary should include a description of each source group being modeled.

Response: Enclosed as Attachment 7 is a "plain language" summary of the electronic files related to the health risk assessment (HRA) performed for the proposed project. This summary includes the identification of the source groups used in the AERMOD runs.

Request 14: Information on whether health risk calculations were made with or without considering emissions decreases from the eventual retirement of the three existing boilers.

Response: The HRA performed for the proposed project does not include emission decreases

Dr. Steve Moore Supplemental Application Information for the Carlsbad Energy Center Project December 18, 2007 Page 6 of 10

from shutting down existing Encina Power Station Boiler Units 1-3.

Request 15: A separate calculation of health risk for startup and commissioning activities and an explanation as to how this risk was analyzed and incorporated into the overall health risk estimates including a description of exactly which commissioning activities were analyzed. If estimates of health risk under these conditions are expected to be negligible, this needs to be clearly demonstrated.

Response:

Separate calculations of health risk for startup and commissioning are not needed because the conservative toxic air contaminant (TAC) emission rate calculation starts with the highest possible hourly heat input rate under any operating condition (i.e., commissioning, startup, and normal) as indicated in the September 12, 2007 permit application package for the proposed project (see Footnote 2 to Tables 5.9B-1 and 5.9B-2 "short-term commissioning containing the uncontrolled emission factors for acrolein, benzene, and formaldehyde"). Maximum possible hourly and annual fuel flows were also used for the HRA (see Tables 5.9B-1 and 5.9B-2. Footnotes 4 and 6). Therefore, no higher TAC emission rates can be generated by separate calculations for startup and commissioning. All commissioning activities are automatically considered by the above approach because the TAC emission factors are on a fuel basis (i.e., MMscf of natural gas), and the maximum possible hourly and annual fuel flows are used. The stack exhaust conditions of temperature and velocity are selected to be the combination determined by screening runs for 1hour and annual averaging times and three ambient temperatures (i.e., extreme hot, annual average, and extreme cold). The worst-combination exhaust conditions for the annual averaging time give the maximum potential cancer risk and non-cancer chronic health hazards, while the worst-combination exhaust conditions for the 1hour averaging time give the maximum potential non-cancer acute health hazard.

Request 16: Identification of the computer file(s) that contain the maximum health risk impacts will be found [sic]. Health risk results should not just be stated, but should be clearly referenced.

Response:

The HRA performed for the proposed project is based on maximum potential gas turbine fuel flow rates, maximum TAC emission rates, and maximum possible ground-level concentrations. The maximum potential health impacts are contained in the computer files described in Attachment 7.

#### STARTUP, SHUTDOWN, AND COMMISSIONING

Request 17: Provide representative measured or calculated minute-by-minute exhaust stack temperature, fuel flow rate, oxygen content, and turbine load and controlled and uncontrolled carbon monoxide (CO) emissions, volatile organic compound (VOC) emissions, and oxides of nitrogen (NOx) emissions during a representative warm startup (overnight or shorter shutdown), cold startup (weekend shutdown) and supporting information. The data should extend until the steam turbine has reached

Dr. Steve Moore
Supplemental Application Information for the Carlsbad Energy Center Project
December 18, 2007
Page 7 of 10

#### full load.

Response:

Minute-by-minute emissions and/or stack parameters during gas turbine startups, shutdowns, or commissioning tests are not available from Siemens. The modeling of gas turbine startups, shutdowns, and commissioning tests for the proposed project was performed using stack parameters associated with the gas turbine operating at 50% load for an entire hour. The hourly emission rates used for this modeling were provided by Siemens and are summarized in Tables 5.1B-7, 5.1B-8, and 5.1B-9 of the September 12, 2007 permit application package for the proposed project. As shown in these tables, Siemens provides the total mass emissions that would occur during the first 22 minutes of a gas turbine startup. Based on the footnotes for Table 5.1B-8, within the first 12 minutes of the startup the gas turbine achieves 100% load. The CO control during the first 12 minutes is 20%, with CO control achieving 90% following this period. Full NOx control is achieved after 22 minutes. For the remainder of the hour it is assumed the gas turbine is operating with normal emissions at a gas turbine load of 100%. It would be possible to break up a gas turbine startup hour into the following three parts:

- First 12 minutes: gas turbine load ranges from full speed no load to 100% load, 20% CO control, NOx control varies an unknown amount
- Next 10 minutes: gas turbine at 100% load, full control of CO, NOx control varies an unknown amount
- Final 38 minutes: gas turbine at 100% load, full control of NOx and CO

Since the gas turbine achieves 100% load within 12 minutes, the modeling analysis performed for the proposed project is conservative since it assumes the gas turbine is operating with dispersion parameters comparable to 50% load for the entire hour during a startup. While it would be possible to break up the startup hour into three parts and model each part separately, the results are not expected to be higher then those found using the conservative 50% gas turbine load approach.

Request 18: Provide representative measured or calculated minute-by-minute exhaust stack temperature, fuel flow rate, oxygen content, and turbine load and controlled and uncontrolled NOx and CO emissions, VOC emissions, and NOx emissions during a representative shutdown and supporting information.

Response: Please see the response to Request 17.

Request 19: Provide the basis for assuming that CO emissions are reduced by 20% during the first 12 minutes of a startup and by 90% during the final 10 minutes of a startup during normal operations (Table 5.1 B-8).

Response: The CO level control of 20% during the period from ignition to 100% gas turbine load (12 minute period) and a CO control level of 90% after the gas turbine achieves 100% load were provided by Siemens. Please see startup note number 5 in Table 5.1B-8 of the September 12, 2007 permit application package for the

Dr. Steve Moore
Supplemental Application Information for the Carlsbad Energy Center Project
December 18, 2007
Page 8 of 10

proposed project.

Request 20: The approximate minimum load at which the combustion turbine is able to achieve the proposed best available control technology emission limits for and CO.

Response: The gas turbines will be able to meet their proposed best available control technology (BACT) CO emissions limit of 2.0 ppmv @ 15% O<sub>2</sub> during normal operation for gas turbine loads ranging from 60% to 100%.

Request 21: During combustion turbine commissioning operations without add-on air pollution control equipment in place, provide exhaust stack temperature and oxygen content when the turbine is operating at full speed no load, 10% load, 25% load, and 40% load.

Response: Enclosed as Attachment 8 are the stack parameters for a gas turbine operating at full speed no load (FSNL), 10% load, 25% load, and 40% load (see operating cases 16 to 20 and 27 to 31). Please note that the enclosed gas turbine performance runs were provided by Siemens for units proposed for the El Segundo Generating Station, which are identical to the units proposed for CECP. Consequently, the ambient site conditions (ambient temperature and humidity) shown in the enclosed performance runs are different than those for the CECP. However, these differences in ambient conditions between the two project sites will have minimal effects on the stack parameters at low gas turbine loads (40% load and less).

Request 22: Details of combustion turbine commissioning activities indicating the approximate amount time in each operating mode during the activity.

Response: The detailed gas turbine commissioning schedule, including the duration of each commissioning test, is shown in Table 5.1B-9 of the September 12, 2007 permit application package for the proposed project.

#### TOXIC AIR CONTAMINANT EMISSION FACTORS

Request 23: The footnotes to Table 5.9B-1 indicate that the emission factors for acrolein, benzene, and formaldehyde are based on Table 3.1-1 in EPA's AP-42 emission factor compilation. In addition, the footnotes indicate that no control factor for the oxidation catalyst has been applied to these emission factors to account for startups when the oxidation catalyst may have less or no effectiveness. However, a comparison of Table 5.9B-1 to Table 3.1-1 in AP-42 indicates that control factors of approximately 50%, 75%, and 50% have been applied to the AP-42 acrolein, formaldehyde, and benzene emission factors, respectively to generate the emission factors in Table 5.9B-1. At a minimum (see below), please revise the hourly emission rates in Table 5.9-1 and the health risk assessment to reflect no emission control factor for acrolein, formaldehyde, and benzene or provide a justification of the control factors used.

Dr. Steve Moore Supplemental Application Information for the Carlsbad Energy Center Project December 18, 2007 Page 9 of 10

Response:

The commentor's observation about the reduced emission factors is correct, except that the approximate 75% reduction was applied to benzene, not formaldehyde; and the correct AP-42 table is Table 3.1-3, not Table 3.1-1. The footnote should have been worded differently to note that the emission factors in Table 5.915-1 of the September 12, 2007 permit application package were purposefully reduced to reflect the ability of the oxidation estalyst to control emissions of these three toxic air contaminants during normal gas turbine operation.

The footnote would have been less confusing if it had been worded as follows: "All factors are from AP-42, Table 3.1-3, 4/90 except PAHs, hexane, propylene, and the following three that are reduced according to the control effectiveness of the oxidation estalyst: acrolein (42.4%), beazene (72.8%), and formaldehyde (49.3%). Individual PAHs, hexane and propylene are CATEF mean results because AP-42 does not include factors for these compounds. The substantial reduction in the emission factors for acrolein, beazene, and formaldehyde, which were taken from USEPA (2000), are based on measurements taken with and without a CO oxidation catalyst over the full range of turbine loads."

Request 24: The District also notes that the AP-42 emission factors or emission factors measured at high loads for toxic air contaminants may not be applicable to operations at low load operations that occur during startup, shutdown, and commissioning operations. The District may request the use of alternative emission factors for some air pollutants during low load operations. The District recommends providing any available test information for toxic air contaminant emissions for the model of combustion turbine proposed in the application, or a similar model, when operating at low load (i. e., not in the lean-premix combustion mode).

Response:

For early commissioning activities, when an oxidation catalyst is not installed, the uncontrolled emission factors for toxic air contaminants available in AP-42 Table 3.1-3, including those for acrolein, benzene, and formaldehyde, are used in emission calculations as presented in Table 5.1B-2 of the September 12, 2007 permit application package. For this table, the original Footnote 1 is accurate.

<sup>&</sup>lt;sup>1</sup> USEPA. Emission Factor Documentation for AP-42 Section 3.1 Stationary Gas Turbines, Table 3.4-1, April 2000, http://www.epa.gov/ttn/chiel/ap42/ch03/index.html.

Dr. Steve Moore
Supplemental Application Information for the Carlsbad Energy Center Project
December 18, 2007
Page 10 of 10

#### **ANNUAL EMISSION RATES**

Request 25: A comparison of Table 5.9B-1 to Table 3.1-1 in AP-42 indicates that control factors of approximately 50%, 75% and 50% have been applied to the AP-42 acrolein, formaldehyde, and benzene emission factors to generate the annual emission rates listed in Table 5.9B-1. Please revise the annual emission rates in Table 5.9-1 and the health risk assessment to reflect no emission control factor for acrolein, formaldehyde, and benzene or provide a justification of the control factors used.

Response:

As discussed in the response to Request 23, the commentor's observation about the reduced emission factors is correct, except that the approximate 75% reduction applied to benzene, not formaldehyde; and the AP-42 table is Table 3.1-3, not Table 3.1-1. The annual emission rates listed in Table 5.9B-1 of the September 12, 2007 permit application package (not Table 5.9-1) do not need to be revised to account for the higher uncontrolled emission factors of acrolein, benzene, and formaldehyde because the reduced emission factors are appropriate for normal operation. The higher uncontrolled emission factors of acrolein, benzene, and formaldehyde are properly used to calculate short-term emission rates for commissioning in Table 5.9B-2 of the September 12, 2007 permit application package because the oxidation catalyst is not installed for early commissioning activities.

If you have any questions regarding this application package, please contact me at (760) 710-2144 or Tem Andrews with Sierra Research at (916) 444-6666.

Sincerety,

Carlsbad Energy Center LLC

DISCHARGER:

CARLSBAD WATER RECYCLING FACILITY

ORDER NO. 2001-352

REPORT FOR: DECEMBER 2006

**REPORT DUE: FEBRUARY 1, 2007** 

OUR REVIEW OF THE ATTACHED SELF-MONITORING REPORT REVEALS THE FOLLOWING VIOLATION (S):

- The annual limit for manganese was exceeded over the last 12 month period (page 4).
- 2. On December 2, at 11:00 a.m. it was discovered that the turbidity meter had failed. The The meter reading had been 0.0 NTU since 6:00 a.m. We immediately stopped incoming flow to the plant. The meter was replaced and sub sequent readings were in compliance.

THE FOLLOWING REMEDIAL ACTION WILL BE TAKEN TO CORRECT THE MONITORING PROBLEMS LISTED ABOVE

- Currently performing a study to identify manganese levels in our service area.
- 2. Developing programming for a low level turbidity alarm in the SCADA system.

December 12, 2007

Mr. Tim Hemig Vice President NRG Energy 1817 Aston Avenue, Suite 104 Carlsbad, Ca 92008

RE: Gas Specifications of Gas Derived LNG from Energia Costa Azul (ECA) and NOx Emissions Levels

Dear Mr. Hemig,

As follow up to our meeting last week, you requested Gas Specifications for the gas derived LNG entering SDG&E territory starting in the first quarter of 2008... Also, you requested effects of NOx emissions levels due to the higher Wobbe on turbines.

Attached please find a comparison chart of the ECA Send-Out Gas Specifications for ECA Start-Up Supply, Primary Supplies, Potential Spot Supply and Current Pipeline Supply. This information is provided by Sempra LNG.

Generally, the emissions level will depend on whether the proposed turbine units are being equipped with an active tuning system and how effectively that system performs. Without active tuning one can expect the NOx and CO to change with Wobbe number. If the oxidation catalyst and SCR are designed properly, these increases can be controlled. However, your turbine manufacturer will need to confirm emission guarantees over the stated Wobbe range provided.

If there are any questions, please do not hesitate to contact me.

Sincerely,

Dinah Willier

# ATTACHMENT 3 SIEMENS LETTER

#### **SIEMENS**

December 17, 2007

Mr. Chris Doyle Regional Development Engineering Manager NRG West 1817 Aston Avenue, Suite 104 Carlsbad, CA 92008

Subject: Encina Plant Air Emissions

Dear Chris,

This letter is to confirm that the natural gas fired two unit Siemens 1x1 SCC6-5000F plant will be designed to meet the following air emissions limits between 60% and 100% gas turbine loads:

- Oxides of Nitrogen (NOx) = 2 ppmvd @ 15% O<sub>2</sub>
- Carbon Monoxide (CO) = 2 ppmvd @ 15% O<sub>2</sub>
- Volatile Organic Compounds (VOC) = 2 ppmvd @ 15% O₂
- Ammonia Slip (NH<sub>3</sub> Slip) = 5 ppmvd @ 15% O<sub>2</sub>
- Particulate Matter less than 10 Microns Diameter (PM10) = 9.5 lbs/hr

Also, Siemens confirms that natural gas with a Woobe Index of 1335-1385 will not affect Siemens ability to comply with the above limits, assuming the fuel is in compliance with Siemens fuel specification ZDX555-DC01-MBP-2500-01.

Sincerely

James W. Heller

New Generation Sales Manager

## SYSTEMS ASSESSMENT & FACILITIES SITING DIVISION

Terrence O'Brien Deputy Director

Therefore, staff's finding of no significant air quality impacts considers the fact that the project area is in attainment of the federal ambient air quality standards, the project will not cause any new exceedances of those standards, and that the ambient air quality standards are protective of human health and ecosystems.

The paragraph on page 4.1-36 was provided to answer a specific comment on sulfur dioxide impacts provided by Emerald Farms and referenced on that page. Sulfur dioxide emission concentrations in Colusa County are low in comparison with many other agricultural areas in California and much lower than in other parts of the United States that have concentrations more than an order of magnitude higher than experienced in the Sacramento Valley. The worst-case modeled 3-hour concentration from project operation is 51.1  $\mu g/m^3$  (project impact plus background from AIR QUALITY Table 23), which is well below the 1300  $\mu g/m^3$  ambient level required by the U.S.EPA secondary standard (3-hour standard of 0.5 ppm or 1300  $\mu g/m^3$ , 40 CFR Sec. 50.5). Staff stands behind the statement that these low concentrations of sulfur dioxide are not expected to cause significant crop damage.

Comment: Emerald Farms 13. The modeling analysis appears to be done improperly, an independent analyst should have been hired to review the modeling analysis, and ozone modeling should have been performed.

Response: The modeling analysis was reviewed by an independent analyst, Mr. William Walters who is a California Registered Professional Engineer, and through this review comments were made requiring significant revision to both the emission and modeling analyses. These revised modeling analyses meet all CCAPCD modeling requirements, U.S. EPA PSD modeling procedures, and were found to be completely proper by the Energy Commission's independent analyst.

Unlike other criteria pollutants, ozone will not be directly emitted by the project. Ozone is formed through a series of complex photochemical reactions involving NOx and VOC, which will be emitted by the project. Due to the complex formation mechanisms, ozone modeling is performed on a regional scale using three-dimensional photochemical grid models, whereas point source Gaussian plume models are generally used for the other directly emitted pollutants. California and federal permitting regulations do not require ozone impact analyses for stationary source permitting.

**Comment: Emerald Farms 14.** There is no discussion of the potential future use of LNG and its related impacts.

Response: The use of LNG should not significantly impact the air pollutant emissions from the power plant. First, any LNG that is added to the main PG&E pipeline providing natural gas to the CGS will be diluted by other natural gas sources. Second, the heat rate and other characteristics of received LNG will be regulated. Third, the PG&E pipeline gas will have to meet CPUC regulated composition standards. And fourth, LNG has a zero fuel sulfur content upon receipt (which is raised slightly by adding mercaptan odorants to meet federal pipeline regulation standards) so SOx emissions would be reduced. Finally, if the composition of the pipeline natural gas is impacted, within acceptable PG&E composition limitations, the project's CEMS will ensure compliance

with permit emission limits and the power plant can tune combustors to accommodate any long term changes to the natural gas heat content, if necessary. A study completed by the CEC on the impacts of LNG and heat rate variations to power plants operation and pollutant emissions can be downloaded from:

http://www.energy.ca.gov/2006publications/CEC-700-2006-001/CEC-700-2006-001.PDF

**Comment: Emerald Farms 15.** The CCAPCD, CEC and CARB had a meeting regarding the PDOC without allowing participation of Emerald Farms, an intervenor in the siting case.

Response: To perform its function effectively staff commonly meets or otherwise consults with other regulatory agencies. There is no requirement that Emerald Farms, the applicant, or other intervenors be included in such meetings, and they normally are not. CARB has not been part of any meetings with the CEC and CCAPCD.

**Comment: Emerald Farms 16.** The Delevan Compressor Station is not being adequately monitored for compliance by the CCAPCD.

**Response:** Staff cannot speak to the adequacy of the CCAPCD compliance monitoring for the Delevan Compressor Station; however, unlike the Delevan Compressor Station, the CGS project will also be monitored for ongoing compliance of the Conditions of Certification, which include the CCAPCD conditions, by the CEC.

**Comment: Emerald Farms 17.** The CCAPCD is not adequately responding to California Public Records Act requests, which indicates that the CGS will not be adequately monitored. Emerald Farms needs assurance that the power plant will not impact their organic certification.

**Response:** Public Records Acts requests to another regulatory agency are the responsibility of that agency, not the Energy Commission. As noted in above in response to Comment 16 the CGS will be monitored by both the CCAPCD and the CEC. As noted in the response to Comment 1 the power plant will not impact organic crop certification.

**Comment: Emerald Farms 18.** Regional air quality has not been adequately addressed, and additional mitigation should be required on a regional basis. A discussion of ozone formation being a regional issue was not provided.

Response: The project's emission mitigation, in the form of ERCs is a regional mitigation. Emission offsets for the ozone precursor emissions of NOx and VOC mitigate regional impacts of ozone formation. The potential for significant localized impacts are dealt with through Best Available Control Technology mitigation and remaining localized impacts are analyzed through air dispersion modeling. The dispersion modeling analysis found that the project's NOx emissions, prior to the use of offsets, did not cause significant localized air quality impacts.

## **ACRONYMS AND TERMS**

### **Acronyms**

Btu: British thermal unit (a unit of heat)

CO: Carbon Monoxide CT: Combustion Turbine

DLN: Dry Lo-NOx (A turbine combustor design that controls NOx

emissions)

HHV: Higher heating value Lbs/hr: pounds per hour

LMEC: Los Medanos Energy Center

MMBtu/hr: Million Btus per hour NOx: Nitrogen Oxides

PG&E: Pacific Gas & Electric Company

Ppm: parts per million

SCAQMD: South Coast Air Quality Management District

Scf: standard cubic foot

SCR: Selective Catalytic Reduction (a NOx control technology)

SoCalGas: Southern California Gas Company

SRI: Southern Research Institute

#### **Terms**

C6 +: Hydrocarbons with six or more carbon molecules.

Inerts: Non combustible components of natural gas (e.g. nitrogen and

carbon dioxide).

Mole percent: Composition in percent of the total number of molecules for that

given component. For gases it is the same as volume percent

composition.

SCONOx: Trademarked name for a NOx/CO control technology. SCONOx,

unlike SCR, does not use ammonia and has no ammonia slip

emissions.

Wobbe index: An index of fuel gas interchangeability. It is the higher heating value

(Btu/scf) of the gas divided by the square root of the density of the

gas (air density = 1)

#### **EXECUTIVE SUMMARY**

This study reports the testing results on emissions and performance of various electrical generating facilities in commercial operation that burned higher than normal heating value natural gas. During the second week of June 2005, a natural gas liquids extraction plant in Canada failed, which resulted in higher than normal heating value gas to travel south through the Pacific Gas and Electric Company (PG&E) pipeline system. The flow of natural gas occurred for three days, which allowed for testing and data collection to document and analyze the emissions and performance impacts on large gas turbines at the Redding, Sutter, Los Medanos, and Delta facilities.

There is a great deal of interest in the heat content of natural gas, with many studies, tests, and papers completed over the past several years regarding the effects of higher and lower heat content natural gas. Much of this work has been conducted to support efforts to develop natural gas interchangeability regulations/specifications. These efforts have included testing many residential and commercial combustion sources; however, to date little direct data from on-line large gas turbines serving the power industry have been available. This study attempts to provide data to begin filling this gap in empirical knowledge.

#### **Natural Gas Heat Content Excursion**

The natural gas in the PG&E pipeline excursion event showed an approximate 5 percent increase in heat content, from approximately 1,025 British thermal unit per standard cubic foot (Btu/scf) to 1,078 Btu/scf, and an approximate 2 percent increase in Wobbe index, from 1340 to 1369. Figure ES-1 shows the heat content data, as measured by PG&E from June 10 through June 13, 2005, in Pittsburg, California.

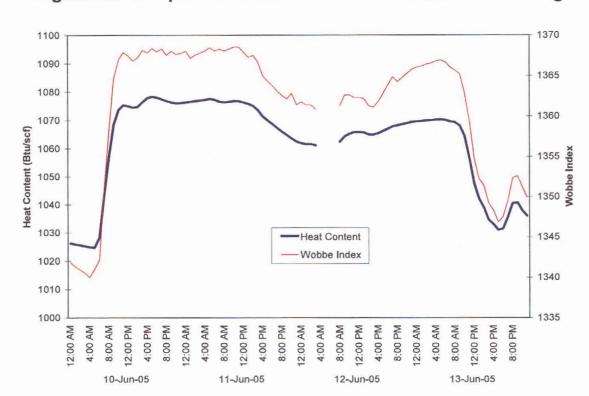

Figure ES-1: Pipeline Natural Gas Heat Content at Pittsburg

The heat content excursion varied over time, decreasing from the peak that occurred early in the excursion. The excursion lasted approximately 3.5 days at Pittsburg. The start and end time of the excursion varied based on location as the natural gas traveled from north to south through the pipeline.

A more complete description of the pipeline natural gas and as-used fuel natural gas is provided in Chapter 2.

# **Gas Turbine Operational Effects**

In general, the heat content excursion caused little or no noticeable effect in facility operations or exhaust emissions based on the available data. The only effects that could be shown statistically are minor increases in pre-control system nitrogen oxides (NOx) and NOx control system ammonia use. The post-control system NOx emissions did not show any trend versus fuel heat content or Wobbe index. Using the results from the Sutter Plant as an example, Figure ES-2 shows the Pre-Selective Catalytic Reduction (SCR) NOx (@ actual  $O_2$  levels) versus fuel Wobbe index for Sutter Combustion Turbine 2 (CT2) during high load operation.

Figure ES-2 – Sutter CT2 Pre-SCR NOx Levels versus Wobbe Index

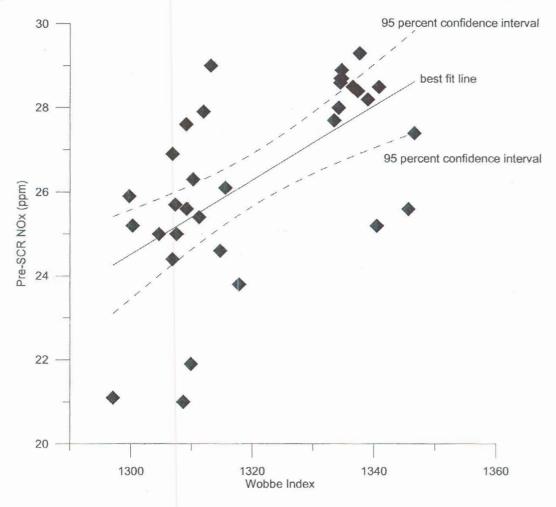

Figure ES-2 shows the best fit linear equation line with a 95 percent confidence interval for that fit. The high load interval presented in the figure is for high load hours that range in heat input from 1,700 and 1,800 million Btu per hour (MMBtu/hr). An approximate 15 percent increase in pre-SCR NOx concentration for a 3.5 percent increase in Wobbe index is predicted. Additional pre-control system NOx concentration data compared to heat content and Wobbe index are presented in Section 4.

Figure ES-3 shows the SCR system ammonia use versus natural gas heat content for the Sutter facility CT2.

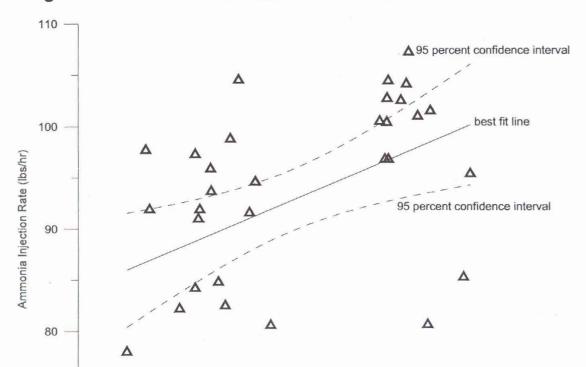

Figure ES-3: Sutter CT2 Ammonia Use versus Wobbe Index

The ammonia consumption rates during the same high turbine load interval for Sutter CT2 are shown in Figure ES-3 with a best linear fit and 95 percent confidence interval for that fit. An approximate 10 percent increase in SCR ammonia use for a 3.5 percent increase in Wobbe index is predicted.

1290

While the Sutter CT2 pre-SCR NOx emission concentrations and ammonia injection rates show a minor increase with increased Wobbe Index at high loads, the post-SCR NOx concentrations do not show any significant increase with Wobbe index. Figure ES-4 shows the post-SCR NOx levels (@15% O<sub>2</sub>) for the Sutter CT2 at the same high load interval shown in Figures ES-2 and ES-3.

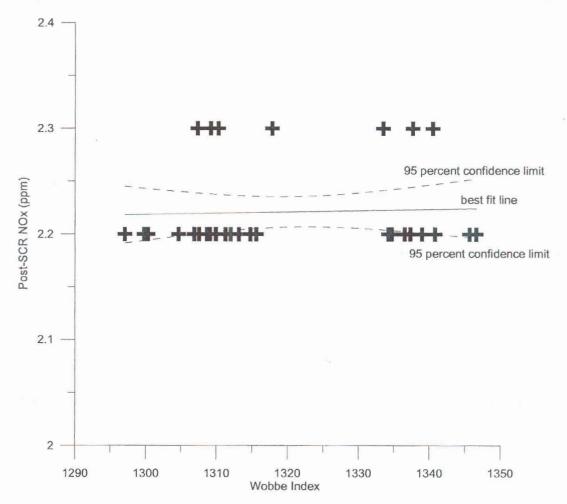

Figure ES-4: Sutter CT2 Post-SCR NOx versus Wobbe Index

Figure ES-4 includes a best linear fit and a 95 percent confidence interval for that fit. No apparent trend in controlled NOx concentrations at the higher load interval is predicted. Additional data on controlled NOx concentrations for the other facilities are provided in Section 4.

# **Summary**

The increase in heat content/Wobbe index caused a small increase in pre-SCONOx and pre-SCR NOx emissions of the Redding and Sutter facilities, respectively, and an increase in ammonia use, indicating an increase in pre-SCR NOx emissions, at the Delta and Los Medanos facilities.

At no time during normal operations did any of the controlled NOx concentrations at any of the facilities included in this study exceed their air quality permit limits. The NOx control systems for these facilities were able to adjust to counteract the increased turbine NOx emissions.

# **CHAPTER 1: INTRODUCTION**

#### **Event Introduction**

In June 2005, Pacific Gas and Electric Company (PG&E) notified the California Energy Commission (Energy Commission) that a slug of high heating value gas, resulting from an outage at a liquids extraction plant in Canada, would be moving through the PG&E system.

An increase in heating value of approximately 6 percent, from about 1,020 to about 1,080 Btu per cubic foot, lasted for approximately 3 days. Customers south of Stockton and San Jose had lower increases in the energy content of their gas.<sup>1</sup>

The Energy Commission requested both natural gas testing and gas turbine operating data, including emissions data, from several electric generating plants that used gas from the affected pipeline for several days surrounding this event. The electric generating plants that voluntarily participated include the City of Redding Generating Unit #5 (Redding),<sup>2</sup> the Sutter Power Plant (Sutter),<sup>3</sup> the Los Medanos Energy Center Los Medanos or LMEC),<sup>4</sup> and the Delta Energy Center (Delta).<sup>5</sup> The pipeline route and participating facilities are shown on Figure 1-1.

#### **Collected Event Data**

The data that were available and collected from each of the power facilities varied due to facility design and data access. A summary of the natural gas and facility operating data provided from each plant is provided in Table 1-1. The collected data are presented in Appendix A.

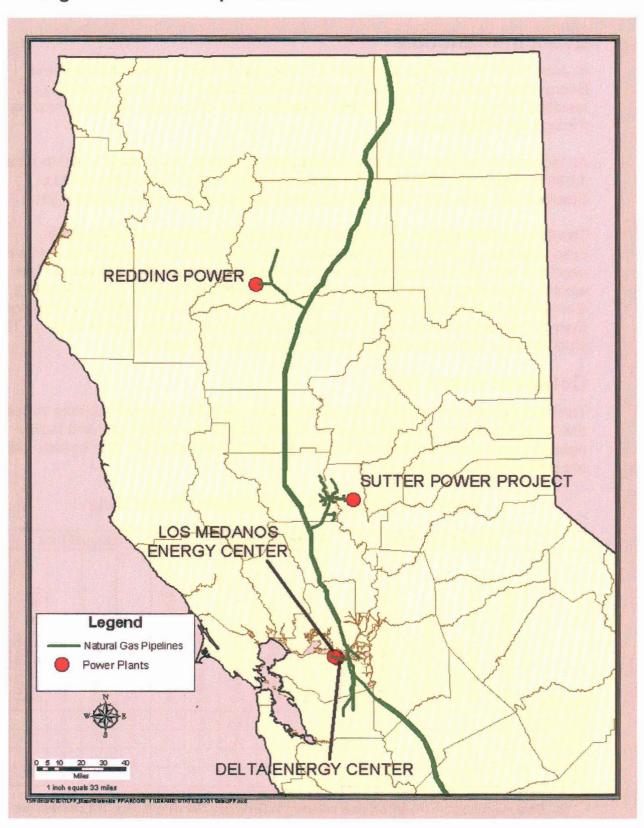

Table 1-1	I. POWER	Plant (	Callacted	<b>Event Data</b>

<sup>1 -</sup> Data supplied were limited to the as-used blended gas composition data.

<sup>2 –</sup> Data supplied from PG&E pipeline adjacent to Delta gas blending facility, but blended gas composition data for Delta were not available.

Figure 1-1: PG&E Pipeline Route and Power Plant Locations

One limitation of this study is the fact that the three Calpine facilities (Sutter, LMEC, and Delta) all used blended gas fuels, either exclusively or partially, during the excursion event. The data available for these blended gas streams, excepting Sutter, did not include enough data to calculate Wobbe index, so most of the excursion event effect comparisons use gas heat content rather than Wobbe index.

# **Study Goals**

The goals of this study were to obtain quality data for the gas heat content excursion event and corresponding gas turbine operational data during the event as well as to determine any perceived effects to the gas turbine operations due to the increased natural gas heat content. To determine operational effects, the levels of NOx emissions (as measured leaving the turbine) and controlled NOx emissions (as measured following NOx control technology) were analyzed. Ammonia injection rates were also analyzed, since ammonia is used for NOx control at three of the four facilities.

This study will support the assessment of the potential impacts of natural gas variability and natural gas interchangeability rulemaking (CPUC R.04-01-25) on the operations of large natural gas-fired power production facilities. Comments on this study will be used to help define future work necessary to adequately assess this subject.

# CHAPTER 2: NATURAL GAS EVENT DATA SUMMARY

Natural gas data were obtained both at the pipeline and for gas mixtures used at various gas turbine sites, with the exception of the Delta facility where the as-used blended fuel gas heat content and composition data were not available.

# **Pipeline Natural Gas Data**

Pipeline specific data for the natural gas excursion were monitored at two locations, Redding and Pittsburg. The Redding natural gas data are from Redding Power Unit #5, which uses the pipeline gas without blending. The Redding natural gas data are limited to Btu content. The Pittsburg natural gas data are from the PG&E Los Medanos pipeline just upstream of a blending station used for the Delta and Los Medanos facilities. The Pittsburg natural gas data include Btu content, specific gravity, and other compositional data (hydrocarbon, inerts, etc.).

Figure 2-1 presents the Redding and Pittsburg pipeline natural gas heat content data, and Pittsburg pipeline natural gas Wobbe index for June 8 through June 13, 2005. The available Pittsburg natural gas data begin June 10.

Figure 2-1: Pipeline Natural Gas Heat Content and Wobbe Index

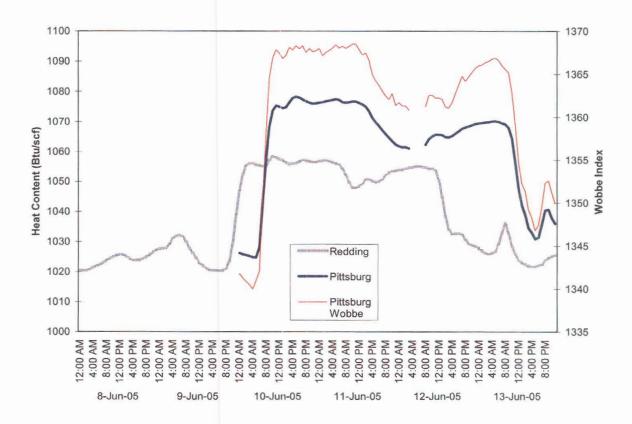

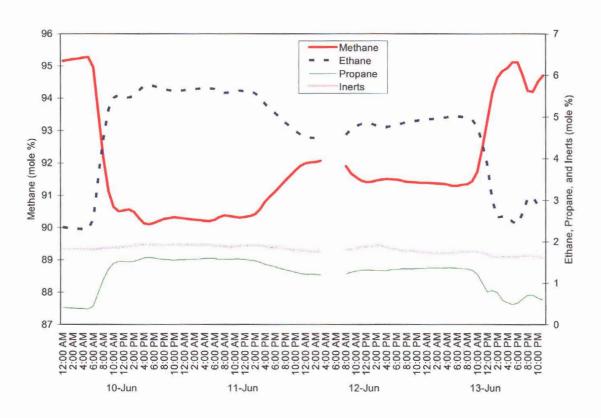

Figure 2-1 shows that the data for the excursion event at the two separate pipeline locations have a very similar shape with a time lag of several hours for the gas to

flow from Redding to Pittsburg. However, the total Btu contents and increases during the excursion event are different - both the heat content and duration of the excursion are greater at Pittsburg. The excursion event heat content and Wobbe index increase at Pittsburg was 5 percent and 2 percent, respectively, during the excursion event, while the heat content increase at Redding was a little less than 4 percent during the excursion event. There does not appear to be any reason why the duration and heat contents should be significantly different in these two locations.

Figures 2-2 and 2-3 present the Pittsburg natural gas compositional data from June 10 through June 13, 2005. For graphing purposes, the data are grouped by components with similar content levels.

Figure 2-2: Pittsburg Natural Gas Major Component Composition
Data

As would be predicted, Figure 2-2 shows that during the excursion the methane concentrations decreased by 4 to 5 percent while the ethane and propane concentrations essentially doubled. The higher heating value of the gas is the result of greater percentages of non-methane components such as ethane and propane. The inerts concentrations, which were shown to be entirely nitrogen and carbon dioxide, increased very slightly during the excursion event, with the nitrogen content decreasing and the carbon dioxide content increasing at a greater level to create the overall slight increase in total inerts.

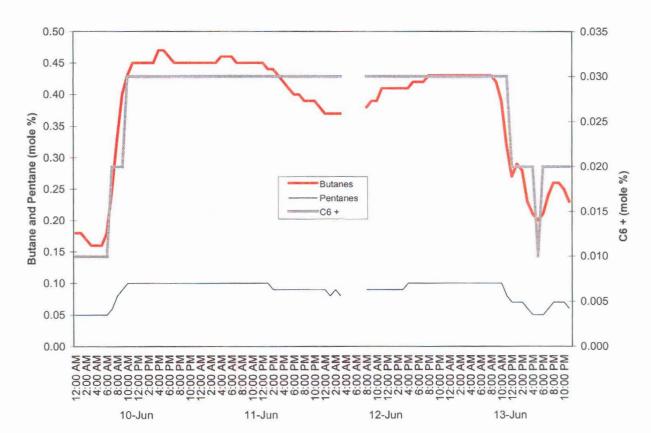

Figure 2-3: Pittsburg Natural Gas Minor Component Composition

Figure 2-3, like Figure 2-2, shows an increase in the heavier hydrocarbon composition during the heat content excursion event. The total butane (i-butane and n-butane) and total C6 + hydrocarbon concentrations (hydrocarbons with six or more carbon molecules) essentially tripled during the excursion and the total pentane (i-pentane and n-pentane) concentration doubled during the excursion.

The natural gas specific gravity measured at Pittsburg increased by a maximum of just over six percent during the excursion event.

## **Turbine Fuel Data**

The turbine fuel heat content and composition for the Sutter and Los Medanos facilities are not the same as the pipeline fuel since the as-used fuel for each is a blend of sources.

## Sutter

Figure 2-4 provides the heat content and Wobbe index data for the Sutter facility fuel during the excursion period.

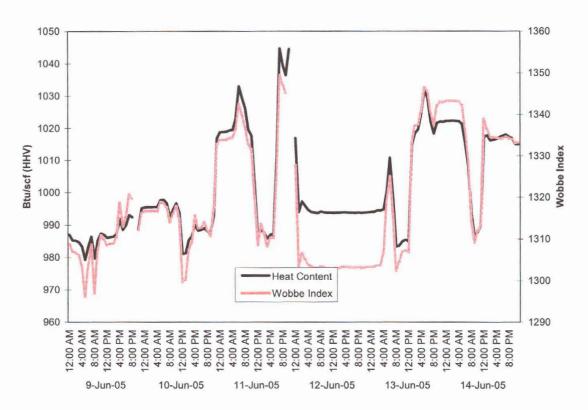

Figure 2-4 shows that the heat content and Wobbe index of the natural gas were variable during the excursion period and do not match the excursion event curve shown in Figure 2-1. The mixing of separate fuel sources allowed the Sutter facility to buffer the impact of the heat content excursion for most of the excursion period; however, the overall heat content and Wobbe index variations during short periods are as large as, or greater than, that shown for the Pittsburg pipeline gas in Figure 2-1.

Limited composition data were also available from the Sutter facility fuel gas. These are presented in Figures 2-5 and 2-6.

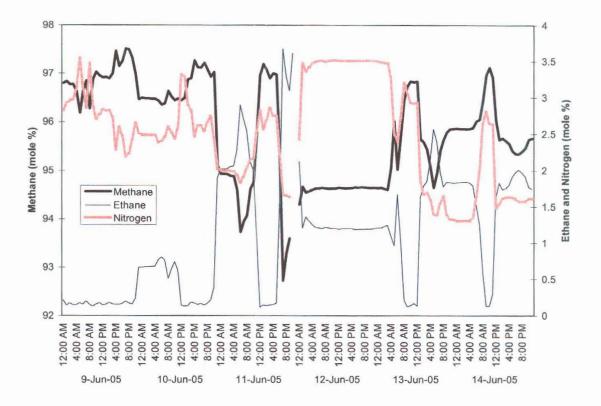

Figure 2-5 shows that the composition of the major components varied significantly during the excursion period. The variable mixture of different fuel sources created a highly variable fuel mix. The methane composition varies by almost 5 percent, the ethane composition varies from near 0 percent to over 3.5 percent, and the nitrogen content varies by nearly a factor of 3.

A critical review of the Sutter natural gas fuel data indicates that the non-pipeline fuel source being used in the blend contains an almost exclusive mixture of methane (~97 percent) and nitrogen (~3 percent) with very little ethane (~0.1 percent) and essentially no propane or butane. Using this composition assumption for the non-pipeline blend gas, Figure 2-6 shows clearly when pipeline gas with its higher propane and butane content is being used in the fuel gas blend.

0.14 0.9 Propane 0.12 Butane 0.8 0.1 0.7 Propane (mole %) (mole %) 0.6 0.08 0.5 Butane ( 0.4 0.3 0.04 0.2 0.02 0.1 12:00 AM

Figure 2-6: Sutter Natural Gas Minor Component Composition

Overall, the monitored propane and butane concentrations at Sutter are significantly lower than the pipeline concentrations monitored at Pittsburg due to the fuel bending.

12-Jun-05

14-Jun-05

13-Jun-05

# Los Medanos

9-Jun-05

10-Jun-05

Figure 2-7 shows the heat content of the natural gas used at the Los Medanos facility during the excursion event.

11-Jun-05

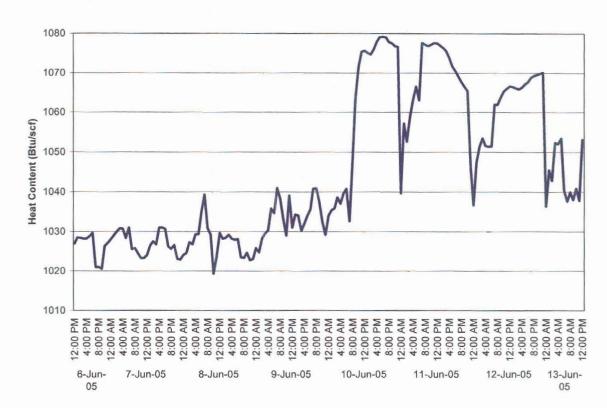

Figure 2-7: Los Medanos Natural Gas Heat Content Data

This figure matches much of the Pittsburg pipeline gas excursion curve, but due to the facility occasionally accepting the Calpine/PG&E mixed gas, as well as the unmixed pipeline gas, the curve is broken up with areas of lower Btu content. For periods of time during the excursion event, this facility consumed gas with a Btu content that was nearly 5 percent higher than the average heat content for the days prior to the excursion event.

# **Natural Gas Composition Definitions and Regulations**

The data presented above were compared to rules and regulations regarding the content of natural gas. Current relevant natural gas definitions and regulations are as follows:

- PG&E Rule 21 requires pipeline natural gas to have a heating value that is consistent with the standards established by PG&E for each Receipt Point(s), and requires gas interchangeability in accordance with the methods and limits presented in American Gas Association (AGA) Bulletin 36.<sup>6</sup>
- SoCalGas Rule 30 requires pipeline natural gas to meet lower and upper Btu limits of 970 and 1150 Btu/scf (HHV, Higher Heating Value), respectively, and to meet AGA Bulletin 36 interchangeability indices.<sup>7</sup>
- The U.S. Environmental Protection Agency (EPA), for the purposes of its New Source Performance Standard regulation for gas turbines (40 CFR Part 60 Subpart GG), defines natural gas as containing at least 70 percent by volume methane or having a Btu content of 950 to 1100 Btu (HHV).

It should be noted that PG&E Rule 21 does not include the Wobbe index in its natural gas definitions, limits, or specifications.

The natural gas in the pipeline during the excursion event remained within the higher end of the Btu limit of these definitions, and the methane content remained over 90 percent during the excursion. The Btu content of the gas stayed within the maximum allowable PG&E specification for that pipeline (1080 Btu/scf).

Additionally, the variability of the Wobbe index, as evidenced at Pittsburg, would have complied with SoCalGas Rule 30 specifications and remained well below 1400.

# **CHAPTER 3: GAS TURBINE DATA SUMMARY**

As noted previously, four facilities provided natural gas and turbine performance data. The gas turbine model and number and associated emission control technologies for each of those facilities are as follows:

**Table 3-1: Gas Turbine Description Summary** 

Facility	Turbine Type (Number)	MW (Turbine/Plant)	<b>Emission Control Technologies</b>
Redding	Alstom GTX100 (1)	43/56 (Unit 5 only)	SCONOx
Sutter	Westinghouse 501FD (2)	175/540	DLN, SCR, and Oxidation Catalyst
Delta	Westinghouse 501FD (3)	175/861	DLN, SCR
LMEC	General Electric 7FA (2)	172/555	DLN, SCR, and Oxidation Catalyst

All four facilities have NOx controls which will adjust to maintain preset NOx exhaust concentration limits. Three of the four facilities use ammonia to control NOx emissions; only the SCONOx technology, used at the Redding facility, does not use ammonia.

# Redding

The Redding facility provided natural gas heat content data, and gas turbine fuel use and certain exhaust emission parameters. As noted above, this facility does not use ammonia. The operating heat input of the gas turbine during the excursion is provided in Figure 3-1.

Figure 3-1: Redding Turbine Operating Heat Input Load Data

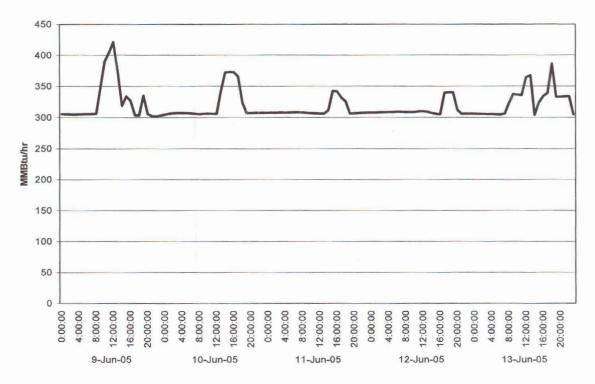

Figure 3-1 shows that the facility was running in a fairly consistent reduced load mode with daily increases in load during the afternoon. Less variable operating conditions are desired when determining the effect of the gas heat content increase on turbine operations. The more operating parameters that are static during the excursion event, the more likely that actual effects can be observed.

#### Sutter

The Sutter facility provided natural gas Btu content and composition data, gas turbine fuel use, MW production, and certain exhaust emission parameters. Ammonia is used for NOx control at this facility. The operating heat input of the two gas turbines during the excursion event is provided in Figure 3-2.

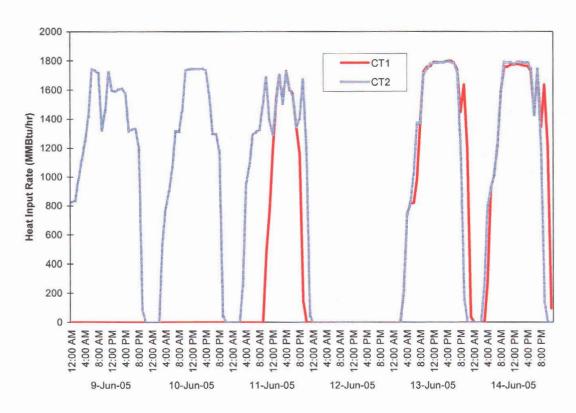

Figure 3-2: Sutter Turbines Operating Heat Input

This figure shows that the Sutter facility operations were variable during the excursion period. However, there are three times when operations were consistent for a few hours at a time (on June 10, June 13, and June 14) that may provide some useful effects data. However, the rest of the period either represents down time, startup or shutdown periods, or is otherwise considered too variable for comparative purposes.

#### Los Medanos

The LMEC facility provided natural gas heat content, gas turbine fuel use and MW output, and certain exhaust emission parameters. The facility uses ammonia for NOx control. The operating heat input of the two gas turbines during the excursion is provided in Figure 3-3.

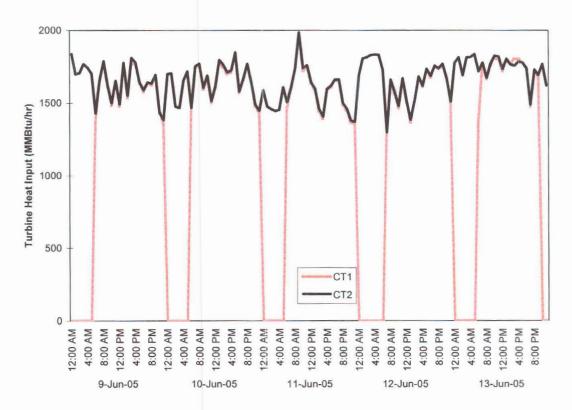

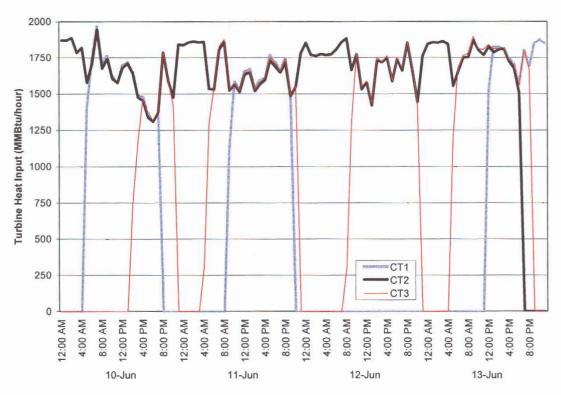

Figure 3-3: LMEC Turbine Operating Heat Input

As shown in Figure 3-3, the load input of Turbine 2 (CT2), while somewhat variable, ranged between approximately 1300 and 2000 MM Btu/hr for the entire period of the heat content excursion, while Turbine 1 (CT1) underwent many startup/shutdown cycles during the period. The major limitation for using LMEC data to determine effects of the higher Btu gas is that only controlled emissions data were available. Therefore, the ammonia injection quantities will be the main variable assessed to determine if any effects were shown during the excursion event. However, due to the hourly load variability, the normal ammonia injection rate variability may be greater than what would occur due from an increase in gas heat content/Wobbe index.

#### Delta

This facility was operating in load following mode during the period of the excursion. Similar to LMEC, the small quantity of highly variable operating data that was obtained has limited use in predicting effects from the natural gas heat content excursion. This is exacerbated by the fact that actual as-used natural gas heat content data are not available for the period of the excursion event. However, for information purposes, the operating heat input data for the three Delta turbines are presented in Figure 3-4.

Figure 3-4: Delta Turbine Operating Heat Loading and MW Output

As shown in Figure 3-4, the load is highly variable and Turbines 1 (CT1) and 3 (CT3) went through numerous startup and shutdowns during the period. Turbine 2 (CT2) operated more consistently than the other two turbines.

## **CHAPTER 4: OBSERVED EVENT EFFECTS**

The observed effects are presented facility by facility and for each turbine, if multiple turbine data are available.

# Redding

The data obtained for the Redding gas turbine included pre- and post SCONOx NOx levels. The Redding facility operated with some consistency during the excursion event period so determining the relationship between the heat content of the gas and NOx emissions is fairly straightforward. Figure 4-1 shows the pre-SCONOx NOx emissions (@ actual  $O_2$  levels), the gas turbine heat input, and the natural gas heat content for the data collection period.

1060 31 1055 30 1050 29 Pre-SCONOx NOx Emissions ( 1045 Heat Content (Btu/scf) 28 1040 1035 1030 25 1025 Natural Gas 24 1020 NOx 1015 4:00 PM 8:00 PM 4:00 PM 8:00 PM 12:00 PM 4:00 PM 2:00 PM 8:00 AM 12:00 AM 4:00 AM 4:00 PM 8:00 PM 8:00 AM AM 2:00 AM 4:00 AM 2:00 PM 4:00 AM 12:00 AM 4:00 AM 8:00 AM 12:00 PM 8:00 AM 2:00 AM PM PM PM 8:00 12:00 4:00 8:00 9-Jun-05 10-Jun-05 11-Jun-05 12-Jun-05 13-Jun-05

Figure 4-1: Redding Turbine Pre-SCONOx NOx Levels and Fuel Heat Content

As noted previously, and shown in Figure 3-1, the load increased every afternoon to handle additional demand, so the increases in NOx concentrations seen in the afternoon are at least partially due to the increase in load. By removing these peaking load periods a more definitive relationship can be established. This relationship is shown in Figure 4-2.

Figure 4-2: Redding Turbine Pre-SCONOx NOx Emissions Trend with Increased Fuel Heat Content

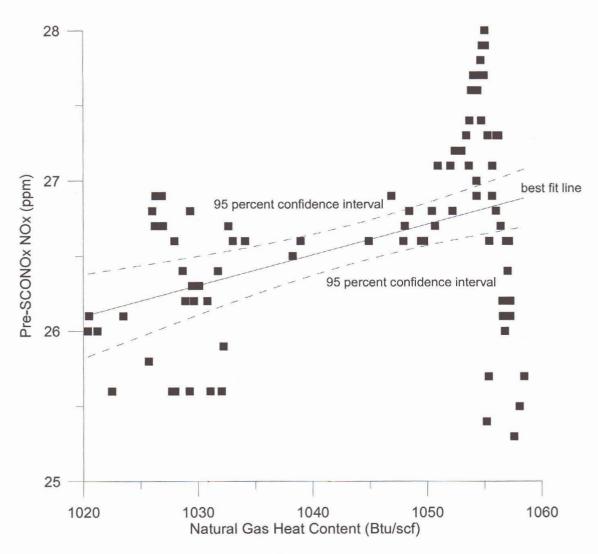

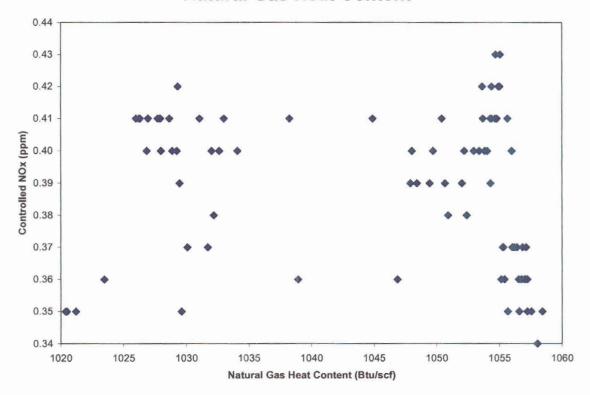

Figure 4-2 predicts that, for the range of natural gas heat contents observed, the pre-SCONOx NOx emissions will increase approximately 4 percent for a heat content increase of 4 percent. The turbine load represented by this data was limited to approximate values between 300 and 310 MMBtu/hr heat input (see Figure 3-1), which is approximately 60 percent of full load. It is possible that the effects shown in Figure 4-2 would be more pronounced at full load. Figure 4-2 also presents a linear regression best fit line and a 95 percent confidence interval for that fit.

Figure 4-3, using the same load level range as in Figure 4-2, shows that there appears to be no such pattern for the controlled NOx emissions (@15% O<sub>2</sub>). The SCONOx system appears to be able to compensate for the apparent increase in pre-SCONOx NOx emissions caused by the increase in natural gas heat content/Wobbe index.

Figure 4-3: Redding Turbine Controlled NOx Concentration versus
Natural Gas Heat Content

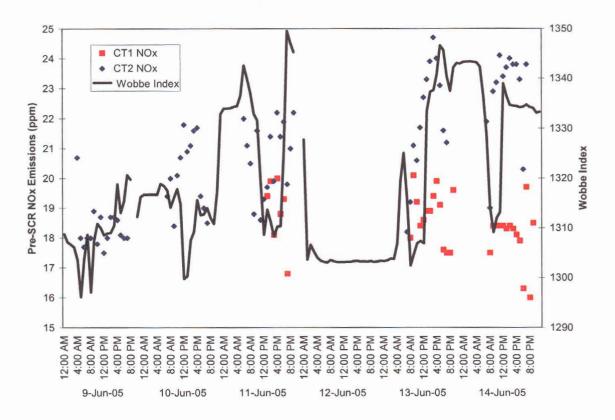

In conclusion, the increased heat content of the natural gas caused a slight increase in pre-SCONOx NOx emissions; however, the SCONOx control system was able to compensate so that the exhaust emissions did not increase by the same factor.

#### Sutter

The data obtained for the Sutter gas turbines include pre- and post-SCR NOx levels and ammonia injection rates. The Sutter facility operated for two periods of stable load during the excursion event (see Figure 3-2); data from these periods are used in the analysis. Figure 4-4 shows the pre-SCR NOx emissions (@15% O<sub>2</sub>) for normal operating hours and fuel Wobbe index during the entire data collection period.

The data in Figure 4-4 can be somewhat misleading since the data cover all normal operating data regardless of turbine load, and turbine load will clearly affect NOx emissions. By focusing on Sutter CT2 and its periods with stable loads, a more definitive relationship between pre-SCR NOx levels and fuel heat content/Wobbe index can be established. This relationship is shown in Figures 4-5 and 4-6 (NOx levels not corrected to 15% O<sub>2</sub>).

Figure 4-5: Sutter CT2 Pre-SCR NOx Levels versus
Natural Gas Heat Content

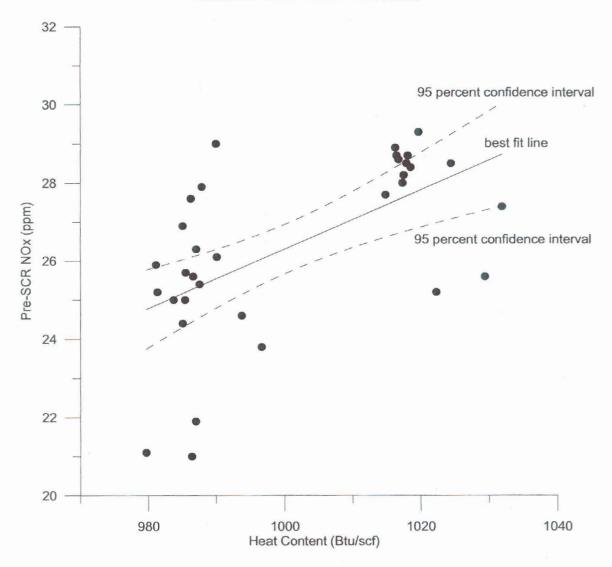

Figure 4-5 predicts that, for the range of natural gas heat contents observed, the pre-SCR NOx emissions will increase approximately 15 percent for a heat content increase of 5 percent at high turbine loads (1700 to 1800 MMBtu/hr). Figure 4-5 also presents a linear regression best fit line and 95 percent confidence interval for that fit.

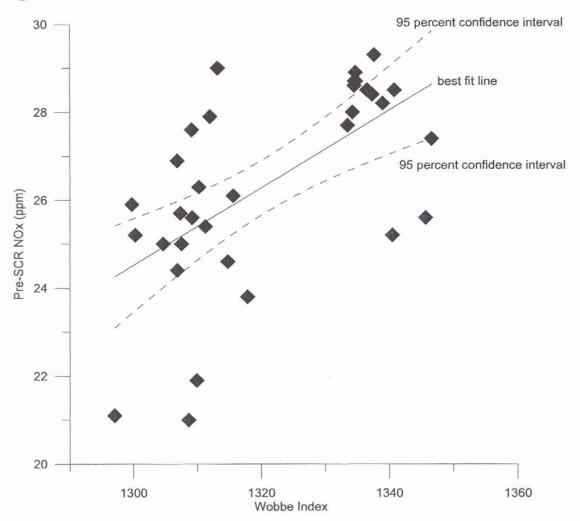

Figure 4-6 predicts that, for the range of Wobbe index observed, the pre-SCR NOx emissions will increase approximately 15 percent for a Wobbe index increase of 3.5 percent at high turbine loads (1700 to 1800 MMBtu/hr). Figure 4-6 also presents a linear regression best fit line and 95 percent confidence interval for that fit.

A similar relationship between ammonia injection and natural gas heat content/Wobbe index is shown in Figures 4-7 and 4-8.

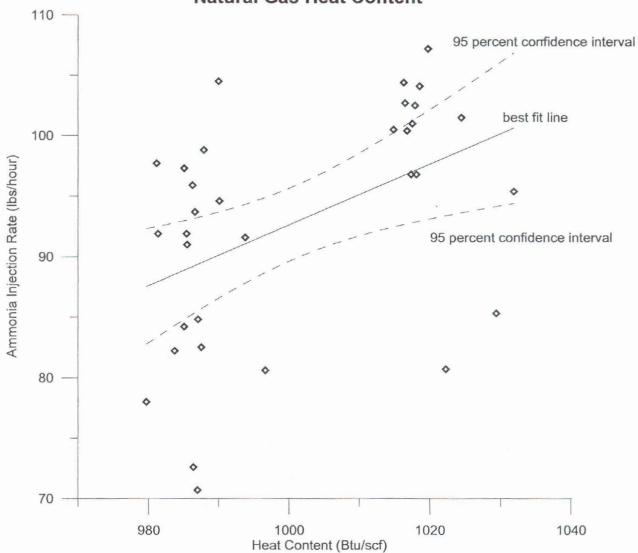

Figure 4-7 predicts that, for the range of natural gas heat contents observed, the ammonia consumption will increase approximately 10 percent for a heat content increase of 5 percent. Figure 4-7 also presents a linear regression best fit line and a 95 percent confidence interval for that fit.

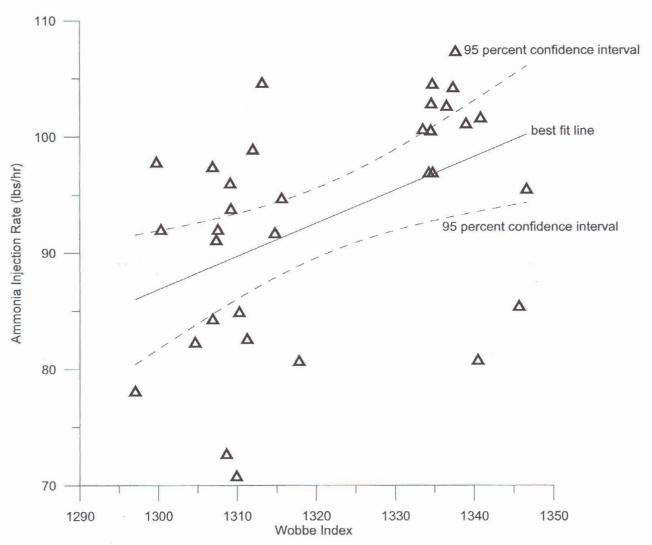

Figure 4-8 predicts that, for the range of natural gas heat contents observed, the ammonia consumption will increase approximately 10 percent for a 3.5 percent increase in Wobbe index. Figure 4-8 also presents a linear regression best fit line and a 95 percent confidence interval for that fit.

Figures 4-9 and 4-10 show that the controlled NOx emissions (@15%  $O_2$ ) do not appear to be affected by the increase in fuel heat content/Wobbe index. With the exception of one value for Turbine 1, the SCR system controlled the NOx emissions to 2.2 to 2.3 parts per million (referenced to 15 percent  $O_2$ ).

Figure 4-9: Sutter Turbines Controlled NOx Concentration versus Natural Gas Heat Content

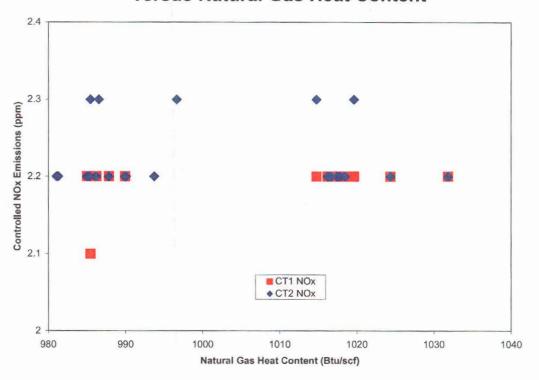

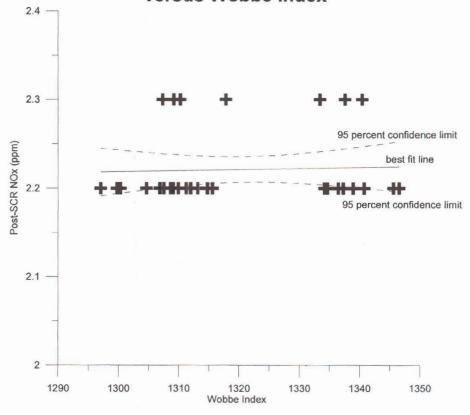

Figure 4-10: Sutter Turbines Controlled NOx Concentration versus Wobbe Index

In conclusion, the increase in natural gas heat content/Wobbe index does not significantly affect the controlled NOx concentrations at the Sutter facility but does seem to cause a small increase in pre-SCR NOx emissions and a corresponding increase in the NOx control system's ammonia consumption.

#### Los Medanos

9-Jun-05

The data obtained for LMEC did not include pre-SCR NOx emissions, so it will be more difficult to determine observable effects of the natural gas heat content excursion. This is exacerbated by the extreme load fluctuations that occurred during the period of the excursion event, and the fact that the natural gas fuel data provided for LMEC do not overlap well enough with the periods before and after the excursion event to be able to show the effects of increases in heat content/Wobbe index. Figures 4-11 through 4-13 show ammonia injection rate data and relationships and Figure 4-14 provides NOx emission concentrations during the period for both turbines. The corresponding as-fired natural gas heat content data are also shown on Figures 4-11 and 4-14. The turbine operating data shown are for normal operations excluding startup hours.

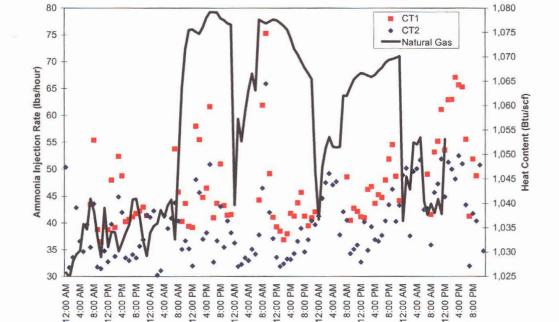

Figure 4-11: LMEC Gas Turbines Ammonia Injection Rates

Figure 4-11 shows a potential minor increase in ammonia flow versus increased natural gas heat content. This relationship has been further compared in Figure 4-12 which plots ammonia injection rates per unit heat rate versus the natural gas heat content.

11-Jun-05

10-Jun-05

12-Jun-05

13-Jun-05

Figure 4-12: LMEC Turbine Heat Load Adjusted Ammonia Injection Rate versus Fuel Heat Content

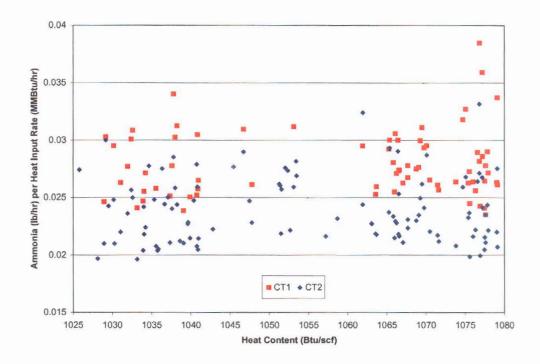

Figure 4-12 shows that there may be a small increase in the ammonia injection rate as the heat content of the natural gas increases. However, due to the operational variability, specific statistical relationships cannot be reliably determined.

In general, as shown in Figure 4-13 below, the ammonia injection rate increases with increased heat input rates. However, this relationship is much stronger for turbine heat input rates above 1700 MMBtu/hr.

Figure 4-13: LMEC Gas Turbines Ammonia Injection Rates versus Heat Input

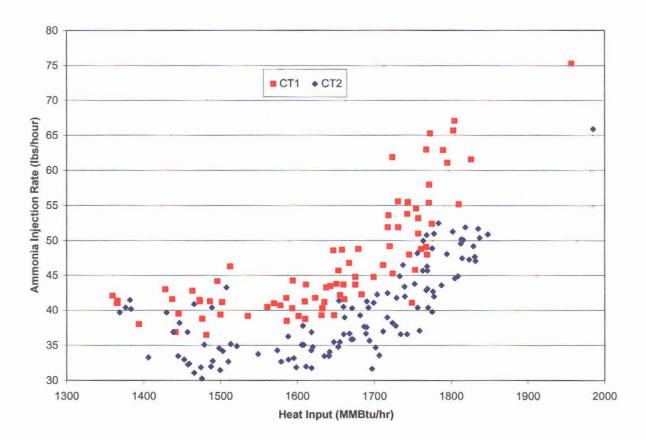

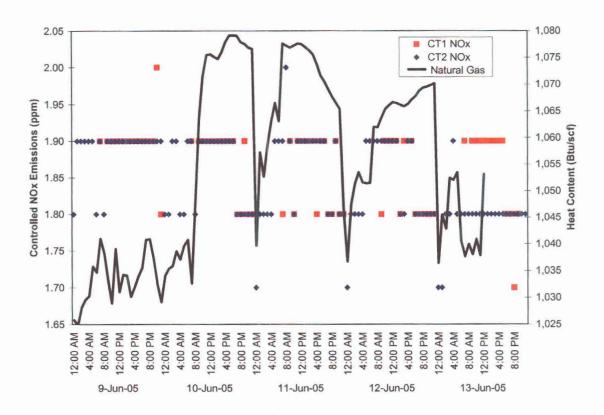

Figure 4-14, below (NOx shown @15%  $O_2$ ), shows that the NOx control system was able to compensate for probable increases in pre-SCR NOx due to the higher natural gas heat content. However, it also shows that the Turbine 2 system was slow in compensating for the three rapid decreases in heat content when Delta blended gas was fired and this caused unusually low NOx concentrations coincident with the rapid drop in natural gas heat content.

In summary, the increased heat content caused a small increase in the ammonia injection rate for the LMEC gas turbine NOx control systems, and this increase allowed controlled NOx levels to be maintained.

Figure 4-14: LMEC Turbines Controlled NOx Emissions and Natural Gas Heat Content

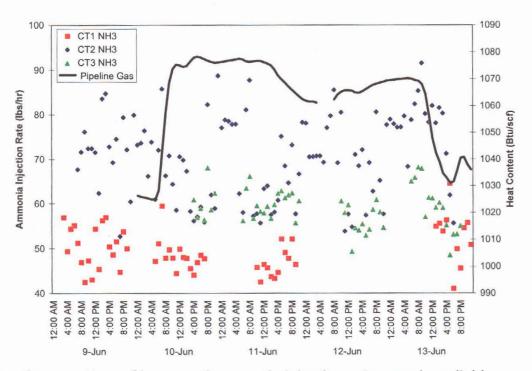

### Delta

Due to an equipment problem, the data obtained for Delta did not include as-fired natural gas heat content data. Delta uses a blended natural gas fuel, so the heat content cannot be readily predicted and therefore, the effects of the heat content excursion cannot be readily determined. Additionally, similar to LMEC, any effects on the Delta gas turbines would have been difficult to determine due to the extreme load fluctuations that occurred during the period of the excursion event, and the fact that pre-SCR NOx concentrations are not available. However, it can be reasonably assumed that the effects on the Delta gas turbines would have been minimized by the blended fuel source.

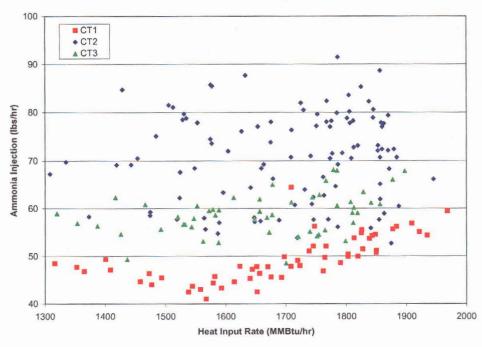

For information purposes, the ammonia injection rate over the period of the excursion event, the ammonia injection rate versus input heat rate data, and the NOx emission concentrations during the period for all three turbines are provided in Figures 4-15 through 4-17, respectively. The corresponding PG&E pipeline natural gas Wobbe index data are also shown on Figures 4-15 and 4-17 to provide an indicator when the blended fuel source would likely have experienced increases in heat content/Wobbe index. The turbine operating data shown are for normal operations excluding startup hours.

Figure 4-15: Delta Gas Turbines Ammonia Consumption

No significant pattern of increased ammonia injection rates can be reliably determined for the Delta turbines with the exception of ammonia injection versus heat input rate as shown in Figure 4-16. Figure 4-16 shows that, as expected, ammonia inject rates increase with increased turbine heat input load.

Figure 4-16: Delta Gas Turbines Ammonia Injection Rates versus Heat Input Rate

Figures 4-15 and 4-16 both show that the three Delta turbines have extremely different ammonia injection rates with Turbine 2 having rates that are on average more than 50 percent higher than Turbine 1, while Turbine 3 level ammonia injection rates fall between these two other turbines.

As can be seen in Figure 4-17, the NOx emissions (@15% O<sub>2</sub>) are very consistent during the excursion period and it appears that the NOx control system adjusted as necessary to compensate for any effects of the increased heat content/Wobbe index of the natural gas fuel.

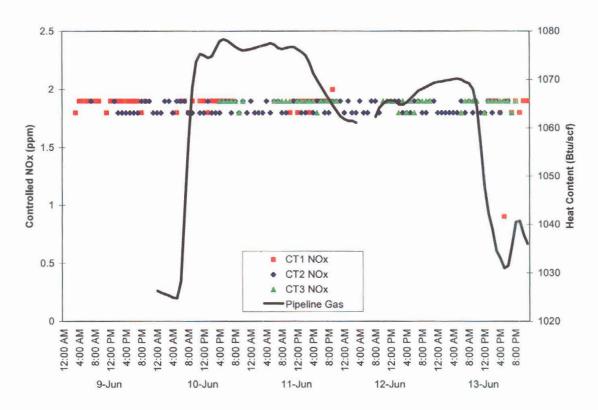

Figure 4-17: Delta Gas Turbines NOx Emissions

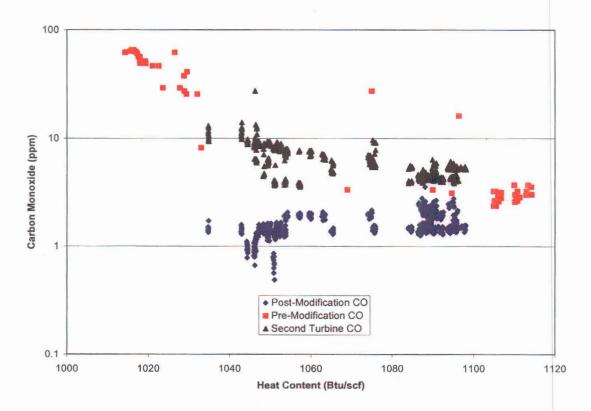

In summary, no pattern of any discernable effect of the natural gas excursion on the Delta gas turbines was discovered; however, that may be due to the amount and type of data that were available for the excursion event period.

## CHAPTER 5: OTHER VARIABLE HEAT CONTENT EFFECTS DATA

The Midway Sunset facility has provided data (not related to the above excursion event) showing the effects of a decrease in natural gas heat content on carbon monoxide emissions from GE 7001E Frame turbines. The local fuel source for the Midway Sunset facility, the Elk Hills Naval Reserve, is normally a relatively high heat content natural gas (~1100 Btu/scf). The collected data are provided in Appendix A. Figures 5-1 and 5-2 show the carbon monoxide (CO) emissions for the Midway Sunset turbine as a function of natural gas heat content and Wobbe index, respectively, before and after an expensive burner modification to allow greater fuel input flexibility. These figures also provide data for a second gas turbine that underwent additional modifications after the initial burner modification to correct the CO response issue. These turbines do not have oxidation catalysts to control the exhaust CO emissions.

For this cogeneration facility, the CO emissions concentration limit was permitted at 25 ppm. It should be noted that current permitted carbon monoxide emission limits for natural gas fired 7E turbines in the Central Valley would be expected to be around 2 to 6 ppm, and that at this regulatory level CO catalysts are generally not needed to ensure compliance during normal operations.

Figure 5-1: Midway Sunset CO Emissions versus Fuel Heat Content

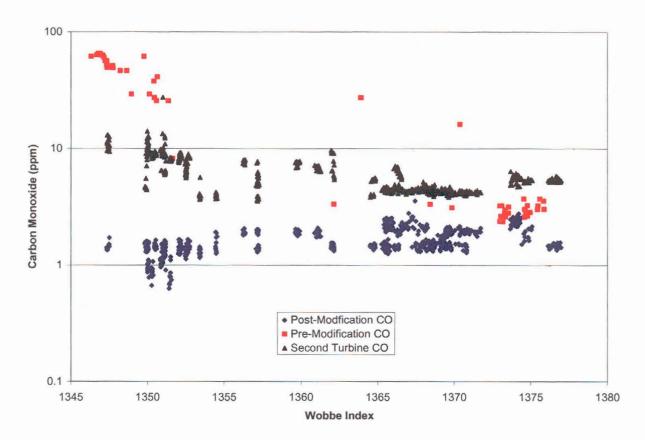

Figure 5-1: Midway Sunset CO Emissions versus Wobbe Index

The pre-modification emissions/heat content data are from May 24, 2001, and the post-modification and second turbine emissions/heat content data are from May 9, 2005.

The carbon monoxide emissions prior to the burner modification dramatically increased as fuel heat content decreased, and the second turbine shows a similar though less dramatic response with reduced fuel heat content. The dramatic response is attributed to the specific Dry Lo-NOx (DLN) burner. The Unit A turbine originally had 15 ppm NOx combustor liners, and the unit operated at 10 to 12 ppm NOx and 0 to 1.5 ppm CO with little effect with fuel Btu changes. The Midway-Sunset operator suggests, based on his experience, that combustor liners with lower NOx guarantees (that is, 9 ppm liners) have a higher sensitivity to fuel variation. The problems with significant CO emission response with Btu changes occurred after replacing the 15 ppm NOx combustor liner with a 9 ppm NOx model. It was the 9 ppm NOx combustor liner that required the additional combustor modifications to reduce CO levels to levels that complied with their permit conditions. After Midway Sunset completed the costly additional combustor modifications, the 9 ppm NOx combustor liner is now able to adjust more effectively and maintain proper combustion when the fuel heat content decreases from the normally high levels.

While the CO emissions were significantly affected due to the reduction in fuel heat content, there was a negligible effect on the Midway Sunset controlled NOx emissions. However, the Midway Sunset operator noted that, while counterintuitive due to the complexities in burner design and operation, it is possible that the NOx emissions could actually increase in certain cases when fuel heat content is reduced.

Figures 5-1 and 5-2 show that burners designed to allow a greater range in fuel composition can ensure low emissions over a wide range of natural gas fuel compositions. In fact, the post-modification burner, excepting for a few outlier data points, now results in lower carbon monoxide emissions than the pre-modified burner under all fuel heat content conditions within the range of the natural gas data provided. However, additional hot gas path component modifications, as expenenced by the second turbine, can cause the CO emission reductions gained by these burner emissions modifications to be partially negated.

## CHAPTER 6: OTHER STUDY FINDINGS/OTHER CONSIDERATIONS

## **Other Study Findings**

Other studies performed by Southern California Gas Company (SoCalGas) and the South Coast Air Quality Management District (SCAQMD), among others, have looked at the effects of increasing natural gas heat content. The principal focus of all of these studies was to determine the effect of increased heat content on NOx emissions. A short summary of the findings of these other studies is provided in Table 6-1.

**Table 6-1: Other Natural Gas Heat Content Study Finding Summary** 

Study Source	Equipment	Summary of Findings
SCAQMD	Microturbine	NOx increases with heat content increase (20 percent increase when
		Btu increases from 1020 to 1140 Btu/scf)
SCAQMD	Commercial Boiler	NOx increases with heat content increase (Max increase 17 percent)
SRI	Lean Burn Engine	Significant NOx increase with heat content increase (more than doubled
	_	for engine without air-to-fuel ratio controller, and 35 percent increase
		with controller)
SoCalGas	Residential furnaces	Little or no increase in NOx concentration with increased heat content
SoCalGas	Residential water heaters	Little or no increase in NOx concentration with increased heat content
SoCalGas	Natural Draft Burners	Little or no increase in NOx concentration with increased heat content
SoCalGas	Charbroiler	NOx increases with heat content increase (Max increase 41 percent)
SoCalGas	Deep Fat Fryer	NOx increases with heat content increase (Max increase 38 percent)
SoCalGas	Instant Water Heater	NOx increases with heat content increase (Max increase 15 percent)
SoCalGas	Pool Heater	NOx increases with heat content increase (Max increase 61 percent)
SoCalGas	Condensing Hot Water Boiler	NOx increases with heat content increase (Max increase 143 percent)
SoCalGas	Lo-NOx Hot Water Boiler	NOx increases with heat content increase (Max increase 169 percent)
SoCalGas	Lo-NOx Steam Boiler	NOx increases with heat content increase (Max increase 134 percent)
SoCalGas	Ultra Lo-NOx Steam Boiler	NOx increases with heat content increase (Max increase 50 percent)

Source: SCAQMD<sup>10</sup>

SCAQMD - South Coast Air Quality Management District

SRI - Southern Research Institute

The increased NOx values observed in many of these other tests were higher than observed at the large gas turbines in this study; however, the range of natural gas heat content in the other studies was also greater. A general conclusion that can be made from these other studies is that smaller external combustion burners that do not have high flame or combustion zone temperatures are less affected by heat content or Wobbe index than those burners that do have higher flame or combustion zone temperatures. Also, it can be generally concluded, using the former tests and the information from this report, that turbine type internal combustion engines are less affected by heat content/Wobbe index than piston type internal combustion engines. Considering the time and temperature requirements for the formation of thermal NOx, this finding is not surprising, but it is interesting that significant increases in NOx formation were found for some small external fired sources (pool heaters, charbroilers, and deep fat fryers, see Table 6-1).

It is important to note that these other studies are based on controlled tests. It is unlikely that there would be a cost effective way to perform such controlled tests with actual real-world operating power turbines and other large gas-fired power production facilities, since the amount of fuel necessary to perform such an experiment would be problematic to handle and transport, and it would be difficult for power plant operators to control operations to meet the objectives of such a controlled test.

### **CHAPTER 7: DATA LIMITATIONS**

The analyses and conclusions presented in this report are limited by the available data and the context under which the data were gathered. This study is not purported to be a controlled experiment, nor is it meant to provide conclusive findings on the impacts of natural gas heat content on all large gas turbines for natural gas quality policy or regulatory determinations. Rather, this study is meant to provide initial data and findings regarding the effects of a single natural gas Btu content excursion event.

Since this was not a controlled experiment, both the gas Btu content and turbine operations were variable during the June 10 through June 13 excursion period. Additionally, not all desired data were available from all of the facilities included in this study. In the case of the Delta Energy Center, the heat content of the fuel used was not available so the operational/emissions data could not be meaningfully processed. In other cases, such as Sutter and Los Medanos, only short periods representing a few hours over the three-day period were considered to be useful or comparable for the determination of the effects of the heat content excursion. Therefore, the quality of the data are somewhat compromised based on the short-term nature of the event and the operational variability encountered at the facilities providing data.

No direct emission comparison can be made between separate facility gas turbines, both within the same facility or in another facility. The turbine and emission control technologies designs, including the combustor liner designs, are not all consistent between the facilities included in this study, the operations of each facility are variable from one another, and each gas turbine unit in each facility undergoes physically separate tuning events at different intervals. Therefore, the specific effects of the heat content excursion are analyzed separately for each turbine. However, observations of the general trends between comparable turbines have been provided.

## **CHAPTER 8: CONCLUSIONS**

The gas turbine data collected indicate that the 2 percent to 5 percent increase in natural gas heat content observed at the facilities studied during the excursion event caused a minor increase in pre-SCONOx/SCR NOx emissions and ammonia consumption rates for facilities with SCR NOx controls. However, the controlled NOx emissions did not show such a trend, so it appears that the NOx controls (both SCR and SCONOx) were able to compensate under the range of natural gas compositions encountered during the excursion event.

The amount of data, number of facilities, types of facilities, and emission controls covered by this study were extremely limited and only represent a small fraction of the total natural gas power production facilities within California. Currently, the majority of natural gas-fired power plant emissions in California come from cogeneration and boiler facilities. Therefore, it is recommended that data from additional facilities (boilers, simple cycle turbines, cogeneration facilities, etc.) be gathered to determine if the effects observed during this study are representative of the facility types included in the study, if similar effects would occur for other technologies and emission controls, and if these effects could cause cumulatively significant impacts in exhaust emission levels.

It is recommended that natural gas data collected have sufficient information (specific gravity or full composition data) to enable the calculation of the Wobbe index. It is desirable to establish relationships between fuel Wobbe index and emissions and other operation variables in order to help guide future natural gas policy decisions.

It is also recommended that effects on fuel efficiency and greenhouse gas emissions from higher heat content natural gases also be included as future study objectives.

# Appendix A - Data Notes

## Conservat Nation

- 1. The raw data aboun are as presided to the Energy Commission. The caly manipulation was convention into speculatives formet and housy averages when other three formes were presided.
  - 2. Calculated values, such as fuel Webbs index, are shown in red.
- 3. Date not provided or missing are left blank, while date provided as TAX or in other einiter fermats, were left in those formats

# Suffer Terbine Data Mate

- 1. Suffer has two turbines
- Suffer steam augmentation data was provided; however, no steam augmentation were performed for either technic during the data position to the are not presented.
   Suffer duct thing data is only provided for CTI. CT2 had no duct fifting during the parted.

## Part Fast Date Nation

1. Softer uses a raised fuel source: the PGAE pipeline gas and Capina-curred gas that has for the content.

- 1. Redding uses feet dready from the PG&E pipuline.
- provided for Reidding starts an Jone Ob for the natural gas date, and Jone Oh for the Lattine operation date.
  - 3. The Redding fuel heat content date were converted into an hourly everage value.

- 1. Los Medenos has tao turbines
- Les Madenes can une a miner foul source: the PGRE pipelina gas and Calpino omned gas that is mined at the Data facility.
   The data provided for Los Meximos start had vary braugh Jane 6th for the natural gas data, and Jane 6th for the turbles operation data.
   The Los Madenes turbles 1891, turbles extremel temperature, and turbles hant rate data; were convented table an hourly average values.

## Delta Data Yotas

- 1. Oats has two technes
- Code uses a mixed fuel source; however, the data for the se-used fuel were not available daring the surge event.
- 3. The Dath CT2 tables BM, tables entituet imperators, and bother heat rate date were converted into an Insuly annuge values. Sigher date for CT1 and CT3 were not provided.

# Delta PG&E Natural Gas Data Motos

1. These data are for the pipuline natural gas and do not correspond to the Data larkine fast.

# Michaey Sumest Data Notes

- . The data presented are for two different time periods, and the second time period has data from the harbinas. These data are not for the POLIS species event covered by the other data.
  - 2. The Wobbe index values are calculated
- Unit A combustor was medified between the first and second paried, as was the Unit X combustor, the Unit X combustor and additional modifications pari

a. Not applicable, because startup/shutdown emissions are included in the modeling for annual average.

b. Not applicable, because emissions are not elevated above normal operation levels during startups/shutdowns.

c. Not applicable, because inversion breakup is a short-term phenomenon and as such is evaluated only for short-term averaging periods.

d. Not applicable, because engine will not operate during CTG startups/shutdowns.

e. Not applicable, this type of modeling is not performed for small combustion sources with relatively short stacks.

f. Impacts are the same as shown for CTGs.

TABLE 5.1-28 (REVISED 12/06/07)

Summary of Potential Health Risks

RECEPTOR	CARCINOGE NIC RISK <sup>A</sup> (PER MILLION)	CANCER BURDEN	ACUTE HEALTH HAZARD INDEX	CHRONIC HEALTH HAZARD INDEX
Maximum Incremental Cancer Risk (MICR) at PMI	<del>0.16</del> <u>0.15</u>		<del>0.10</del> <u><b>0.09</b></u>	<del>0.005</del> <u><b>0.004</b></u>
MEIR	0.075 0.079	0 -	<del>0.057</del> <u>0.056</u>	0.0021 0.0022
Maximally Exposed Individual Worker b (MEIW)	<del>0.080</del> <u>0.079</u>		0.030	Not applicable
Significance Level	10	1.0	1.0	1.0

### Notes:

- Derived (Adjusted) Method used by San Diego Air Pollution Control District to determine compliance with Regulation 1200.
- <sup>b</sup> The worker is assumed to be exposed at the work location 8 hours per day, instead of 24, 245 days per year, instead of 365, and for 40 years, instead of 70. Hence, a 70 year-based chronic HHI is not applicable to a worker.

## ATTACHMENT 7 REVISED MODELING README FILE

Carlsbad Energy Center Project (Encina) Modeling Files Sierra Research - Marc P. Valdez - December 13, 2007.

Six zipped files, enclosing modeling using three years of Camp Pendleton, CA meteorological data (2003 - 2005), together with corresponding hourly ozone concentration data for Oceanside. The original data was provided by the SDAPCD.

Template files originally developed within Lakes Environmental software, using standard Lakes naming conventions. Changes were subsequently made to these files in standard text editors. For example, for multiple pollutants, the input information for the first pollutant would be copied in a text editor to facilitate inputting the information needed for the other pollutants.

AERMET Output Met Data (6 files) to be used as AERMOD input files.

```
CMP_03.SFC AERMOD 2003 Surface File CMP_03.PFL AERMOD 2003 Profile File CMP_04.SFC AERMOD 2004 Surface File CMP_04.PFL AERMOD 2004 Profile File CMP_05.SFC AERMOD 2005 Surface File CMP_05.PFL AERMOD 2005 Profile File
```

ISCST3 Input Met Data (3 Files)

CMP\_03.MET ISCST3 2003 Met File CMP\_04.MET ISCST3 2004 Met File CMP\_05.MET ISCST3 2005 Met File

Ozone Data (3 Files) formatted for AERMOD input.

O3FIL03.PRN Hourly 2003 Ozone Data for Oceanside
O3FIL04.PRN Hourly 2004 Ozone Data for Oceanside
O3FIL05.PRN Hourly 2005 Ozone Data for Oceanside

Ozone Data (3 Files) formatted for ISCST3 input.

O3FIL03.ASC Hourly 2003 Ozone Data for Oceanside O3FIL04.ASC Hourly 2004 Ozone Data for Oceanside O3FIL05.ASC Hourly 2005 Ozone Data for Oceanside

FUMIGATION Files (2 files)

ENCNS01.OUT SCREEN3 Output for Turbines 1 & 2 FUMIGATION1.XLS Fumigation Calculation Spreadsheet for results presented in AFC Air Quality Section 5.1 text and appendix.

Three zipped folders for 2003, 2004 and 2005, respectively, each containing a set of 36 modeling files equivalent to the 2003 set listed here.

Standard Lakes naming convention

- \*.ADI AERMOD input file \*.OUT - AERMOD output file
- \*.ROU various receptor grids

AERMOD Files (36 files)

File Name Description

ENCN0301.ADI Turbine SCREENING, AERMOD Input File, unit impacts For different operating MODE

BPIP FILES AND DEM DATA (NAD27 DATUM)
Eight DEM files (DEM.ZIP) for the following quadrangles:

SNMARCOS.DEM SLUISREY.DEM BONSALL.DEM ENCINITAS.DEM LAPULGS.DEM MORROHIL.DEM OCEANSIDE.DEM RSANTAFE.DEM

Three BPIP Files

ENC1\_WTIER5.SUP Summary Output File

ENC1\_WTIER5.PRO Output File

ENC1\_WTIER5.BPI BPIP Input File
