 METHANE EMISSIONS FROM CALIFORNIA'S
 NATURAL GAS SYSTEM: CHALLENGES AND SOLUTIONS

CAL/EPA HEADQUARTERS BUILDING

1 001 I STREET

BYRON SHER/SIERRA HEARING ROOM

SACRAMENTO, CALIFORNIA

TUESDAY, JUNE 7, 2016

9:00 A.M.

Reported By:
 Kent Odell

APPEARANCES

Joint Agency Participants

Carolyn Lozo, California Air Resources Board
Kathleen Kozawa, California Air Resources Board
Elizabeth Scheehle, California Air Resources Board
Luis Leyva, California Air Resources Board
Laurie ten Hope, California Energy Commission
Yu Hou, California Energy Commission

Panel Presenters (* Via telephone and/or WebEx)

Session 4

Martin Kurtovich, California Public Utilities Commission
(Panel Moderator)
Tim O'Connor, Environmental Defense Fund
Robert Smith, U. S. Department of Transportation Pipeline
and Hazardous Materials Safety Administration (PHMSA)
Cynthia Powell, National Energy Technology Laboratories
Keith Driver, Cap-Op Energy
San Gunawardana, Enview, Inc.

Session 5

Regulatory Panel:

Floyd Vergara, California Air Resources Board (Panel
Moderator)
Elizabeth Scheehle, California Air Resources Board
Arthur O'Donnell, California Public Utilities Commission
Trina Martynowicz, USEPA Region 9
Brady Van Engelen, Division of Oil, Gas and Geothermal
Resources, (DOGGR) Department of Conservation
Laurie ten Hope, California Energy Commission

Stakeholders Panel:

Arthur O'Donnell, California Public Utilities Commission
(Panel Moderator)
Deanna Haines, Sempra Utilities
Briana Mordick, NRDC
Christine Cowser, PE, PG&E
John Shears, The Center for Energy Efficiency and Renewable
Technologies, CEERT

APPEARANCES (Cont.)

Public Speakers (* Via telephone and/or WebEx)

Yousheng Zeng, PhD, PE, Providence

McKinley Addy, AdTra Inc.

Jack Kitowski, California Air Resources Board

Steven Sander, CalRecycle

Daisy Pistey-Lyhne, PSE Healthy Energy

Steve Fleishman, Wolfe Research, LLC

Christopher Clavin, TSS Consultants

James Bradbury, U.S. Department of Energy, DOE

Win Setiawan, California Air Resources Board

9:02 A.M.

SACRAMENTO, CALIFORNIA, TUESDAY, JUNE 7, 2016

MS. LOZO: Good morning, everyone. Welcome to Day 2 of our Symposium, Methane Emissions from California's Natural Gas System: Challenges and Solutions. I think yesterday we heard a lot of very informative discussion. I hope you think so too. And we're all looking forward to having you all engage in the discussion further today.

Okay, just a few reminders before we get started. This is a jointly-hosted symposium by the Air Resources Board, the California Energy Commission and the Public Utilities Commission.

It is also serving as one of CEC's IEPR workshops, so as a result of that we are recording today. And please note if you would like to submit some public comment for the CEC's IEPR workshop process there's going to be a period of time at the end of the day for those public comments. And if you would like to do that there's some blue cards at the back of the room, if you could please fill out a blue card sometime today.

The restrooms again are out the back of the auditorium to the left down the hallway. There's also a water fountain out that direction. We have some water and coffee available for you in the alcove to the right outside

1 the auditorium. The cafe downstairs is also open till 3:30
2 today.

3 Also if the fire alarm sounds please go down the
4 stairs out the front entrance, the main entrance, and then
5 across the street to Cesar Chavez Park.

6 We will be posting all of the slides from both
7 days of the symposium later on this week, so look on our
8 website and look forward to those later this week.

9 Also this afternoon we'll be having a couple of
10 policy panel discussions. If you would like to submit a
11 question for one of those policy panels please write it
12 down; either write it down on the white sheets that are at
13 the back of the room at the table and submit it or go ahead
14 and ask your question during the policy panel.

15 Oh, also we have a court reporter today. If you
16 would like to make a comment or ask a question anytime
17 today it's helpful to him if you can drop your business
18 card by, so he knows who you are. It makes his job a
19 little easier.

20 All right, I think we're ready to get started
21 with Session 4. Big Gas, Big Data, and Methane: Building a
22 Monitoring, Verification and Performance Management System
23 to Meet Our Climate Change Goals. And I'd like to
24 introduce Marty Kurtovich from the CPUC.

25 MR. KURTOVICH: Thank you.

1 Good morning, my name's Marty Kurtovich with the
2 California Public Utilities Commission, we've been looking
3 forward to this session for a long time. If you were here
4 yesterday our Executive Director Tim Sullivan spoke about a
5 current proceeding we're doing, SB 1371, in developing a
6 methane-leak detection program to monitor and control
7 methane emissions from midstream and downstream of the
8 natural gas infrastructure in California.

9 And that's somewhat of a challenge for us,
10 because we previously had a leak detection and repair
11 program that was solely focused on occupational and public
12 safety rather than on climate change or monitoring direct
13 emissions. And the other challenge has been that that
14 program is decades old and was created prior to the
15 Internet and the digital tools that we just spoke
16 extensively about yesterday.

17 So part of the challenge with that proceeding,
18 and the working group that is involved in that, has been in
19 how to best utilize today's technologies and science to
20 create a regulatory framework that will meet the goals of
21 that law.

22 So we're going to get started this morning with
23 Tim O'Connor from Environmental Defense Fund. Tim is a
24 Senior Attorney and Director at EDF in California. Since
25 joining EDF in 2007, he has been engaged in state

1 regulatory agencies in the Legislature on passage and
2 implementation of climate and clean energy initiatives,
3 with particular focus on natural gas and oil issues, market
4 base emission reduction programs, transportation fuels and
5 vehicles, clean energy and conservation.

6 During this time Tim has also managed EDF's
7 participation in both state and federal courts on issues
8 related to climate change, fuels and energy. And he
9 further manages and participates in EDF's work before the
10 CPUC and the CEC on issues related to natural gas utility
11 rate setting, electric vehicles, and a whole host of other
12 issues. So please welcome Tim O'Connor.

13 MR. O'CONNOR: Thanks Marty and good morning.

14 If there's one theme of the discussion that I'd
15 like for folks to take away from the next 20 or so minutes
16 it's the theme of risk, the theme of reducing risk
17 associated with a whole host of factors whether it's
18 climate risk or safety risk, investment risk, financial
19 risk, legal risk, risk reduction, risk management. And
20 what data can do for that process is really quite an
21 important exercise to engage in.

22 And when we look at methane and what its impact
23 on our climate and planetary system is we see that the
24 science, of course, is becoming quite clear that methane is
25 responsible for nearly 25 percent of the warming that we're

1 seeing right now with emissions estimated at \$30 billion in
2 natural gas loss every year.

3 A report that we did with the Rhodium Group tries
4 to quantify those global emissions and puts the total
5 amount at about the gas production for the country of
6 Norway, which is lost into the atmosphere every single
7 year.

8 And Ramon Alvarez spoke a little bit yesterday
9 about what this actually means to California when we think
10 about the fact that we use so much natural gas. And this
11 was sort of the first time some of these numbers have been
12 presented in public.

13 This is a slide that Ramon gave yesterday, I
14 thought it was worth repeating, is that when you look at
15 all of the gas that California imports at a roughly 2.4
16 percent leakage rate on a 20-year time horizon that equals
17 about 60 million metric tons of carbon dioxide-equivalent
18 pollution. Or really, a shadow of a carbon footprint that
19 California hasn't really paid attention to associated with
20 the emissions equal to about 18 coal fire power plants.

21 And so what does all this methane data mean? The
22 fact that we know how much is coming out globally, the fact
23 that we know that it's contributing to climate change, the
24 fact that we know that California has got a big footprint,
25 well it has implications for a number of entities.

1 And the focus of risk is really where I like to
2 put it. And this risk isn't just something that we're
3 trying to minimize as we implement SB 705 here in
4 California to reduce the chance of pipeline accidents from
5 causing fatalities and safety issues. It's not necessarily
6 just the risk that we try to confront when we helped to
7 write and then pass SB 1371 on the climate side. And it's
8 not just the type of risk that we would try to characterize
9 when we helped to pass AB 1257 several years ago, looking
10 at the life-cycle carbon footprint. This is risk sort of
11 across the board: financial, reputational, regulatory,
12 environmental, leakage risk.

13 And there's really no better way to look at this
14 risk probably than looking at the repetitive set of
15 comments, letters, filings from institutional investors
16 across the planet. Starting back in June of 2012 we saw
17 roughly \$20 trillion worth of assets being represented to
18 talk about the importance of reducing methane pollution.

19 And as we see this drumbeat continue we see
20 global investors, U.S. based investors -- this October 2014
21 report or letter was written and spearheaded by the head of
22 CalPERS and CalSTRS -- and as we see this drumbeat continue
23 we see support for U.S. action, we see support for Canadian
24 action and global action.

25 And some of the important statements coming back

1 from earlier this year show that these pledges, these 40 to
2 45 percent reduction pledges, are not just because it's
3 good for the planet, because it's about minimizing risk,
4 minimizing methane emissions in a transparent manner, and
5 providing investors and the public with better methane
6 reporting. So it's like not just the "why it's important,"
7 but what to do with it.

8 And I think that some of the reasons of course,
9 the reputational side of it, the asset loss side, we also
10 see that there's a climate risk that's driving a lot of
11 this with of course Co2 emissions ever-increasing, with
12 global temperatures increasing, with actually this year in
13 February, in March, in April, in May all beating climate
14 records and surpassing the records for the highest jump
15 from month over month.

16 And we see risks associated with world heritage
17 sites. We see the Galapagos Islands being threatened in
18 terms of changing food patterns and weather patterns. We
19 see things such as the western forests and wildfire
20 increases. And there's just no limit to the amount of risk
21 that a climate change causes.

22 And in California actually, this is not just as a
23 problem with our forests being threatened from pine bark
24 beetles or we don't see this just as a problem with
25 drought, we see actually that there's a potential legal

1 issue here for Californians to not address some of these
2 issues. California to not pay to attention to what happens
3 in Texas actually opens the state up to a legal risk.
4 Indeed, AB 32 itself says there is a legal requirement to
5 minimize leakage. And leakage in the definition is an
6 emission outside of the state, which has the potential to
7 undermine activities in California.

8 And of course, over many years we have become
9 very dependent on natural gas for our power system. We're
10 using it as the new fuel source to reduce life-cycle
11 emissions from the whole fueling system. And as we benefit
12 from that use we see leakage of methane, that 60-million
13 metric tons worth of methane or the Co2 equivalent,
14 undermining the benefit that California has. And indeed we
15 think this opens California up to a legal risk for not
16 addressing imported natural gas and the upstream emissions
17 associated with it.

18 So what happens in Texas as they say doesn't
19 always just stay in Texas. It has a real impact here.

20 And as we look at where the risk lies we see that
21 new data and new tools for accumulating data help us to
22 sort of unpack what that risk is and address it. Starting
23 with everybody's favorite topic when you go to a methane
24 symposium, Aliso Canyon, showed how new data and new data
25 collection analysis actually can help with event

1 characterization and help in community and environmental
2 protection.

3 We saw a massive sampling of the air in this
4 local community during the release, making Porter Ranch
5 probably the most monitored spot on the planet during those
6 112 days earlier this year.

7 We've seen the testing of new technology and new
8 models after the release and new tools to embed that within
9 the state's inventory.

10 And indeed we even see the data coming out of
11 this actually moving regulatory efforts, moving regulatory
12 filings in fact, because the Public Utilities Commission
13 shortly after the close of the leak requested
14 quantification of major pollution events within the SB 1371
15 implementation framework. And indeed there were some
16 filings there. And here's some quotes from on the filings,
17 it said, "There are no tools to actually quantify
18 accurately the amount of emissions coming out of a major
19 pollution event, such as this nature."

20 And then just three months later we see sort of a
21 recanting of that statement by not only, of course, the
22 company that was responsible for the leak but within an
23 independently verified framework that looked at the prior
24 estimates that were conducted by the state and that were
25 published in peer review literature, such that I do think

1 that there is a way that we can see these new data tools
2 for risk management starting to come out for the purposes
3 of quantifying and understanding the impact on the climate
4 of an event of this nature.

5 And of course we have increasing utilization of
6 data from mobile monitoring equipment, which is out there
7 not just to find a leak and to try to direct a utility to
8 go zero down and locate an exact point, but really for risk
9 management and for higher-level data analytics that can be
10 embedded within to distribution integrity management plans.

11 Such as what's being done by Center Point in
12 Texas, is they use Picarro-based platforms to acquire more
13 data, run it through spatial analytics platforms. And to
14 look at where leak-prone pipes overlay with sensitive
15 receptors, overlay with age of pipes, and the actual
16 leakiness of those pipes to prioritize investment where
17 they can get the best bang for their buck. And to actually
18 start using methods that PG&E has also been using in terms
19 of grouping repairs by geographic and not just by
20 individual leak.

21 And we see of course also we can move from new
22 data at the utility level, but also at major point sources.
23 And as we've been able to have more and more data come in
24 showing now the randomness of high leak events in oil and
25 gas production sites, we see this now supporting the

1 regulatory tool of frequent monitoring, a requirement for
2 frequent monitoring.

3 And I think that even this year alone over the
4 course of the next two months we're going to see this new
5 type of data starting to feed into a regulatory process
6 right here in California. And in fact what we see is a
7 draft rulemaking that was released just last week, where
8 the Air Resources Board, while they include a quarterly
9 monitoring requirement for oil and gas production sites,
10 within that requirement they also allow what's known as a
11 step-down provision. And that provision allows for
12 operators if they don't find a leak for a certain of number
13 of quarters to move to an annual inspection requirement.

14 And now as we see, this new data and the new peer
15 review literature, say the only way you can really manage
16 these fat-tail leaks, these super-emitters, is by regular
17 quarterly inspections. We think this new data is actually
18 going to move the regulatory proposal to require permanent
19 quarterly inspections. And that's what I think the
20 environmental community feels that it needs, that's what
21 the science supports and that's where we think the agency
22 is likely to go.

23 And of course this is not just in the
24 requirements, but also in evaluating the costs of all these
25 requirements. And as more data on how much it costs to fix

1 various pieces of equipment or to change out emerges --
2 this is a macro we did with ICF Consulting a couple of
3 years back -- we can see that most methane reductions can
4 be achieved at a penny per 1,000 center cubic feet are
5 really -- essentially pay for themselves quite quickly.

6 And more data is coming out in stationary
7 monitoring. This is some work that we've been doing to
8 evaluate the idea for stationary methane detection and to
9 look at automatic leak detection at well production sites.
10 But really we sort of look at where the institutional,
11 where the continuous monitoring, where the ground level
12 monitoring, where this all takes us.

13 And we see that in a report we did called the
14 Rising Risk Report earlier this year we could see that
15 institutionally large oil and gas companies don't do very
16 well when it comes to reporting methane emissions, when it
17 comes to reporting methane reduction goals, and when it
18 comes to talking about methane reduction as a part of their
19 corporate policy.

20 And looking at the top 25 producers, and the top
21 15 midstream companies, we see that pretty much nobody
22 reports quantitative reduction targets in the oil and gas
23 space. These oil and gas majors they don't report on this
24 in transparent investor-facing documents. And in fact,
25 less than one-third actually talk about and report their

1 emissions. And so if companies are out there not talking
2 about emissions reductions or emissions in a transparent
3 way it becomes very hard to actually work through the
4 process of continuous improvement, of corporate management
5 that actually yields reductions.

6 And this the last slide of the presentation. And
7 here we talk about why we think all this important, why we
8 think this new data, this new data on reporting both
9 emissions, emissions reduction goals in a transparent way,
10 is so critical. And it's because when we have emissions
11 data we can engage investors and we can track progress.

12 And as we track progress and as we have engaged
13 investors there's a feedback loop, the feedback loop of
14 corporations and companies trying to do better because they
15 care what their investors think. They care about their
16 public perception of environmental performance. And they
17 also see that methane, of course, is not just about looking
18 green, but about actually saving the green. It's about
19 reducing loss of capital. It's about reducing the loss of
20 products into the environment.

21 And when we see statements such as \$20 trillion
22 worth of assets being represented saying, "We're
23 particularly concerned about methane. High-methane leakage
24 rates undermine the climate change benefit of using natural
25 gas as an energy source," we see the questioning of major

1 investments in new natural gas infrastructure, new
2 pipelines, new investments in gas plants starting to have
3 more scrutiny over the infrastructure they are managing.

4 And as we see higher and higher leak rates we
5 think that these types of statements over investor concern
6 and over the need for continuous positive improvement just
7 start to move the corporate bottom line, just start moving
8 this process. And this is only available, because of this
9 increased data that's permeating through the value chain.

10 So thank you very much.

11 MR. KURTOVICH: Thanks, Tim.

12 Our next speaker is from the Department of
13 Transportation PHMSA, and he will be providing his agency's
14 perspective.

15 Robert Smith graduated from Penn State in 1997
16 with a B.S. in petroleum and natural gas engineering. He
17 coordinated and managed the offshore pipeline in the Human
18 Factors Research Program at the Bureau of Safety and
19 Environmental Enforcement from '97 to 2003. And since 2003
20 he is currently an R&D Program Manager and leads several
21 strategic initiatives for the Pipeline and Hazardous
22 Materials Safety Administration.

23 MR. SMITH: Thanks for that. And thank you to
24 the symposium organizers for the opportunity to speak.
25 It's a pleasure to be here. I think I learned a lot

1 yesterday, a very good discussion and presentations. And
2 thanks to Martin for accommodating me. I have to leave
3 right after this session unfortunately, so most of my
4 presentation material seems to be better lent for the
5 afternoon session, but I'll let you be the judge of that.

6 There was a little bit of a high-level discussion
7 yesterday about what PHMSA's focus is and our mission, but
8 I wanted to be able to give you a little bit more detail
9 this morning.

10 We develop and enforce regulations for the safe,
11 reliable operation of well over 2.6 million miles of
12 pipelines, which I'll get more into in a little bit, with
13 over 2,600 pipeline operators both for hazardous liquid,
14 natural gas transmission, and distribution.

15 We also have a hazmat function. That's dealing
16 with the shipment of hazmat by all modes of transportation.

17 It's important to know that we've been directed
18 by Congress in a certain manner and that focus is primarily
19 on safety. We do have an environmental authority when it
20 comes to hazardous liquid pipelines. But for natural gas
21 it sits limited compared to our liquid authority. We don't
22 have an economics mission and we currently don't permit or
23 site new facilities or pipelines.

24 You may have heard that Congress is considering a
25 full statutory authority in underground storage. That's

1 something that we'll have to see with the reauthorization
2 that's occurring for our program right now. So here we'll
3 definitely have some new authorities.

4 The infrastructure, 2.6 plus million miles, it's
5 growing every week, month with new construction. As you
6 see me circle there, our box for the gas transmission
7 distribution, it's obviously largely gas distribution
8 pipeline infrastructure in the country.

9 This is just the hazardous liquid transmission
10 and gas transmission pipelines across the country that we
11 regulate. It does not show the distribution pipelines. If
12 we had the distribution pipelines on this map it would be
13 blacked out in many urban areas, if not already as you see.

14 We begin to take a look at our rulemakings and
15 follow the guidance from Executive Order 12866, which is to
16 understand what are the net savings either -- our
17 rulemakings. Does it create more leakage? Does it save
18 methane from being released?

19 We have to now conduct an analysis to understand
20 what we're doing in our rulemakings of course for safety,
21 but to understand if there's going to be a savings that we
22 can apply to the cost benefit that we're saving methane
23 from being released into the environment. So it's
24 something of a new area for us. We've applied it to the
25 current rulemaking on gas that I'll talk about in a little

1 bit.

2 This is kind of my catch-all slide. So what I
3 can say is that we're obviously very closely following the
4 developments. You know, the Whitehouse Action Plan,
5 Congresses' interests. Of course the action from the EPA,
6 who participated with the Quadrennial Energy Review. And
7 of course following what many of the pipeline operators and
8 trade organizations are doing across the country.

9 We've been coordinating with the EPA for a long
10 time now. We've been having meetings that share data. Our
11 data has a lot of thresholds of reporting, so there's not
12 necessarily a large aspect of the data sets that we capture
13 that's useful for the EPA in what they're trying to report.

14 We have participated in prior Gas STAR events for
15 the EPA, which have been very interesting. They cited some
16 of the technology that I'll talk about later, that we're
17 able to fund and get out to the market.

18 We have a long history of coordinating with DOE,
19 but we participated with ARPA-E and NETL. But when it
20 comes to things like research strategy reviewing each
21 other's research proposals and we're making sure everyone's
22 invited to either a key technology demonstration.
23 Particular if we're testing out new leak detection
24 technology that's something that we want to be able to
25 coordinate and invite, and I'll talk more about that later.

1 The Environmental Defense Fund, we've had several
2 meetings with the EDF. They've come in and briefed us
3 about many of their studies. We've also added, I think
4 it's Mr. Bernstein, to our Pipeline Advisory Committee.
5 Which that function, that's a congressionally mandated
6 committee that overlooks all of our rulemakings. So it's
7 an opportunity for the EDF to look at what we're doing and
8 comment on the rigor of these rulemakings when it comes to
9 methane reduction.

10 We've taken a hard look at our Part 192, our gas
11 regulations, to understand leak paths and see if there's
12 any actions that we can actually address in the future. I
13 do want to say that however our case in safety has been
14 largely been made with integrity management programs, which
15 I'll talk about in a little bit, with the focus as
16 hazardous leaks.

17 Non-hazardous leaks, once again we don't have an
18 economics mission; are more of an economic issue in nature.
19 So until our jurisdiction changes our focus will still be
20 on hazardous leaks first. But we are trying to do as much
21 as we can as an ancillary effect for smaller leaks as well.
22 And it may be a charge for other bodies like the National
23 Association of Regulatory Utility Commissioners or the FERC
24 or for Congress to give us new authorities in that area.

25 So our whole regulatory program is about keeping

1 the product in the pipe. That should be well understood.
2 Our mission is safety and we want to prevent accidents from
3 happening and that would prevent further releases to the
4 environment.

5 We started with, on the gas side in 2004, with
6 our gas transmission rule and implemented it in 2004, which
7 created new programs to prevent leaks. And to remove
8 anomalies before they reached an incident, which of course
9 would release methane. We follow that up with our
10 Distribution Integrity Management Program in 2011, which
11 has requirements to find and fix leaks as well.

12 We added excess flow valves to residential
13 service that will mitigate and minimize the amount of gas
14 that's released if there is a rupture in the line in a
15 residence past the meter.

16 For distribution in particular, excavation damage
17 is probably the leading cause of pipeline failure. So we
18 have a number of programs and policies to promote good best
19 practices. You know, call the nationwide "Before You Dig"
20 service, 811, to have that marked before you dig, and a
21 number of other programs.

22 Research and Development, we've been funding
23 research collaboratively with any interested party since
24 2002. We've brought overall about 26 technologies to the
25 markets since 2002, so it's a very good success rate. We

1 have a program of course in leak detection, but in also a
2 lot of strategic areas of damage prevention, anomaly
3 detection, and we've had successes in robotic inspections
4 on piggable pipelines as well.

5 So once again I mentioned we took a look at our
6 gas regulations so to understand where the leak paths are.
7 So we've got into a number of things here and realized that
8 in some cases some of the pressure relief devices and other
9 aspects in the parameters in the pipeline system can be
10 very difficult to take out. Perhaps we can have technology
11 that will maybe capture the gas or to flare in the gas or
12 something like that, so there is opportunities in the
13 future for that.

14 The rulemaking, right now we have one rulemaking
15 that's related to natural gas there. The main objective of
16 this rulemaking is to address several mandates that have
17 been given to us by Congress from a prior reauthorization.

18 And unfortunately that particular rule only
19 begins to have a process to talk about things like leak
20 detection, which the rule says will be handled in a
21 separate rule. Valve spacing and rupture detection once
22 again handled in a separate rule. And underground gas
23 storage is going to be a separate rule, as well. But the
24 rule also asks for comments about what's going to be
25 important in these areas from the public. Any stakeholder

1 has an opportunity to comment. We've reviewed those
2 comments and we'll be factoring that into the aspects that
3 we do with the separate rules for leak detection, valve
4 spacing and underground storage in the future.

5 It was mentioned yesterday we issued an Advisory
6 Notice after Aliso Canyon. We've worked significantly with
7 the State of California from our technical services. We've
8 learned a lot of things about this area, which is not an
9 area that we had significant jurisdiction in however it
10 brought to bear these reminders that we sent out in this
11 Advisory Bulletin to the industry.

12 There will be more to come on this as we
13 participate with DOE partnership on gas storage. We're
14 going to participating also in their events next month in
15 the Denver area that will identify gaps, perhaps, in
16 technology needs and policy.

17 We're holding an event the next day at the same
18 hotel that will get specifically into the safety focus of
19 what type of requirements are we going to need, what
20 standards are out there currently that we may incorporate
21 by reference, what needs to be improved in those standards.
22 And additionally, what technology needs.

23 Our R&D Program is there to serve our agency's
24 mission. We're really in the near-term outlook on
25 research. We're focused on safety and environmental

1 protection and reliability of the infrastructure.

2 I'm just going to kind of focus on our technology
3 objectives. We do have three objectives in our program,
4 but the fostering and development of new technology has
5 been a success area overall for us.

6 For our investment in methane leak detection
7 we've had eight awards since 2002. We've had many other
8 awards, but they were focused on liquid side. Eight awards
9 since 2002, you can see our investment breakout there. Of
10 that we've had three commercialized technologies I'll talk
11 about next. And these have been in successes to detect
12 methane.

13 Sorry for the small print. The first three were
14 the ones that were earlier commercialized, one of them
15 almost ten years ago. These were helicopter and fixed-wing
16 based platforms for LIDAR to detect methane. We also had
17 an in-service solution that can roll through the pipeline
18 and find where, by sonic listening, where those gas leaks
19 are in a system. So it's anything that will fit the type
20 of technology, so it can be used in transmission and
21 distribution along with just flow in the line.

22 The last three projects go beyond just detecting
23 methane. And they focus on the quantification, which is
24 where we need to be with technology research. In
25 particular, Project Number 6 listed there, I was told

1 indirectly from the EDF that that is the most important
2 project that is needed right now. And what that project
3 is, is we're working with technology and operators to come
4 up with not only the flow-rate measurement solutions, but a
5 framework on how to develop an action plan to remediate
6 those. When you see 5,000 leaks in an urban area how do
7 you get your arms around that as an operator? So it's
8 really kind of getting into that. It's working with ConEd
9 in New York City, a number of operators in other cities as
10 well.

11 And the other two projects as well looking at
12 different types of technologies to better quantify the leak
13 by stand-off distances.

14 So research coordination, we're doing things like
15 inviting people in to review our research proposals that
16 are submitted. We're inviting people to debrief meetings,
17 meetings, project meetings, tech demonstrations. We're
18 working with all the states, the EPA and DOE as you see
19 listed there. Just recently the ITRC, that's a very
20 excellent organization, they just kind of share best
21 practices and understand what's going on with technology.

22 We periodically hold an R&D forum. We're trying
23 to secure a hotel right now. We're trying for the fall of
24 this year. This will be announced in the Federal Register,
25 it's a public event. Anyone can attend. Usually we have

1 200 to 250 people, several breakout working groups that are
2 designed to come up with topics for us to solicit for, so
3 we get a collaborative approach to identify the priorities.
4 We don't duplicate that. And we invite in other
5 organizations and DOE and EPA.

6 We had the EDF actually participate in one of our
7 prior ones. They actually came up with the topic that I
8 mentioned before that we funded. This particular one, we
9 have one on leak detection. I think the focus is going to
10 be a lot on liquid. However, when I think it comes to line
11 break and valve detection we are going to still have a
12 focus on gas. Underground storage, there's going to be a
13 complete working group on that to come up with a number of
14 topics as well as leak detection topics within that group.
15 It's a little bit overlap there.

16 Our broad research suggestions, I think we kind
17 of heard that we've reached the end of the road on
18 detection research. Unless we're really trying to get that
19 as cheap as possible, once again that's not our mission.
20 We're trying to look at it as an effective technology,
21 costs are a consideration. We should be leveraging the
22 prior successes and collaborating together. ARPA-E of
23 course, those projects are ongoing. And it should say DOE
24 NETL's upcoming investments in leak detection, as well.

25 I think there's basically a broad roadmap that

1 exists already between the EDF and ICF reports when it
2 comes to areas that we could lower the costs and kind of
3 get some low-hanging fruit and improvements and capture
4 that gas now. And many of you are familiar with this. I'm
5 not going to get into the details, but I think the goal
6 should be to try to reduce costs as much as possible down
7 to create even more of an incentive for pipeline operators
8 to stop these leaks.

9 Okay, before I conclude I want to mention cast
10 iron. We have a lot going on in cast iron. Our prior
11 Secretary of Transportation issued a call for action to
12 accelerate the replacement or rehabilitation of cast iron
13 systems. As you can see by the information below, it's
14 going to be quite a while yet before we can replace these
15 systems nationwide, mainly in the northeast cities. We
16 want to give operators more incentive to replace these
17 lines, so we're developing technology to look for graphitic
18 corrosion. So we can understand there's more reasons to
19 replace that particular section or that entire system.

20 We are looking at liners too. We want to be able
21 to understand if we can line these systems to quickly cease
22 the leaks and then to come back at another point and
23 replace them. Or have liners that have such an integrity
24 they can be a carrier pipe for themselves. So there's
25 still a lot of research going on to try to create further

1 incentives to replace that infrastructure.

2 So final thoughts, uniform picture, I think we
3 had a pretty good scientific discussion yesterday. I think
4 we would argue that we're still kind of recovering from
5 trying to merge a top-down and bottom-up approach, so I
6 think we need a few more years of focusing on the bottom-
7 up. But top-down definitely from a screening tool-type of
8 approach.

9 Technology solutions I mentioned, I think we're
10 pretty good on detection. But quantifying leaks is
11 something of an area of stale research, and hopefully some
12 of those projects I mentioned pan out.

13 Cost recovery, this is something that is a rate-
14 constraint environment. There's really only so much money
15 in the pie for operators to put towards their operations.
16 And so if we see not a rate-recovery case made for methane,
17 you know, that will have an impact on safety so that's
18 definitely a concern that we have moving forward.

19 And I was just a little bit late, so I appreciate
20 that. Thank you.

21 MR. KURTOVICH: All right, thanks Robert.

22 Next up we have Dr. Cynthia Powell. She is
23 currently the acting Deputy Director for Science and
24 Technology Strategic Plans and Programs at the National
25 Energy Technology Laboratory where she leads a

1 comprehensive research effort to discover, develop and
2 deploy technology solutions that will make sustainable,
3 affordable fossil energy production and utilization a
4 reality.

5 Prior to this current appointment Dr. Powell led
6 NETL's onsite research organization.

7 Material sciences by education, Dr. Powell has
8 several decades of research experience in the micro-
9 structural development of engineered materials at service
10 conditions and the effects of these changes on materials
11 performance. She received her Ph.D. in Material Sciences
12 from Case Western Reserve University, preceded by a M.S.
13 and B.S. in ceramic engineering from Clemson University.

14 MS. POWELL: Good morning, everyone. So I'm
15 going to spend just 10 or 15 minutes talking to you about a
16 new program within the Department of Energy's Office of
17 Fossil Energy, which is a natural gas midstream research
18 and development program.

19 So first of all I just want to pause for a
20 minute, because Natural Energy Technology Laboratory, many
21 of you know of NETL as a program and project implementer.
22 But I also want to remind you all it's also one of the DOE
23 national laboratories with a significant capability in
24 research and development focused particularly on the fossil
25 energy mission and particularly on the sustainable

1 production utilization of those fossil energy resources.
2 So more than a century of R&D expertise aimed with
3 competencies that are of particular interest to this
4 program in things like geological and environmental
5 systems, big data analytics, life cycle analysis, material
6 science and engineering where obviously I have a particular
7 interest. So that is in NETL, but let's go on.

8 So we've heard over the last day plus a bit about
9 the importance of understanding methane emissions and the
10 importance of not just collecting data, but then using that
11 data to take action to mitigate or to make changes in
12 operations, best practices and in example.

13 The driver for the methane emissions program that
14 I'll speak to in more detail in a few more minutes really
15 came from President Obama's Climate Action Plan where that
16 plan recognized methane emissions and the importance of
17 methane emissions in contributing to overall greenhouse
18 gases and global warming, really pointed towards a
19 multiagency approach to addressing this problem.

20 We've talked a lot about the integration of
21 efforts between the Department of Energy, which has a
22 research focus, and between the other agencies that have
23 more regulatory focus: DOT, PHMSA as part of DOT, EPA. And
24 so everything that we're doing is very much organized and
25 complementary in terms of effort and a lot of conversation

1 going on per the President's request and his Action Plan.
2 And really the goal here is by 2025 to reduce methane
3 emissions by 40 to 45 percent relative to 2012 levels. So
4 that's the end goal.

5 And the program that NETL is implementing on
6 behalf of the Office of Fossil Energy is addressing two of
7 the three pillars in that interagency methane strategy.
8 One is to assess current emissions data and address data
9 gaps. That is the methane quantification part of the
10 program.

11 And then the other aspect is identifying
12 technologies and best practices for reducing emissions.
13 That is the mitigation piece of it.

14 The third pillar really speaks to policy, which
15 is outside of DOE purview.

16 So we have been doing research in this space.
17 This is not the first time we've recognized this is a
18 problem. And so I just want to call folks' attention to
19 the natural gas infrastructure R&D program that occurred
20 between 1999 and 2005, which really had some good
21 successes. It was a six-year program, all the way from
22 technology discovery development to field implementation
23 and actual commercialization of a range of technologies,
24 ranging from aerial and point-source leak detection to sub-
25 mitigation strategies with regards to pipeline repair and

1 inspections. And also some improvements in things like
2 compressor design.

3 So this program I think really laid the
4 groundwork, planted some seeds. Many of the successful
5 performers in this program are now participating in the
6 ARPA-E, sort of revolutionary R&D efforts that are ongoing
7 and are likely to continue to be partners in the emerging
8 methane quantification and mitigation program that NETL is
9 leading. So we're not new to this, we've been doing this
10 for a while.

11 And even more recently before the onset of this
12 program in the unconventional natural gas and oil program,
13 NETL has been looking at trying to gather more data from
14 field assessments recognizing that there really is a
15 limited number of high-quality field data sets. And
16 particularly focus in that case on shale gas operations.

17 So six projects ongoing, the list of performers
18 are there, and really the goal here is to get data, to get
19 high-quality data. And then to implement that data in
20 modeling and simulations that can improve understanding and
21 learning.

22 All right, so this is a rather busy slide. These
23 are the six projects. And it kind of gives you an
24 indication of what their focus is on. These are three-year
25 projects. They are going to be ending at the end of fiscal

1 year 2017. A range of performers or a range of different
2 basins, a strong focus on the Marcellus, but a couple of
3 other basins as well. And you'll notice that these
4 projects are focused on a variety of sources in addition to
5 just gas production. Many of them are focused certainly on
6 methane, but other emissions as well and use a variety of
7 platforms.

8 I'm going to speak just really briefly to two of
9 those, those two that are highlighted. But you'll have
10 these slides and have the opportunity to explore this in
11 more detail at your leisure, so the first one that I just
12 want to highlight here, is the work that's happening at the
13 National Energy Technology Laboratory.

14 We're focused on the Marcellus and really focused
15 on an understanding of the full life emissions of shale gas
16 operations from predevelopment of a site, through
17 development production, and then coast site emissions to
18 really understand what is happening across that full life
19 cycle.

20 We have a variety of capabilities that we bring
21 to the table in that from ambient air monitoring. You'll
22 see in the upper left a trailer that we can pull to a site
23 and measure a variety of things: methane, VOCs and
24 etcetera. We're also looking at aerial detection
25 methodologies, a strong aspect of this program too is

1 identifying where abandoned or legacy wells -- mostly
2 abandoned wells that we didn't know existed, where they're
3 actually at -- ground-proofing their location and then also
4 understanding the emissions from those previously unknown
5 sources.

6 A second project among those six that I just want
7 to highlight is one I think we heard about yesterday being
8 led by the Colorado School of Mines in collaboration with
9 NOAA, which is looking at methane emission estimates from
10 natural gas sources at the basin and the facility level,
11 trying to reconcile the discrepancies between the top-down
12 approach and the bottoms-up approach.

13 And again we heard a little bit about this
14 project yesterday. In the fall of last year over 230
15 natural gas facilities were interrogated and preliminary
16 results showed, not surprisingly, they did observe the fat
17 tail. And really recognizing -- we're beginning to
18 recognize importance of both measurements plus an
19 understanding of what is being measured at the time the
20 measurements occur to really get into quality data.

21 So now here in fiscal year 2016 we have funding
22 to initiate and expand our methane quantification programs.
23 I've already talked to you about how the unconventional oil
24 and gas program is already taking a look at shale gas
25 production sites. And now we are expanding the methane

1 emissions quantification effort more broadly to explore the
2 midstream. So what that means in terms of research
3 elements is trying to gather more data and gather high-
4 quality data from a variety of different sources. From
5 gathering systems where data is scarce, so in some cases
6 non-existent to also getting better information about those
7 non-inventoried sources like the abandoned or legacy wells.

8 We're also going to begin looking at distribution
9 centers as well as large-scale underground storage sites in
10 terms of gathering information. And then once we have that
11 information we want to take use of that, so we're beginning
12 to input that data into life cycle analysis. And this
13 data, this whole program definition has really been
14 strongly in collaboration with EPA. And so our early
15 emphases are in areas where they say they particularly need
16 information in order to improve their greenhouse gas
17 inventory.

18 And next I'll talk to you about how we're going
19 to actually implement the partnerships that we speak about
20 here in terms of the funding opportunity announcement.

21 So the second part of that program is really
22 understanding emissions mitigation. And so this is all
23 about you know you have a leak, what are you going to do
24 about it, in essence? And so a couple of emphasis for this
25 new aspect of the methane's mitigation program really

1 focuses on understanding or developing sensors, so that you
2 know what is happening in the field in real time. Point
3 sensors that can do things like monitor corrosion rates in
4 pipelines, so you understand pipeline health and have
5 predictions for when you might have failure or when you
6 might need to go and do service, also optical sensors that
7 can interrogate pipeline health.

8 Other areas of emphasis will be in advanced
9 liners and coatings. Of particular interest could be a
10 combination of coatings that would be protective of the
11 environment, so protect that pipeline infrastructure as
12 well as the sensing and being able to provide data and
13 information about what's happening in the system to further
14 enhance and understand performance. As well as to be able
15 to offer suggestions for when pipelines would need to be
16 addressed and serviced.

17 So another aspect is the pipeline inspection and
18 repair. And the emphasis here really is on let's be able
19 to do that without having to vent methane. So we'd like to
20 be able to make inspections and repairs with the methane in
21 place in the pipes.

22 So those of you who follow this sort of thing
23 will hopefully already be aware. There is a funding
24 opportunity announcement out there to support these areas
25 of research in this program that I just talked about. That

1 FOA opened on April 13th and it closes this Monday, June
2 13th. If you need additional information about that FOA
3 you can go to the NETL website, look under "Business
4 Opportunities" and you will find a link to that site. And
5 you will find all the information you need to have in order
6 to be able to respond to this funding opportunity. The one
7 thing though again I want to emphasize, it closes on Monday
8 all right, so time is short.

9 The only other thing that I wanted to just draw
10 your attention to that we're doing right now is, really
11 this Natural Gas Storage Task Force again was talked about
12 yesterday that was developed in response to the Aliso
13 Canyon event. And NETL is working with several other
14 national labs with the wellbore integrity team.

15 And the thing that I really want to point out is
16 -- Robert already mentioned this -- there is a link over on
17 the mid-right of this slide for that workshop that's
18 happening in Denver Colorado, July 12th and 13th. And that
19 conversation will be all about wellbore integrity issues
20 associated with long-term underground storage.

21 And really, DOE has a wealth of expertise and
22 understanding of wellbore integrity for a variety of other
23 applications to include oil and gas development and
24 production, as well as Co2 storage. And our national labs
25 have already been working together in something called a

1 National Risk Assessment Partnership, which really takes a
2 look at what are the risks towards long-term storage of
3 things like Co2, things like natural gas. And it does
4 touch on wellbore integrity as part of that. So the labs
5 are already well positioned, having thought about this for
6 other problem sets to bring their expertise to bear in this
7 conversation of underground gas storage as well.

8 So their work, the task force work is expected to
9 be complete by the end of September. There will be some
10 best-practices reports as a result of that. And like I
11 said a good opportunity to leverage DOE expertise developed
12 in other areas to this very relevant concern about wellbore
13 integrity with natural gas storage.

14 And that puts me with 56 seconds left, so thank
15 you very much for your attention. It's been a pleasure.

16 MR. KURTOVICH: All right, next up is Keith
17 Driver. Keith is with Cap-Op. He has developed a broad
18 skill set in experience North American regulatory and
19 voluntary carbon markets, has been a key contributor and
20 developer of Alberta's provincial offset quantification and
21 trading system as well as other systems across North
22 America. He co-founded Cap-Op Energy as a consulting and
23 software company, with the objective of making
24 sustainability, profitable for the oil and gas and
25 bioenergy.

1 A serial entrepreneur, Mr. Driver has more than
2 13 years of experience in the environment industry. His
3 current areas of interest include fuel and energy
4 efficiency, bioenergy, carbon finance and clean tech
5 development.

6 MR. DRIVER: Thank you, everybody. My experience
7 in this space is -- I've been struggling with, it's a lot
8 different than everybody else, the speakers we've had so
9 far -- I started about five years ago getting very
10 interested in this space at a very similar meeting in
11 Banff, Alberta. We were talking about the difference
12 between engineered leaks and fugitives and what we could do
13 about those.

14 And so Cap-Op was eventually born from that,
15 because what we realized or what I realized at the time is
16 that one of the challenges is really about data. So we can
17 do projects, but we don't know how successful they've been
18 especially on the engineered leak side until we track the
19 data afterwards. And so thus we ended up.

20 And so that's how I got into this space and it's
21 how I got into this conversation, it was a conversation
22 with Tim at EDF. And the objective of our conversation or
23 what we were thinking about was how to really make
24 sustainability profitable in California. Because the
25 objective is reduce the carbon footprint intensity of

1 natural gas delivered into California, not comes from
2 places where I work, outside of California, nominally 90
3 plus percent.

4 And the things we needed was we needed tools, we
5 needed things to make that possible so that it's not so
6 much, "Oh well, it's a big system and it's integrated. And
7 the sites are all over the place. And how are you going to
8 go about doing this?"

9 And so these are the things we have. I going to
10 come back to this slide at the end and I'm going to add two
11 bullets where there's gaps. It's foreshadowing; work with
12 me on this.

13 So Cap-Op Energy, what do we do? We build
14 software tools and provide expertise consulting services
15 and strategic thinking to help companies actually get to
16 reductions. So not necessarily as many other speakers have
17 been focused on finding them, in our world a lot of them
18 are designed into the system. So if you tell me what your
19 system is I can tell you where your leaks happen, because
20 they are designed to leak and there's a rate at which they
21 leak. And so we focus primarily on those.

22 And then those that might be more described as
23 "fugitive," which is sort of the super-emitters of those
24 that happen on occasion or they require other sampling
25 methodologies.

1 It's the opportunity, the mandate that well we
2 live in, in Canada as well in the U.S., is a 45 percent
3 reduction in methane emissions in oil and gas sites. I for
4 one believe this to be inherently possible. And I think
5 we've seen some slides, maybe from Tim earlier, that talked
6 about how there's technologies out there to get there. The
7 question is 45 percent of what? If there's anything we
8 learned yesterday is that the emissions are possibly
9 underreported by 100 percent, so 45 percent of what number?
10 Because one is 145 percent and one is 45 percent.

11 And those numbers are currently more difficult to
12 comprehend and to get our act around.

13 We know in Canada from the work we've done that
14 the cost of abating those emissions from engineered sources
15 ranges from \$2 to \$160 at a time depending on how you plan
16 for, identify, track, report those emission reductions.
17 That's an 80 times difference in price, depending on which
18 ones you go after, and which ones you go after first. If
19 you're industry, \$2 a ton isn't so bad. If you're a \$160 a
20 ton it's not a (indiscernible).

21 And to give you some sense of how big the pie is
22 these numbers up here for Alberta, these are five
23 technologies for which there are technologies off the shelf
24 to replace previously engineered leaks. So for those that
25 understand engineer leaks, some pneumatic devices release

1 methane and it's part of how the system was operated. And
2 it was always done, because methane is cheap or was at the
3 time. It didn't have an impact.

4 So if we look at how many high-bleed devices
5 there are in Alberta there is 370,000 of them. We think we
6 could probably get to 115,000. And reasonably that's 46
7 megatons of GHGs that could be reduced just by going after
8 something we know is there. So before we spend all our
9 time going after the things we don't know are there yet
10 there's stuff that we can go after right away. And there's
11 five other technologies that are on there, adding up to
12 about 300 million tons just in Alberta. Now we are not all
13 of California's source, but we are indicative of
14 California's source measurement of natural gas.

15 So the opportunity, again the more \$2 projects we
16 can find, the less \$160 projects we can find, the more
17 financeable, the more momentum we can get behind why energy
18 efficiency is important.

19 We look at this as a continuum. I'd love to tell
20 you we started out looking at this and knew left to right
21 was the way to go. We started off at the far right-hand
22 side of this thing, which was how to help people verify and
23 report projects they had already done. That was the
24 problem. They had no data, they didn't know if the project
25 they'd done last year was worth doing again. So everything

1 was a one-off. So we started doing that. We created this
2 DEEPP platform and I'll get to that in a second,
3 "Distributed Energy Efficiency Project Platform."

4 We then started working backwards, which is
5 "Well, they don't know what equipment they have out in the
6 field. Don't know where my compressors are, don't know
7 where my pneumatics are. We don't keep those kind of
8 inventories." So we have to go back, we have to move back.
9 And we created the MAP tool, which is the "methane
10 abatement platform," which allows them to go and do
11 inventories of these emitting pieces of equipment further
12 back.

13 It fits on your cell phone. I feel silly being
14 up here and have people up here from NASA talking about
15 satellites. And all I need to find emission reductions is
16 my cell phone. It's a bit of a different perspective, both
17 rooms (indiscernible) to be done.

18 On top of that if you know what those projects
19 are going to do, because you've done them before and you
20 know where those projects are you now know how to create an
21 investment tool, a finance tool that allows projects to
22 happen, allows multi stakeholders to get engaged. And
23 that's where this innovative funding comes in and I'll talk
24 about that in a minute. So the MAP tool, real simple, a
25 bunch of drop-down menus on an iPhone app allows you to go

1 out to a site, look at all the different types of
2 equipment, and create inventories of methane-emitting
3 equipment.

4 Once I know what equipment's onsite I can tell
5 you what those emissions are. Not what they are by
6 manufacturers' spec, because we know those numbers aren't
7 right. It's why I know my car doesn't get the mileage that
8 Honda tells me it's going to get. It's the emissions that
9 we have seen in the field. We have gone and measured 2,000
10 pneumatic devices in the field to create statistical
11 averages of what they actually are in the field. So we can
12 look at that data set and if I have your inventory I can
13 match it up and say, "Yeah, if you go up to this field over
14 here" -- here's the drop-down menus, it doesn't make for a
15 great slide but I'll keep talking -- is if I know where all
16 those are I can tell you where to go. "In your truck take
17 eight of these things. Go over into this field. These
18 four well pads are the ones to hit."

19 The difference between a \$2 project and a \$160
20 project is how long it takes someone to drive around in the
21 truck. How many times they have to go out to site. How
22 many times they have to collect data. So if they can know
23 where those things are and they can be efficient in how
24 they operate those projects, make that work.

25 So we then layer that across where there's

1 utilities, so can they tie that gas into pipelines? Can
2 they work with partners that are operating on nearby sites?
3 Can we look at how to manage a campaign to make this happen
4 efficiently?

5 Once those projects are in place we have our
6 distributed energy efficiency project platform. Let's take
7 the data, the operating data in the field, the activity
8 data that's there and pull that into the system GIS, so we
9 can look at where we're seeing our emission reductions
10 happen and how successful are they. We look up on the
11 slide there on the right is the map of all the projects
12 that are done in air-fuel ratio controllers on compressors,
13 in reciprocating engines. So on the engines changing the
14 air fuel ratio going in by putting a little computer chip
15 on the front end that tells us how to manage that, we can
16 then pull in vented gas from the site, put that into the
17 compressor, run the engine more efficiently. You save
18 fuel, save GHGs.

19 We can track which engine, so if you can tell
20 which engine you have I can tell you which ones tend to
21 respond better to this technology, which one has a higher
22 rate of return. I can show you yours, I can show your mom
23 yours, I can show you across the full data set of the ones
24 that are out there. Particularly proud of this, because we
25 touched two-and-half million emission reductions so far,

1 just looking at stuff for which there is existing
2 technology available.

3 How do we do it? Well, the flow chart on the
4 left is meant to be confusing. It's to convince you to use
5 our service, which says, "This is how you go out and get an
6 offsite credit." You have to go out; you have to track all
7 the data. These are onesy-twosies, these are little 50 ton
8 projects, 100 ton projects. You've got to send someone to
9 the site, it doesn't work.

10 We created an aggregation platform and system
11 that says, "Great. We take all the data. We put it all in
12 one system. And it's completely auditable. Aren't we
13 wonderful?" The reason it works is we may charge \$4 and
14 something to get that out, which in Alberta the market
15 price is \$15, so we're a net ahead. But to do it on your
16 own and to do it at one-offs can be at least twice that
17 expensive.

18 This chart has two functions and I'm going to
19 talk about them quickly, because I know my time is running
20 out. I've only got six minutes left. We learned two
21 things about this, about oil and gas. Is one, you can
22 separate environmental attributes from the gas savings. So
23 within the company you've got the folks in the field.
24 Their jobs are safety, production, production, production,
25 production, reliability. Those are their priorities.

1 "Environmental, cheap greenhouse gas, I don't care, I don't
2 believe in it," whatever the case may be.

3 You have corporate who's got environmental
4 compliance obligations. "Yes, we need performance and
5 reliability. Yes we need health and safety, but we also
6 need to comply or we need to show a movement on methane.
7 We need to hit targets."

8 So you have these two cycles that are slightly
9 different. On the right they just want reliability and
10 operations. The other side of this is you can actually
11 separate the emission reductions from the environmental
12 benefit. Think of this like green electricity. We can
13 sell RECs, we can sell power. We can sell them bundled and
14 we sell them unbundled. We can do as we wish.

15 So we've looked at this and said, "Great. If I
16 can create this program I can split off on the one hand the
17 blue side of this where the field guys get the equipment
18 they want. They can put it in, they get the gas savings
19 they need. And that pencil's for them."

20 We're giving them that equipment or for giving
21 them a rebate on that equipment. I'll take all the
22 environmental benefits of that. I'll put it through my
23 system, I'll quantify that. And I'll sell what is now a
24 separate asset class. I'm investing with oil and gas, but
25 not in oil and gas. So if you look at the \$20 trillion

1 that's looking to move away or looking to be thoughtful
2 around what it's doing with methane and there's a subset of
3 that that's looking to divest, it can't divest from energy.
4 Functionally it changes the asset mix in the portfolio.
5 But what they can do is invest in alongside -- invest in
6 the environmental side of those companies as opposed to in
7 the core assets.

8 So bundling all that back together we now have
9 tools that are available today and scalable around the
10 world that can help people build the inventories they need
11 to understand what assets they have. Help them identify
12 and plan projects, help them execute and track the savings.
13 Once we've tracked those we can flow them around between
14 all the stakeholders. Once we've cut that pie up we can
15 then feed that pie separately. And that sort of allows us
16 to create this separate pie as planned.

17 We're going back to the original question, which
18 is how do we reduce carbon intensity of natural gas to
19 California? Well frankly we need to get on the ground in
20 places like Texas, Alberta, B.C, Four Corners, Colorado.
21 We need to get on the ground. We need to do the basics of
22 getting inventories. We can fly over them all we want and
23 we should. Don't get me wrong, but there's also a list of
24 everything that we could do that's already available from
25 an engineer perspective. All of those solutions are there.

1 We have the tools and we have the ability to track them.
2 We have experience in other things like renewable energy.
3 We're in the low-carbon fuel standards that allow us to
4 move these values around and track them appropriately, with
5 or without functioning (indiscernible).

6 What we don't have necessarily in California at
7 this point is what we were talking about yesterday, a
8 breakout session was how do we create and support a
9 regulatory framework? Do we put a price on carbon like
10 Alberta where we have an offset system that reflects that?
11 In California you can't get an offset for a pneumatic
12 device installed despite the fact that that was written for
13 California. We took that and used it in Alberta and we get
14 credits and we get a functioning market and we get activity
15 happening.

16 The other thing we have is how do we mitigate the
17 risk of capital flows out of the state? If we can create
18 value for creating those emission reductions, we've seen
19 all the MAC curves that show that these projects can
20 actually be profitable, can show that and we can
21 demonstrate that and we can provide the tools to make those
22 happen at those costs. In theory the net value to
23 California is positive, because gas becomes cheaper,
24 because it's cheaper to produce, because there are savings
25 in the system that aren't being realized. So there is a

1 transaction cost or a cost that's being lost. Fugitives
2 are just lost that we talked about it in the earlier
3 presentations.

4 So last message -- we have tools, we have data
5 sets, and we have experience in how to take these projects
6 or the methane -- the 45 percent -- out of that system.
7 It's about linking the policy with the science to get us
8 there.

9 Okay. Thank you very much.

10 (Applause.)

11 MR. KURTOVICH: Thanks, Keith.

12 Next up is San Gunawardana with Enview, which is
13 a San Francisco startup. Now San, after finishing a PhD in
14 aerospace engineering at Stanford went to Afghanistan where
15 he combined data analytics and remote sensing to detect
16 threats and prevent incidents. San is applying those
17 insights to help the energy sector solve impactful
18 problems. He's also done computer vision at NASA, built
19 imaging satellites with the Air Force, and is an early
20 employee at ICON Aircraft.

21 MR. GUNAWARDANA: Okay. So I'm going to be
22 talking a little bit about big data and big challenges.
23 So the pipeline industry and the methane industry is
24 embarking on this very interesting big data challenge. And
25 it's actually interesting, because there's a very analogous

1 situation that the electric transmission industry went
2 through a few years ago. And the story is very similar
3 that there was a catalyzing event. There was a decision to
4 embark upon a large, remote sensing data collection, and
5 then many lessons that came out of that. And I think a
6 lot of those lessons could be useful and insightful to the
7 audience here.

8 To really quickly describe what we at Enview do,
9 our mission is to turn massive data sets into operational
10 intelligence that benefits safety and reliability. And
11 there's three key components behind what we do. We're very
12 much a big data analytics firm. The first component is the
13 fact that we fuse multiple sources of sensory data, things
14 like imagery, LIDAR scans, infrared visual imagery,
15 satellite imagery, etcetera. And automatically find
16 observations.

17 We also do a lot of big data analytics using
18 machine learning to move to a predictive stance to identify
19 threats. And the last key component behind all of this is
20 the data visualization. And I think as you'll see when you
21 talk about big data the visualization is very important,
22 because this is the data is large enough that it's hard for
23 people to really understand intuitively.

24 What sorts of things do we do at Enview? A
25 couple of really quick vignettes, a lot of work on

1 vegetation obscuration, a lot of work on third-party dig-
2 ins, depth of cover, measurements for pipelines, structure
3 counting, right-of-way encroachments, and then a lot of
4 predictive analysis for things like leak and rupture
5 prediction. And this is all being done automatically using
6 big data.

7 We also clearly do a lot of work with power
8 lines. And some of those discussions are going to form the
9 core of my talk here. So what was the catalyzing event for
10 the power line industry? Well, it was the 2003 Northeast
11 Blackout. A tree branch hit a power line and knocked out
12 power to a very large portion of the country for several
13 days. And as a consequence there were a lot of outcomes.
14 And the first was that there was regulation that came out
15 for maintaining vegetation clearances, thermal ratings of
16 power lines, etcetera.

17 And there was a previous manual solution that the
18 industry used to assess these things. And that manual
19 solution did not scale to the size of these new
20 regulations. So the industry turned to this very powerful
21 new technology, LIDAR. And just to clarify the LIDAR that
22 I'm talking about here is a little bit different perhaps
23 than some of the LIDAR sensors that may have been discussed
24 earlier. This is a similar technology, but really the
25 LDDAR here is being used to generate 3D models of the

1 world. It's essentially a glorified laser range finder
2 that builds 3D point clouds of the infrastructure. And a
3 lot of this was collected aerially via helicopters and air
4 mapped.

5 Now there's a problem with this. And the problem
6 is that LIDAR data is massive, it's gigabytes per mile and
7 it's petabytes per operator. And that energy that I'm
8 showing there is a mile of lighter data that we've
9 collected and classified. There's about 19 million points
10 inside that one mile and it's about 5 gigabytes. All
11 right, so extrapolate that to an operator with 10,000 miles
12 of pipeline or power line in this case and you suddenly
13 have a very large data problem.

14 And this position to go into LIDAR kind of pushed
15 this entire ecosystem into a big data challenge. And it
16 was the regulators, the electric transmission operators,
17 the LIDAR surveyors and also the LIDAR sensors themselves.
18 And I want to be very clear these four groups are all
19 incredibly skilled comps and groups within their own areas
20 of expertise, but nobody had ever gone and collected data
21 this big at such a rate.

22 And so as a consequence there were many
23 interesting painful lessons that were learned by this
24 industry that as I said should be applied to what's
25 happening now in the methane leak detection side.

1 So why is methane leak detection an analogous
2 problem? Well, it's going to have the same impact for
3 pipeline operators. It's a very big data challenge. The
4 area is enormous. Those numbers, that 1.5 million miles,
5 is just national gas. It does not include gathering lines,
6 which are I would say an even bigger problem. The
7 frequency is very different from what the electric
8 transmission industry did. They did a kind of a one-time
9 snapshot, which cost tens of millions of dollars per
10 operator. With the methane leak surveys this is more of a
11 continuous, ongoing process. So you're generating a
12 tremendous amount of data.

13 The complexities are arguably much higher,
14 particularly for the passive sensors where you're trying to
15 identify the source point origin of a leak. You have to
16 take a lot of physics and a lot of environmental factors
17 into account to derive back to where that leak started.
18 And the quantity to be frank is something that has yet to
19 be determined, but it's very large. I think there's been a
20 lot of fantastic work that has been done by the sensor
21 developers to identify how much data they're collecting for
22 that particular sensor. But when you deploy that scale and
23 you take into account all the other geospatial data that
24 has to be fused with that, it's very much an unknown at
25 this point.

1 And I think we can all agree that methane remote
2 sensing is kind of the future for this industry. It's
3 something that we'll all have to deal with. And the
4 pipeline operators can learn from some of these painful
5 lessons that the electric transmission industry has been
6 and is currently going through.

7 So I'll go through a couple of lessons learned
8 and the first one is on data rights. And what's the
9 problem here? Well, many operators are challenged to
10 actually process and analyze the raw data, because of the
11 quantity. And so they turn to third-party vendors who are
12 experts in this area. And it's a very natural reaction.

13 However, what we have seen is many of these
14 vendors used a proprietary data format. And there's some
15 sound business reasons, perhaps, why they would want to do
16 that. It kind of locks you into an ecosystem. But the
17 challenge is that now as an operator you can't get your
18 data out of that ecosystem. And this is painful, right?
19 So the lesson is don't get locked out of your own data.

20 And this sounds kind of obvious, but the first
21 time you're looking at a lot of this data you may not
22 understand the difference say between a derived result,
23 which is there is a leak here versus all the raw data that
24 went into forming that conclusion. And I think it's really
25 important to make sure that the deliverables include not

1 only that end result, but all of the raw data. And this is
2 incredibly important, particularly for big data, because
3 all these machine-learning algorithms and approaches are
4 very data-hungry. And they learn from different incidents
5 in different places.

6 So as an example we do some work here in
7 California. In California, it's very difficult to trim
8 vegetation just due to the sensitivity of the society here.
9 And so we developed techniques that enable our clients to
10 see through that vegetation. And now if you go over to New
11 Jersey it turns out they have a similar problem. And so we
12 can take our lessons learned from California and then
13 deploy those out in New Jersey.

14 And to flip that around, we some clients out in
15 Appalachia that have a lot of landslides occurring in their
16 pipeline network. And the machine-learning algorithms can
17 take that data, learn from that, and then apply those
18 lessons here in California. Now this is interesting,
19 because you can only do this if the data is interoperable.
20 So you really do have to make sure that you have access to
21 that data and that's it's stored in open-source format that
22 everybody can access.

23 A second problem or lesson is data retention. So
24 the vendors, in this case I would say the surveyors, who
25 were very qualified geospatial professionals were frankly

1 unprepared in some cases to deal with this very large
2 quantity of data. And so they did a few things to ease
3 that transition. And one is they stored the data in
4 traditional, let's call it small-data storage methods,
5 which end up being horrifically expensive. On the order of
6 we've seen as much as \$2,000 per terabyte per year. All
7 right, this adds up very quickly if you compare this to the
8 cost of a modern IT infrastructure that -- an AWS with
9 sensitive cloud infrastructure can deploy -- this is orders
10 of magnitude bigger than what it should be.

11 But one of the things we've seen vendors do is
12 that they threw out "non-essential data." And I'm showing
13 two examples of that here from a power line company. In
14 this case the vendor went out and they collected LIDAR data
15 at a very high resolution. And they decided that it was so
16 much data, and their client only really cared about the
17 power lines, right? They didn't really need to know much
18 about the ground, the buildings, the vegetation and so they
19 decimated all of the other points except for the points of
20 data coming directly from the power line. And they had a
21 huge savings in data storage and processing.

22 Now the consequences, several years later this
23 company now wants to do change detect (phonetic) from the
24 ground to understand how their clearances have changed.
25 They want to identify whether there's new structures and

1 they don't have that data and that data doesn't exist
2 anymore. And they paid a lot of money to go collect it.
3 And this is a huge loss of information and there's a huge
4 cost to this company, because they had to go recollect it
5 now.

6 And so the lesson here is, once again, like don't
7 throw out your own data and store all the raw data. And
8 there are things that you can do to do this much more
9 efficiently.

10 And just for comparison those two pictures,
11 they're kind of small, but that is literally the same spot
12 on the ground. The bottom one is the original data set.
13 And then the top one is actually a data set that we
14 collected at admittedly lower resolution, but because we're
15 not throwing out the data, you can actually see enough
16 resolution to see not only is there a house, but when you
17 zoom in there's two cars to the left of the house. There's
18 enough data to see that the car on the bottom is a Mustang,
19 like a late-vintage Mustang. Whereas in that bottom image
20 they've just thrown out so much that you lose all of that.

21 The third problem here is that to generate an
22 insight is a very multidisciplinary problem. And it takes
23 a lot of effort from a lot of very skilled people. And the
24 big lesson here is to make sure that when you deploy a
25 solution that all aspects of that value chain or analysis

1 chain are covered. And I would say this definitely extends
2 to the sensors experts. This is a very specialized skill
3 set to develop these sensors, but it extends to the gas ops
4 teams. And I think they play a very critical role as far
5 as forming how the technology gets operational-ized. And
6 then also how people respond to those insights.

7 Data collectors, I think have a very important
8 role to play as far as collecting not only good quality
9 data that is geo-registered well, all of this data is very
10 geospatial -- like it has a physical location and meaning
11 in the world. And it has to be referenced against all
12 sorts of other geospatial data. And so it's important to
13 get it in the right format. And then they have an
14 obligation to do that in an open-data format.

15 And then lastly your big data firms are really
16 needed to process, analyze, and extract these actual
17 results. And one of the big takeaways here is that it's
18 each of these groups are experts within their own domain,
19 but it will be very rare to find a group that touches all
20 of these at the same time. And so it's definitely
21 something to watch out for.

22 So getting into the analysis of this big data,
23 we've definitely seen a problem where a lot of analysis is
24 done for the sake of analysis. And this is a terrible
25 waste of people's time and money. And I think that the

1 takeaway here is that really the operational need should
2 guide and drive the data sites.

3 And another takeaway is that machine learning,
4 which is really the techniques that are used to analyze big
5 data, it's a very specialized skill set. If you look here
6 in the Silicon Valley most of the people that do this are
7 going off to work at Google and Facebook to serve up better
8 ads. And so there is I think a challenge to find the right
9 people that can do this sort of work. And the takeaway for
10 us is that machine learning, it's a really impressive
11 buzzword, but it's not magic and it's not a cure-all.

12 And so these solutions really do have to be
13 custom-tailored for the energy industry. I think it's very
14 important to note that when we talk about automation and
15 fixed algorithms they do not replace people. They're just
16 not that smart. What they're really good at is combing
17 through a very large quantity of data and then pointing out
18 specific findings for a person's review. And this gets
19 really important when we start looking into how you
20 visualize the data.

21 And so a recommendation and a lesson learned is
22 to vet people that are doing your analysis, both for their
23 analytical capabilities, but then also for their ability to
24 deliver operational insights.

25 And this is I think a really interesting example

1 from some our work. We get a lot of requests to do change
2 detection. A client will come and say, "I want to do
3 change detection to identify how things have changed." And
4 a lot of vendors are more than happy to do that.

5 And the image on the left is essentially a
6 changed section on a LIDAR survey done over the East Bay by
7 San Jose. This is about 100 square miles. And the
8 red/blue -- I know it doesn't mean a whole lot -- but
9 that's essentially changed, like it's really easy just to
10 do a change. But the problem is there's so much noise in
11 that. Like that doesn't mean anything.

12 And so if you look at that middle image this is
13 where we're running a whole different series of algorithms
14 to look through the changes and find things that are
15 actually worth an operator's attention. In this case,
16 looking for landslides and new housing and you can see two
17 of those call-outs. And I think this is a case where it's
18 really easy to generate a ton of data, but really you want
19 these algorithms to go through and find these things for
20 people to look at.

21 I think another interesting takeaway is we talk
22 about big data and how we can find all these problems, but
23 there's also an opportunity for the big data to reveal
24 where things are okay. Like for example, in that 100
25 square miles there is four things worth looking at, all

1 right? So I think there are a lot of potential negatives
2 that you want to be able to find, but let's not lose track
3 of the fact that it can also validate where things are
4 going well. And it I think provides a very strong
5 component for traceable and verifiable, complete record-
6 keeping and other socio-compliance obligations.

7 Last lesson, data visualization. So as I
8 mentioned before big data supports not supplants people.
9 And the implication of this is that people actually need to
10 look at your big data.

11 And within an operator you typically will have a
12 GIS group. And then you also have users that are not
13 ArcGIS experts. And they also potentially need to see a
14 lot of this data, but inside a different kind of framework.
15 And this is challenging, because data scientists will
16 typically want to abstract this into some sort of
17 mathematical fairyland that is completely meaningless in a
18 physical sense. And so there's a challenge here to bridge
19 that gap.

20 And so the lesson here is to ensure that big data
21 results are easily accessible to everybody. I think the
22 big data methods must accept your GIS as an input. There
23 is so much GIS data that an operator generates that becomes
24 extremely useful as an input. And then the big data
25 algorithms must output natively into ArcGIS, because you

1 don't want to disrupt operations. But then there is also a
2 need to visualize data in, I would say 4D, because methane
3 leak detection is a 4D problem. A plume (phonetic) is
4 three-dimensional, but it's also very time dependent and
5 this becomes very challenging.

6 And this is an example of a 3D visualization of
7 an excavation happening just outside a right-of-way in
8 Santa Cruz. On the left is the aerial image of that
9 excavation. On the right it's kind of hard to see in the
10 static 2D, but this is a 3D model being reconstructed. And
11 you can actually rotate this around. The bottom right
12 corner is the hole that has been excavated. Now imagine
13 this being a living thing that is evolving over time.

14 With methane leaks this is something that you
15 really do want to track is that time history in the
16 evolution of that entire system. So how you tell the story
17 visually becomes a very important part of closing this big
18 data.

19 Oh, out of time.

20 MR. KURTOVICH: So if anyone has any questions
21 please come up to the mic.

22 MR. O'CONNOR: Can I ask a question?

23 MR. KURTOVICH: Sure.

24 MR. O'CONNOR: Hi, this is Tim. The gentleman
25 from Enview, it seems that big data is going to be such a

1 complex undertaking for the analytical piece. It really
2 sort of will very quickly go beyond the capabilities of an
3 individual sort of company or like an operator or a utility
4 or something like that. So do you think you'd need this
5 sort of third-party framework to come in and do the
6 analysis? Or do you think utilities themselves can manage
7 these kinds of data sets from what you've seen?

8 MR. GUNAWARDANA: From what I've seen I think the
9 short answer is I haven't seen within the electric
10 transmission side. Within some of the gas operations side
11 I think they're challenged to find the right type of talent
12 to do that.

13 That said I think it's always possible for these
14 companies to develop that capability in-house. And I think
15 the important part when you collect this remote sensing
16 data is to make sure that the in-house teams can have
17 access to the data to develop their own lessons and
18 analyses. And this is why you don't want that proprietary,
19 walled-off data format that some vendors might collect,
20 because that completely precludes that possibility. And I
21 think it's of benefit to everybody if there's an open
22 competition for whoever can do the analysis the fastest,
23 cheapest, and most effectively.

24 MR. KURTOVICH: Okay. I'm going to ask a
25 question. In our SB 71 proceedings there was a working

1 group on best practices. And about two months ago there
2 was a paper we issued that summarized some of the findings
3 from this working group. And it included four principles
4 for methane leak abatement best practices. And one of
5 them, I thought was very emphatic and that was that
6 industry standards for safety and supplemental measures are
7 needed to meet the challenge of eliminating methane
8 emissions to the extent necessary to meet state goals.

9 And I was wondering if anyone on the panel knew
10 or was aware of any measures or initiatives for there to be
11 industry standards related to data and data utilization and
12 analysis? I mean, you have state agencies, federal
13 agencies that are working on this and developing it. But
14 has Alberta or any other industries come forward with
15 trying to standardize it, so what you have in California is
16 the same as you have in Texas or Colorado, back on that?

17 MR. DRIVER: So it's Keith. I can speak not from
18 the California experience, but otherwise is that I think we
19 would all be -- well, maybe not all of us, but a number of
20 us would be very surprised at how little data is kept in
21 the upstream sector, particularly year round. So they'll
22 know where the well sites are. And they'll have the sense
23 generally of what equipment is there.

24 But to do inventories of the number of pneumatics
25 or the number of flanges or the number of leaks, maybe at

1 gathering stations in some of the larger infrastructure.
2 But specifically at all the other distribution sites it's
3 just not there. And it hasn't been there, because there's
4 been no need for it. And its assets move so dynamically
5 among parties that having a data set of an asset you're not
6 going to own forever isn't useful. And so part of these
7 requests or data requests or otherwise are hitting or are
8 swapping blind.

9 An example would be in B.C. there was a push to
10 swap out all high-bleed devices. You could either swap
11 them out or can you can measure them continuously,
12 measuring continuously costs a lot more than swapping them
13 out, so people were quite concerned. Initially we had to
14 push back and say, "We can't do that. There's just too
15 many of them and frankly, we don't know where they are."

16 So to meet that objective, that rulemaking
17 strategy which makes sense of you must swap them out,
18 you're going to drive up the price and the cost without
19 getting any environmental good out of it. So we swapped to
20 a different approach. I think those fundamental gaps, how
21 do we create the data sets that we can then analyze, is
22 important.

23 MR. O'CONNOR: If I can answer that -- and I'd
24 like to actually ask Bob from PHMSA a question on this.
25 There's a big effort underway to try to understand the

1 emissions of loss in unaccounted for gas. And PHMSA has a
2 requirement to do so, to report that. But of course we
3 know that "lost and unaccounted for" is not just gas lost
4 to the atmosphere, it's gas that is changed in the pipes in
5 terms of volumes. There's a number of things: meter
6 errors, thefts, pressure differential changes. And there's
7 been a lot of talk about trying to develop some
8 standardized metrics for coming up with gas lost to
9 atmosphere.

10 Do you know of any movement underway there that's
11 by PHYMSA or by the industry to try to come up with some
12 lost and unaccounted for gas metrics that actually are
13 uniform and they can capture gas loss to the atmosphere?

14 MR. SMITH: Thanks for the question. We are
15 going to have rulemaking on the subject, so part of that I
16 would imagine there will be a discussion about what metrics
17 are going to be important for an operator from the
18 standpoint of changes to reporting requirements and stuff
19 like that.

20 Per the other question before I was kind of
21 hesitant, because I know the API, the American Petroleum
22 Institute, were looking at whether or not the standards
23 could be applied for leak detections systems. But that's
24 more about technology redundancies and overlap, so we don't
25 have a situation where a leak just progresses for years and

1 years; it's detected.

2 So those are the focuses there that not in the
3 context of really what we're talking about here. But I do
4 believe the rulemaking process that will begin with the
5 leak detection will get to some of the discussions with the
6 states as well as the metrics that are going to be
7 important, so stay tuned.

8 MS. SCHEEHLE: Hi, I had a question. So
9 Elizabeth Scheehle from ARB, really interesting
10 presentations and I'm still sort of chewing on the last
11 couple.

12 But I did have some questions for NETL and PHMSA
13 on the state participation efforts that are coming up. I
14 know Cynthia you had mentioned a lot of collaboration with
15 industry and all that. Are you going to invite some of the
16 states that have been working on these issues into that,
17 into some of the (indiscernible)?

18 And it's a same question on the pipeline, PHMSA
19 side, and just for the upcoming PHMSA LIDAR, when will that
20 rulemaking start?

21 MS. POWELL: First, yeah so within the current
22 flow of this out there, state participation is not a
23 requirement. That said we certainly recognize the
24 importance of engagement. And we will be reaching out with
25 workshops and things like that to try to be as broadly

1 engaging as we can with interested states.

2 MR. SMITH: Our engagement with the states is
3 significant, both individually with the states as well as
4 through the National Association of Pipeline Safety
5 Representatives, the trade organization representing them.
6 And it can be from anything from working to better improve
7 state programs, whether it be in excavation damage programs
8 or integrity management programs.

9 We participate in each other's events throughout
10 the year. From the research side they're always invited to
11 help us review submissions. They're a part of our R&D
12 forums to say, "Here is our national challenges for the
13 states for research needs." And so we have a significant
14 role for the states to play in a number of programs at
15 PHMSA.

16 MR. HOU: Hi, Yu Hou from the Energy Commission.
17 I have a question for San for the big data.

18 The electricity system I can see both the power
19 lines, especially the transmission lines, they are above
20 ground where you can see it. You can fly over them. But
21 for the natural gas there are much more structures or
22 infrastructures that are underground. And I just kind of
23 am wondering what are your thoughts on that in terms of
24 collecting data?

25 MR. GUNAWARDANA: Yeah. No, thank you. That's a

1 great question. I think it's very apt. The infrastructure
2 for a pipeline is definitely harder to observe and I think
3 that puts a bigger burden on the types of sensors and the
4 need to collect data, so it's a harder challenge.

5 We see a lot of operators doing some pretty
6 amazing stuff out there. You think about the leak
7 detection you are sampling essentially the above-ground
8 products of that underground leak. Where it gets really
9 tricky is being able to back-calculate that to the point of
10 origin. And so I think this once again it actually becomes
11 a bigger data problem for methane leak detection on the
12 pipeline side. And the fact that you can see the
13 infrastructure directly complicates it, but isn't a
14 showstopper.

15 MR. SMITH: If I can add to that comment, I think
16 that's a key point. We see these maps of pipeline or leak
17 areas within like an urban area. Those are leak paths,
18 those aren't necessarily the exact location of the leaks.
19 There's a number of factors that govern where the natural
20 gas, geo-methane, is escaping from.

21 So it could be several very small leaks
22 aggregating together coming out through a manhole. It
23 could be the strata of the earth, the times of year, the
24 operating pressures. We have gas migration issues where
25 sometimes through drought seasons we have an annulus that

1 occurs between the pipe and the soil layer. And gas is
2 able to migrate for upwards of miles before it's finally
3 released to the environment, so there's a number of more
4 factors. That's why it's key to work with the pipeline
5 operators on action plans about what they actually need to
6 have is inputs to develop remediation programs for these
7 leaks.

8 MR. KURTOVICH: Any more questions? Seeing none
9 I guess we'll adjourn and then re-convene at 1:15.

10 MS. KOZAWA: We have ended a little early, but I
11 would like everyone to be sure to take advantage of talking
12 vendors outside if you haven't already. And we do have
13 vehicles in the courtyard being displayed currently.

14 So we'll actually reconvene for the panel session
15 at 12:30. It's not even 11:00 right now, so come back here
16 at 12:30 for the first panel session.

17 Thanks so much.

18 (Off the record at 10:40 a.m.)

19 (On the record at 12:35 p.m.)

20 MS. KOZAWA: Good afternoon and welcome back.
21 Oh, I dropped the microphone.

22 Welcome back to Session 5, our regulatory panel
23 is about to begin, to moderate this panel today with the
24 Division Chief for the Industrial Strategies Division,
25 Floyd Vergara. Floyd?

1 MR. VERGARA: Thank you, Kathleen.

2 Welcome back everybody. I hope you enjoyed your
3 lunch and the really nice weather we're having especially
4 relative to the triple digits we've had over the last
5 couple of days.

6 I was listening in on this morning's session, I
7 thought it was really informative and I'm looking forward
8 to an informative session on the regulatory side as well.
9 I've been at the Board for 28 years doing nothing, but
10 regulations. So I'm looking forward to hearing all the
11 different perspectives on directions with regard to
12 regulations and how to reduce methane emissions both in
13 California and outside of California.

14 So with me today we have a distinguished group of
15 panelists. Introducing from my life Elizabeth Scheehle,
16 she works for me at the Air Board. She's the Chief of the
17 Oil and Gas and GHG Mitigation Branch.

18 To her left is Art O'Donnell from our sister
19 agency at the California Public Utilities Commission.

20 To his left is Trina Martynowicz from USEPA
21 Region 9. To her left is Brady Van Engelen, he's from the
22 -- oh I'm sorry -- from DOGGR. I think most of you know
23 DOGGR, but for those who don't it's the Division of Oil,
24 Gas and Geothermal Resources at the Department of
25 Conservation.

1 And then finally, our last speaker is Laurie ten
2 Hope, Deputy Director for Research and Development at the
3 California Energy Commission.

4 So I'm going to open it up by asking the
5 panelists one by one to take a little bit of time to tell
6 us about their programs, what's going on, and give us the
7 lay of the land.

8 And I'll start with Elizabeth.

9 MS. SCHEEHLE: Thanks, Floyd.

10 And thanks everybody here, I think this has been
11 a really interesting and useful symposium and is very
12 timely for us as we're working on our oil and gas
13 regulation and working with the PUC on what they're doing
14 as well. I'm just going to spend a few minutes, talk about
15 the oil and gas regulation that we just put out last week
16 and some of the other work that we're doing.

17 So we put out a regulation last week and it
18 covers kind of the upstream portion as well as underground
19 storage and processing and transmission compressor
20 stations. And so what that looks at is reducing emissions
21 from tanks, compressors, pneumatic devices and components.

22 And one important thing that kind of you heard
23 this throughout some of the discussions. We did
24 incorporate high leaker factors for some of those, for the
25 components where possible, because we did see this trend,

1 this fat tail trend happening and wanted to make sure that
2 we accounted for that. So that was something we found
3 important.

4 And I also wanted to emphasize that this is built
5 upon decades of work that's been happening at the local air
6 districts on ozone issues. So there are VOC emissions from
7 the oil and gas industry as well. And so we worked with
8 the districts very closely, what they've put in place
9 toward the VOC emissions, and then expanded that to look at
10 kind of the non-VOC sources, the primarily methane sources.
11 So that has been very useful.

12 And I think we actually start from a different
13 baseline than a lot of other places might. We actually
14 have lower emissions than maybe some other oil and gas
15 producing regions.

16 I also wanted to mention -- I'll let Art really
17 dive into this -- but we are working closely with the
18 Public Utilities Commission on their work on reducing
19 emissions from the transmission and distribution side.

20 So the combination of this, both of those
21 regulations, the upstream and the downstream we really are
22 looking at covering the entire infrastructure within the
23 state. And we are anticipating that to look at basically a
24 40 or 45 percent reduction. You've seen that number before
25 in different presentations. And what's left after that is

1 really accounting for what we import as well in the
2 emissions associated with that since 90 percent of the
3 natural gas we consume is imported.

4 I also wanted to mention that we are covering all
5 of the infrastructure, but we are also looking at, "Is
6 there anything we are missing?" And I think some of what
7 you saw, are things that we're thinking about in terms of
8 abandoned wells and are there things beyond the meter that
9 we need to be thinking about next?

10 So finally, I'll also just say we're also
11 interested in looking at the co-benefits from these
12 regulations, reductions and talks in making sure there are
13 no increases in other pollutants as well. So that just
14 kind of gives an overview of what we're working on at ARB
15 on the oil and gas side. And I'll turn it over to Art or
16 Floyd if you want to give a --

17 MR. VERGARA: No, thanks Elizabeth.

18 And I think what we'll do here is we'll let all
19 the panelists go through their talking points. And then
20 we'll either open it up to the audience for questions or I
21 have some questions myself I could pose as well.

22 So Art, why don't you go ahead and go through
23 your presentation?

24 MR. O'DONNELL: Okay. Good afternoon, everyone.
25 Okay, one more time, good afternoon everyone.

1 AUDIENCE: Good afternoon.

2 MR. O'DONNELL: Thank you. Let's get the energy
3 level back up here. (Laughter.)

4 I am Arthur O'Donnell. I am a Supervisor in the
5 Risk Assessment and Safety Advisory Section of the Safety
6 and Enforcement Division at the California Public Utilities
7 Commission. I am the purveyor of just in time regulation,
8 as you can tell as I walked in the door after we started,
9 so my apologies to fellow panelists. We hit some heavy
10 traffic outside of Davis for no apparent reason.

11 I say "just in time regulation," because
12 sometimes it's really difficult to keep up with events.
13 And one of our current proceedings that we're working with
14 Elizabeth and the staff at ARB on is a prime example of
15 that. In that it was responding to legislation, SB 1371,
16 from Senator Leno which directed the Public Utilities
17 Commission -- working cooperatively with the ARB -- to do
18 several things.

19 But mostly it was to get a handle on what the
20 real situation is with leaks and emissions of natural gas.
21 But in particular methane component of natural gas -- which
22 as you know is the major component of the natural gas that
23 gets delivered through our system -- to develop best
24 practices for the detection, the quantification, and the
25 reduction of such leaks and to do this on a regular basis,

1 and to build those new understandings into our rules,
2 policies, and regulations covering the gas industry.

3 Now the Public Utilities Commission has a pretty
4 defined regulatory authority over this, in that acting on
5 behalf of the federal government the PHMSA Group -- which
6 is the Pipeline Hazardous Materials Administration, safety
7 administration -- we are the agents of federal policy for
8 auditing, inspecting, making sure that the pipeline system,
9 everything above ground is up to snuff, meets standards,
10 and does not blow up every now and again.

11 All right, we also have jurisdiction over when
12 things that do blow up, like through excavations or dig-
13 ins.

14 And during the pendency of this particular
15 proceeding, we had Aliso Canyon, which started last
16 October. And the leaks there lasted through February,
17 which really not only upended our sense of our
18 jurisdiction, because our friends at DOGGR had primary
19 jurisdiction over that component of the storage system, and
20 yet everyone got called into this emergency, all right? So
21 that's one thing.

22 The second is that because of that, now agencies
23 up and down the line from the federal government on down to
24 the state are ratcheting up their regulations. And so
25 while we thought we were being cutting edge with some of

1 the things we were doing in the 1371 proceeding, we're
2 actually catching up in some regards. And the newest
3 regulations from ARB that impacts the storage component and
4 some of the other components of the system are a good
5 reference point, because we were moving in a direction and
6 now we have to go really fast.

7 I'll close right here with one of the big
8 important factors of SB 1371, which was really for the
9 first time -- and I'm not sure that all our friends in the
10 gas industry have quite gotten it yet -- we are treating
11 methane releases as a safety hazard, as a hazard to the
12 environment, a health problem.

13 Our jurisdiction, under PHMSA is largely about
14 safety, because everything gets determined or gets
15 categorized by, "Is this hazardous to people or property?"
16 All right, that's category one. Category two is, "Could it
17 be if we let it go, right?" And so you schedule that for
18 repair. And three, is leaks on the system that are not
19 considered hazardous under that régime. And those would be
20 category three leaks, because they're far away from
21 properties or they're of a minor volume. And so the gas
22 companies generally have, "Watch those, schedule them for
23 repairs if they seem to be getting worse." Or sometimes
24 letting them go on and on and on.

25 Part of this proceeding was to actually get all

1 the gas companies to report on their leaks. And I'll say
2 that we were surprised at one major finding from our first
3 round of surveys -- which happened last May -- was that
4 while we thought that the problem with leaks and emissions
5 was in these category three leaks on the gas pipeline
6 system and other components, really what we found were
7 there were uncategorized leaks largely from vented
8 emissions during maintenance procedures at gas facilities.
9 And to our surprise "other," the vast other category which
10 was largely comprised of the threaded fittings between the
11 riser that comes up from the distribution part of the gas
12 system to the meter at the household.

13 Now a caveat, these are estimated emissions, all
14 right? We don't really have a really good handle on what
15 the actual emissions profile is, but using the emission
16 factors that ARB developed and that the utilities routinely
17 use, we determined that this could be almost half of the
18 total emissions profile that we want to do something about.

19 So when we came out with best practices in March,
20 we put a heavy emphasis on those two components as well as
21 things like increasing the schedule for repairing the
22 leaks, category twos or threes. And a lot of other best
23 practices that I can talk about in response to questions.
24 But that's generally the framework around which we're
25 working.

1 One more just in time issue is that the
2 Legislature is in session. And if you've been following
3 them at all, you know that there are literally a dozen
4 different bills that somehow impact the gas system, because
5 of Aliso Canyon. And we're trying to not only follow them
6 as they change on an almost every day basis, but also
7 figure out what that's going to mean for our regulation,
8 for ARB's regulation, for DOGGR's regulation, for your
9 business.

10 So I'll leave you with that and turn it on over
11 to Trina.

12 MS. MARTYNOWICZ: Hi, Trina Martynowicz, U. S.
13 Environmental Protection Agency.

14 So back in March of 2014, Obama announced his
15 goal to be reducing methane emissions 40 to 45 percent,
16 primarily utilizing the Clean Air Act. There are other
17 federal statutes as well. There were various white papers
18 that were released that year.

19 And last August, we proposed a few different
20 rules to cut methane as well as VOCs, both from the oil and
21 natural gas industry and clarifying various air permit
22 requirements. About three weeks ago, mid-May, we finalized
23 those rules as you may be aware as well as proposed an
24 information collection request.

25 The three rules that were finalized were for new

1 modified sources. During that public comment period,
2 received over 900,000 public comments. And I'm sure a lot
3 of you in the room probably helped provide those comments,
4 so thank you for taking that time to do so. We
5 incorporated a good number of them, which I'm happy to
6 highlight.

7 From these three rules, we anticipate reducing
8 over 510,000 short tons of methane by 2025 or 11 million
9 metric tons of carbon dioxide. The climate benefits are
10 anticipated to reach \$690 million by 2025. Besides
11 reducing methane, of course we'll be reducing VOCs, an
12 anticipated 210 tons. And then various air toxics, 3,900
13 tons. I'm happy to highlight these three rules. And as I
14 mentioned, these are for new modified or reconstructed oil
15 and gas facilities.

16 We first belt upon our 2012 VOC emission rules.
17 For these sources, we are setting methane limits. We're
18 also looking at having a fixed schedule for monitoring
19 leaks. And there is a year for initial leak survey
20 detection. We also are allowing facilities to take a
21 variety of approaches for detecting leaks, including using
22 method 21, repairing a threshold of 500 appm. And then
23 also facilities can use emerging or innovative ways to
24 detect these leaks per EPA approval.

25 For the new source determination rule, we're

1 clarifying our air permitting rules, looking at clarifying
2 the Prevention of Significant Determination, PSD, on the
3 non-attainment new source review, and the Title 5 operating
4 permits. These rules are defining what adjacent equipment
5 and activities are -- essentially if there's different
6 types of equipment that are on the same site that share
7 common equipment and that are within a quarter mile from
8 one another.

9 We also finalized the Federal Implementation
10 Plan, or FIP, for Indian country for minor new source
11 review. This is just really streamlining the permit
12 process for those facilities that are on Indian country or
13 in tribal lands beginning in October of this year. The FIP
14 also, I should mention especially being here in California,
15 does not apply to those tribes that are nonattainment
16 areas. So if a tribe is in a nonattainment area, they're
17 still going to need a site-specific permit or if a
18 reservation already has a FIP, they're able to use that.

19 We will be issuing control technique guide lines
20 to be reducing VOCs from existing sources in nonattainment
21 areas. And then as I mentioned, we are issued a draft,
22 kind of draft survey, for information collection requests.
23 So this essentially is for existing facilities. That
24 comment period is open, so I suggest you please -- we're
25 requesting everyone to provide comments, which this ICR

1 request we're anticipating will help create our eventual
2 regulations for existing sources.

3 I'm happy to talk maybe a little later about EPA
4 working with a variety of states, of course the State of
5 California, on harmonizing our final rules with our
6 proposed rules. BLM is also having proposed rules coming
7 down the pike. And then we're also doing a bit kind of
8 more broadly on methane that I'm also happy to talk about a
9 lot of partnerships, tools, resources, funding
10 opportunities, etcetera. Thanks.

11 MR. VERGARA: Great. Thanks, Trina.

12 Brady, if you could talk to us about what's going
13 on with DOGGR?

14 MR. VAN ENGELEN: Sure. Thank you. My name's
15 Brady Van Engelen from the Division of Oil and Gas and
16 Geothermal Resources. We're the agency that oversees the
17 oil and gas production for the state.

18 Beginning last fall, we had started to revise our
19 underground injection control regulations. Obviously in
20 late October that process was derailed by Aliso Canyon.
21 And since then we've focused our energies on gas storage
22 with UIC still being a component that'll be worked on at a
23 later date. But for now, given that the gas storage
24 emergency regulations went into place on February 5th our
25 energies are focused primarily on creating a regulatory --

1 modernized regulatory framework for gas storage.

2 The broader approach that we're looking at here
3 is trying to create a proactive environment rather than a
4 detective environment, if you will. The regs as they
5 currently -- or I guess you could say as they were written
6 prior to the emergency regulations, require a lot of
7 reactive testing and response by the operators. We'd like
8 to move towards more of an environmental where the testing
9 informs the engineers on the ground, who then follow up
10 with the operators and inform them of what steps need to be
11 taken for each.

12 Well, mainly what we're trying to do is reflect
13 modern technological advances, advancements -- well
14 construction standards up to date as well too. Leak
15 detection as (indiscernible) we're working on very closely
16 in consultation with the Air Resources Board. And a very
17 large component of our gas storage regulations will be the
18 risk management plans. And we're working on those very
19 closely with the National Labs who played a key role at
20 Aliso Canyon and continue to work with us today and they're
21 a valuable asset for us.

22 The risk management plans are primarily devised
23 to respect the fact that all these wells are -- all these
24 fields are in different -- the geology's different for each
25 field and essentially each well too, so the operators need

1 to take that into account. If that's taken into account
2 and reviewed by the engineers at that point then a response
3 to go forward could be provided.

4 We're not there yet. It's really something
5 publicly, but we're working diligently to get something
6 out. I'm happy to answer broader questions, but again
7 those are still in the draft process.

8 MR. VERGARA: Great. Thanks, Brady.

9 And Laurie if you could take up the activities of
10 the Energy Commission, please?

11 MS. TEN HOPE: Sure.

12 So the Energy Commission is really working in
13 concert with our sister agencies on several aspects, so
14 from sort of a policy prospective and a nuts and bolts
15 perspective. And I'll sort of start backwards with some of
16 the nuts and bolts who the last couple of days have been
17 spent on methane detection, monitoring, assessment
18 abatement. And we're very much engaged in those activities
19 from a research perspective.

20 You heard presentations from some of the
21 researchers that are funded by the Energy Commission and Yu
22 Hou who presented for the Energy Commission and will
23 continue supporting research that gives us a better
24 assessment of where the super-emitters are, how to detect
25 them more cost effectively, what strategies there are to

1 monitor and mitigate. We work closely with the Air Board
2 on research. We want to collect research with a common
3 methodology that the Air Board can utilize as its looking
4 for what regulations make sense.

5 For example, we have a project where we'll be
6 looking for super emitters around the state. And our
7 research is focused on the natural gas infrastructure. And
8 the Air Board will be focused on other sources, but will
9 use the same contractor or the same sub and develop a
10 common methodology. So what's collected from one source is
11 comparable to another source.

12 I think we've heard discussions that we have
13 indications that leakage might be higher in buildings than
14 we thought, so let's go take a look at that. We're
15 conducting research in residential and commercial buildings
16 to increase the sample size of what kind of leakage there
17 is behind the meter.

18 We're also looking in a complementary area of
19 pipeline safety, so some of these leaks -- they don't lead
20 to catastrophic health issues in the short run. I'm
21 talking about explosion kind of health issues. So we also
22 focused on work to support the CPUC and the utilities on
23 how to more cost effectively assess corrosion and other
24 types of issues with the natural gas pipelines, so that
25 they can -- leaks and issues can be found more quickly and

1 do a better risk assessment. Right now, it's expensive and
2 it's challenging.

3 We're also planning to do research on abandoned
4 wells and the impact of ground subsidence on wells, find
5 them. Also DOGGR is helping with providing different
6 generations and whether wells have been capped or not and
7 where they are, so that we can assess different generations
8 and what the leakage patterns are, given different types of
9 capping strategies.

10 I mean, there's a lot that we're planning to do
11 in the research area to help support leakage detection.
12 But I think the question put to the panel was also broader
13 in terms the role of natural gas going forward. And I
14 think there are a lot of questions. We certainly know that
15 the more we can transition away from natural gas, that's an
16 obvious mission reduction strategy, but how to do that in
17 what sectors and when, there are a lot analytical questions
18 to be addressed.

19 Right now with the electricity mix that we have,
20 it doesn't necessarily make sense to switch to natural gas,
21 but as you are more and more electrified by renewable
22 sources than your emission and cost profile changes. So at
23 what point should we be pushing electrification of
24 appliances versus more efficient appliances. But that's an
25 analytical question that the Energy Commission plans to

1 tackle along with the ISO and the CPUC and the assessments
2 that are planned for the 2016 and 2017 IEPR, probably more
3 the 2017 and beyond, to really look at the questions of the
4 role of natural gas going forward.

5 In the short term the questions that the Energy
6 Commission will be looking at from a policy prospective are
7 really around reliability, so given Aliso Canyon and the
8 dependence that the state had on natural gas storage
9 facility what kinds of strategies can be put in place to
10 mitigate reliability issues this summer, this winter, and
11 next summer.

12 So that's the short term focus. And then the
13 longer term focus would be look at much deeper into the
14 challenges of electrification and transitioning from
15 natural gas.

16 MR. VERGARA: Great. Thank you, Laurie. It
17 sounds like we're all very busy with activities related to
18 methane. So it sounds like there's a lot of things to keep
19 track of.

20 Before I open it up to the audience for questions
21 I have a couple of questions myself and I'd like to open it
22 up to the panel members to address it. I'm going to
23 address this to the panel at large, so any of you can take
24 it or all of you can take it.

25 So Aliso Canyon was mentioned earlier, and

1 obviously it was a big wakeup call for everybody involved.
2 I'd like to know if there were any specific lessons
3 learned, takeaways from Aliso Canyon, that inform what we
4 are doing or what we should be doing in the future. So is
5 there -- and related to that is, you know, what can we
6 learn from Aliso Canyon to prevent another similar incident
7 as well?

8 So I'll open it up to the panelists to take that
9 up. Whatever order you guys want to do. We'll start to my
10 left, since she works for me, so. (Laughter.)

11 MS. SCHEEHLE: Thanks?

12 I can start out by talking about what we have
13 done. I didn't really mention it in my opening remarks,
14 but we have, based off of what happened at Aliso Canyon,
15 we'd always in the oil and gas reg had storage in there and
16 had the storage facilities being subject to the leak
17 detection repair requirements, which are sort of a
18 quarterly requirement that folks have to go out to their
19 facility and detect leaks and fix them within a certain
20 timeframe.

21 What we've done in response and actually working
22 with DOGGR on this, they have as part of their emergency
23 regulations a daily leak detection kind of protocol that
24 facilities follow. They submit it and then it gets
25 approved by them and ARB is working with DOGGR on that.

1 And we actually are incorporating that into our
2 regulations, kind of taking on the air portion of that,
3 looking at the daily monitoring as well as continuous
4 ambient monitoring, so that if there are leaks that we find
5 them quickly. And that may enable fixing them quickly or
6 before they become worse, so that's part of what we've
7 done.

8 We've also done some clarifications within the
9 reg to make sure that things that are leaks downhole are
10 considered leaks above ground as well, so from the ARB
11 perspective that's some of what we've done.

12 We are looking to what happened with the root
13 analysis. What comes out of that and see if there's
14 anything additional, obviously working with our sister
15 agencies on that on who's the appropriate person to take
16 that on. But if there is something additional that we need
17 to do, is consider it at that time.

18 MR. O'DONNELL: I have four lessons and two of
19 them will get me in trouble with my bosses, so Maria you
20 just keep your mouth shut. (Laughter.)

21 The first is that it told us once again. Every
22 incident tells us this. How fragile the system really is.
23 We have an aging infrastructure. Electricity, natural gas,
24 just about anything that we rely on; they all are eligible
25 for AARP membership, pretty much.

1 Also, this teaches how interconnected our systems
2 are. And so we have to think broader than the risks to the
3 gas system or the risks to storage and the impacts that
4 that has on electricity. Currently, we're dealing with the
5 possibility -- I'm just saying possibility -- that under
6 peak circumstances this summer there may not be enough gas,
7 because this major storage facility is unavailable, to
8 power generators in Southern California. And so that
9 causes a whole host of subsidiary policies to be put into
10 effect on a somewhat expedited basis, sometimes without the
11 benefit of due process, right? That's what happens anyway.

12 So one of the good lessons is that you get your
13 coordination in advance. That you work with the other
14 agencies to develop the mechanisms for sharing information
15 so that you have that on the shelf. And we kind of like
16 had to try and keep up with that.

17 But I'll say, for instance, that when we started
18 the 1371 proceeding, the first thing that I ended up doing
19 was shepherding a Memorandum of Understanding between our
20 agency and the ARB in order to share what otherwise would
21 be considered confidential information from the gas
22 companies. And we're now affecting similar MOUs with
23 DOGGR, with OES, with the Energy Commission. I just got an
24 MOU signed by our executive directors with the Energy
25 Commission for a whole other purpose. But when we have

1 those in effect, response is a lot faster.

2 The second is that risk management, and its
3 proper role in regulation, is really something that we have
4 to pay attention to.

5 And you've heard it mentioned a few times here.
6 In our case, one of the lessons that we had to learn is our
7 major function as an economic regulator is to approve
8 utility requests for money right, through general rate
9 cases. And there was in fact, in the Southern California
10 Gas general rate case that is now coming to a conclusion
11 but filed initially in 2014, a section about storage
12 infrastructure, the aging storage infrastructure, and the
13 proposal that SoCalGas had for a six year program to
14 essentially inspect every component part of their system,
15 their storage system, repair what needed to be done,
16 upgrade the rest and figure out what to do from there.

17 A general rate case is not really the place to do
18 that, if three months later the system is going to fall
19 apart, all right? So we learned that we have to one, read
20 between the lines a little bit more. And be more proactive
21 and suggest to our utility friends that if they see
22 something that they think is really going to be a problem,
23 take it out of the GRC and give it to us in a format that
24 we can deal with much more rapidly.

25 Now I'm not going to fault them for this. They

1 came to us with a proactive plan that on paper looked
2 pretty good, but in retrospect, what do you hear? You hear
3 from the Legislature. You hear from the Governor. You
4 hear from the media that, "Oh, they told you in 2014 that
5 their system was falling apart and you didn't do anything
6 about it."

7 Well, we in fact were doing something about it,
8 but in a slow procedural manner which was not appropriate
9 for the particular circumstance, but 20-20 hindsight,
10 you've heard of that.

11 All right, the final lesson is that you have to,
12 as an agency as regulators, accept responsibility even if
13 it's not your responsibility, right? And because the
14 Legislature is in the habit of beating up on the Public
15 Utilities Commission and has been since the San Bruno
16 explosion -- and before that really -- they came down hard
17 on us. And it did not do us any good to say, "But DOGGR,
18 DOGGR, those guys over there," because that just doesn't
19 work, all right?

20 And so we had to kind of like own up to it. Make
21 it part of our responsibility, in coordination with DOGGR,
22 in coordination with the Office of Emergency Services, in
23 coordination with ARB and everybody else that got involved.
24 And there were many, many telephone calls in order to
25 figure out how to do it. So those were lessons that we

1 learned at the PUC.

2 MS. MARTYNOWICZ: So EPA is working on actually
3 our recommendations, so I guess Floyd's question is stay
4 tuned for the fall.

5 We, I think, the NETL presentation mentioned
6 earlier today that there's a federal task force examining
7 the incident. The White House is involved, the Pipeline
8 Hazardous Safety Administration, Health and Human Services,
9 Interior, Commerce, FERC, NOAA and EPA, DOE.

10 The task force was charged to submit a final
11 report in the fall, six months, where specific
12 recommendations will be provided that could potentially
13 apply to around 400 natural gas storage facilities
14 throughout the nation and potential regulations to follow
15 that. This report's going to include analysis and a
16 conclusion of looking at the cause of the leak, measures
17 taken to stop the leak, the impacts of the health, safety,
18 environment and economy of the residents and property
19 around the area, and then just an overall analysis of the
20 response.

21 We're working with a variety of state agencies
22 here, so thank you folks for working with us on this. And
23 there's a variety of work groups that are breaking down
24 these activities in infrastructure and storage and safety,
25 looking at how the leak occurred and prevention.

1 And then the EPA is overseeing -- my office out
2 of San Francisco, is overseeing the Public Health and
3 Environmental Work Group and coordinating the communication
4 on that. We're looking at post-leak, so looking at the
5 health and safety of the residents, the ambient air
6 monitoring and communications.

7 So for example did we use the right monitors?
8 Did we test for the right pollutants? How is that data
9 utilized? How is that communicated? What was the process
10 of testing indoor health, for example? And then how was
11 that communicated publicly and what decisions were made and
12 were those the right decisions and the right process, so
13 for example moving the residents out of their homes.

14 And then looking at more of the emission sides,
15 the greenhouse gas emissions, the quantification, was that
16 accurate, and then the future activities and proposals for
17 mitigation.

18 That report, as I mentioned, is going to be
19 coming out in the fall. And yeah, of course, it's all
20 hindsight, right? It's all could-of, should-of, would-of,
21 and that's really not the focus of this report. That's not
22 the purpose. It's not finger pointing, but really looking
23 at what were those good decisions? What lessons were
24 learned? And then what recommendations are going to be
25 transferrable?

1 And then I should also mention that our
2 Information Collection Request looking at the existing
3 facilities is going to examine underground storage tanks
4 and facilities, which of course EPA is not currently
5 regulating.

6 MR. VAN ENGELEN: So I guess the easy out here is
7 today that we have -- we're working with the PUC on a joint
8 investigation, which will provide some lessons learned.
9 And also our Monitoring and Compliance Unit within the
10 Division is also conducting their own investigation, which
11 will be more specific on the well itself, which provides
12 some lessons learned.

13 But from a broader prospective the Division
14 historically has looked at gas storage as a subset of UIC.
15 And we quickly realized that we couldn't meet our mandates
16 required of us if we continued to do that. It's grown into
17 its own program, so I guess that's probably the bigger
18 lesson learned from the Division. But the timing on that,
19 getting back to the investigations, the timing will be
20 largely determined on the testing, which is underway right
21 now. And I don't have a great timeline on that.

22 MS. TEN HOPE: I'd say too the lessons learned
23 kind of parallel a couple of things that Arthur mentioned
24 and a third that's a little bit different.

25 But you were mentioning how fragile the system

1 is. And I think a lot of the strategies that we are
2 putting in place can build in flexibility to the system and
3 helps with that fragility. We still need to replace
4 infrastructure, but the strategies with renewables demand
5 response, storage and building up more of renewables and
6 strategies, more on the distribution and end use level,
7 does build up some flexibilities so you're not quite so
8 dependent on large utility-scale infrastructure. And it
9 allows deploying new strategies when something like this
10 happens.

11 One of the other ones that Arthur mentioned was
12 collaboration among agencies. And it probably sounds kind
13 of boring, but it really works. All the state agencies, in
14 particular, at this table along with the ISO met regularly,
15 weekly if not daily, with the Aliso Canyon crisis. And
16 then on an ongoing basis for, "What do we do mid and long
17 term to address these issues?" And when you're all working
18 in concert to the same goal, you actually get somewhere, so
19 that -- it's I think been really important.

20 And the third lesson learned was, we had a
21 research project that was looking at whether an
22 instrumented aircraft could measure and detect leakages
23 from the gas system and be useful in finding some of the
24 large emitters. And it sure was. We were able to deploy
25 it to Aliso Canyon and take measurements and that was some

1 of the early numbers that were coming in about really what
2 the scale of the release was. And so I think that
3 validated the research and also the value of a research
4 aircraft in that situation.

5 MR. VERGARA: Great, thank you.

6 Those are all great insights and lessons learned.
7 I think we can all appreciate the importance of Aliso
8 Canyon in terms of informing our future activities.

9 I'm going to open it up to the audience at this
10 point. Anyone have any questions? We do have microphones
11 that can be brought to you, just raise your hand if you
12 have a question.

13 (No audible response.)

14 No questions? Okay. Well, I will entertain you
15 with more questions. All right, I'm going to ask one and
16 answer it to the extent you're comfortable. I'm not going
17 to try to put anybody on the spot, here.

18 But natural gas in California, I think about 10
19 percent of it is produced in-state and 90 percent of it is
20 imported from out of state. And as much as people refer to
21 California as kind of an island in itself, we all in
22 California, at least at the regulatory stage, recognize
23 that we can't solve the world's problems by ourselves.

24 Methane certainly is a global climate issue and
25 given that 90 percent of the natural gas is imported from

1 other states, the question I would pose to the folks here,
2 and again I will open it up to the entire panel, is given
3 that most of the natural gas comes in to California from
4 outside of the state, what are the things that California
5 can do as a state to reduce methane emissions from the
6 national natural gas production and transmission system?

7 I know there are some thoughts going around, but
8 perhaps if you could share some of your thinking from the
9 regulatory agency standpoint. And even though this is a
10 regulatory panel I would open up the question to include
11 both regulations and non-regulatory policy instruments as
12 well.

13 MS. SCHEEHLE: I can start out again. I think
14 this is a really important component. As you said, 90
15 percent of our natural gas is imported and we have
16 developed a good system within California to get at the
17 emissions from both production, transmission, distribution.

18 I think one thing we've considered when
19 developing the regulations is how can those be exportable?
20 So I think that's part of it is, are these things that
21 other states can do?

22 On the production side we've taken what's been
23 done in the districts, we've looked at other states, and
24 what's being done federally. And looked at how we can make
25 this something that other places can do as well. And

1 that's a consideration when we're looking at the
2 transmission and distribution side as well. I think that's
3 even more sort of cutting edge in terms of looking at
4 methane from that sector.

5 And we're looking into more what are the
6 emissions associated with that? So we have a good sense
7 from EPA on kind of the national emissions, but what
8 actually comes in to California from the different basins.
9 And that's sort of the life cycle model that we talked
10 about and getting a sense of that. But and then watching
11 actually what EPA is doing, the new source performance
12 standards are important, but those do just impact the new
13 and modified sources. So seeing what happens for the
14 existing sources, does that get to the significant
15 reductions we need when considering the emissions that are
16 associated with what we use here. Or is there something
17 additional that we need to do?

18 I mean when you looked at -- in going over Roman
19 Alvarez's figures earlier about what this leakage
20 translates to into coal plants. I mean, that's a
21 significant number and looking at that, I think that is
22 something we need to address. How specifically we do it, I
23 think we're still thinking about, but one thing is the
24 exportability and looking at what's going on, on the
25 federal level.

1 MS. MARTYNOWICZ: Yeah, I mentioned EPA's rules.

2 I also definitely want to mention other methane
3 sources and renewable natural gas. The EPA has always been
4 a huge proponent of renewable natural gas. And we have a
5 variety of partnership programs that you probably have
6 heard of some of them looking at landfills, dairies, waste
7 water treatment facilities, etcetera.

8 So we provide different tools and resources
9 essentially to help bio-methane production from these
10 different sources. So if it's here in California, I think
11 there's still a huge opportunity. And I know with Aliso
12 Canyon and some mitigation activities there'll be some
13 additional resources as well as under the short-lived
14 climate pollutant strategies. So I think applauding the
15 state on that strategy and really just trying to focus more
16 on let's get more renewable natural gas. So I think
17 there's a lot of opportunity there.

18 And then yeah, we'll see with the EPA's
19 Information Collection Request, like you said, for existing
20 facilities, which I think we all know probably is not --the
21 proposed rules if definitely not final rules are going to
22 occur before November. So we'll see.

23 MR. VAN ENGELEN: So on the gas storage side I
24 guess more of on a well-by-well basis, a much more
25 aggressive testing regime, and it has proven to be

1 beneficial to this point. You know, there have been other
2 fields where come to bear that their wells (indiscernible)
3 and so that testing regime has been effective in the
4 limited scope that it's been used to date. Obviously,
5 there would be some other components to, that getting back
6 to risk management and detection, but those are the primary
7 components that we look at.

8 MR. O'DONNELL: All right, if I might, I'm going
9 to take off my regulatory hat and hearken back to my 30
10 years as a journalist who covered the energy business,
11 largely in California, but also for national entities that
12 cared a lot about California.

13 And the biggest and best thing that California
14 can do is be a role model for the rest of the country. And
15 we have done this again and again, in many areas of energy
16 policy. In particular on the environmental side, with the
17 introduction of selective catalytic reduction equipment on
18 power plants in Southern California, in order to
19 essentially save the air. Because if anyone was here in
20 the 1970s you could not see the San Gabriel Mountains from
21 downtown Los Angeles and you couldn't see Downtown Los
22 Angeles from the Hollywood hills. And it's not perfect,
23 but it's a lot better. And the air control devices that
24 our South Coast Air Quality Management District pioneered
25 have become accepted throughout the world, really.

1 When it came to climate change, California did
2 not throw up its hands and say, "Hey, it's a global problem
3 and there's nothing that we can do about it because it's
4 really China's problem or India's problem or somebody
5 else's problem. We decided to do it and become a role
6 model.

7 Now the rest of the country has not necessarily
8 accepted all of our policies, but some of the good ones
9 that we've taken on, which we're proceeding and which are
10 taking roots, are electrification of transportation, right?
11 There are more electric vehicles in California than in the
12 rest of the United States combined and that's just going to
13 continue and pull along the industry with it.

14 It is amazing to me. I drive a Honda Civic
15 Hybrid, so does my wife. And the ten years since we bought
16 our vehicles, now there are 20 different models from
17 different manufacturers that do better than our car and so
18 our next car, hopefully, will be an all electric vehicle,
19 all right -- to push it.

20 Also, one area that we might consider on the
21 electric side, we have a performance standard. Essentially
22 for any power that's purchased from outside of California's
23 border it has an emissions limit. And so that, under long-
24 term contracts that essentially does away with coal in the
25 mix of our generation. I'm not saying we're going to do

1 that for natural gas, don't freak out, all right? But
2 there are things that we can consider that will have an
3 impact beyond our borders if we do them right.

4 MR. VERGARA: Great. Thank you.

5 We have an audience question. John, do you have
6 a question?

7 MR. SHEARS: Yeah, John Shears, with the Center
8 for Energy Efficiency and Renewable Technologies. I'm also
9 going to be speaking on the later panel this afternoon, so
10 I don't want to take away too much of what I was going to
11 say. But our shop's been engaged in advocacy on the short-
12 lived climate pollutant strategy probably earlier than
13 most, including posting one of the first symposia here in
14 Sacramento and in California, on the issue involving many
15 of the agencies represented here today.

16 One of the ways that we look at methane is we
17 don't just look it at as a climate issue. Our organization
18 originally started as an air quality organization. And we
19 look at methane as an important air pollutant as well,
20 especially when it comes to ozone, which is another short-
21 lived climate pollutant.

22 And in fact, the World Meteorological
23 Organization in the United Nations Environmental Program,
24 through its integrated assessment on black carbon and
25 tropospheric ozone, a couple of years or three or four

1 years ago basically put forward the message that two-thirds
2 of background ozone is the result of methane. And so we've
3 been advocating that CARB, and all environmental
4 organizations that work on air quality, should be looking
5 at methane not just as a climate issue. For us climate is
6 just another form of air -- the climate issue is just not
7 an issue in terms of air quality and air pollution -- but
8 it should also be looked as an important and critical
9 precursor to background ozone.

10 Given that, and what Arthur was just articulating
11 in terms of the improvement in air quality in the L.A.
12 Basin etcetera, how could the EPA further extend what it's
13 doing to assist California -- recognizing that California
14 still may be a bit reluctant to move forward on the air
15 quality angle on methane -- to help us get the foot print
16 down further than is currently envisioned.

17 Forty to forty-five percent is good, but what
18 we're looking at is we have to get basically a near zero
19 tolerance policy on leakage from the natural gas system for
20 it to be a climate benefit. We need to get it down to a
21 system-wide average leakage rate no greater than 2 to 3
22 percent depending on whether you're using technology
23 warming potential, global warming potential, what have you.

24 So given that EPA also has authority over air
25 quality, is there more that EPA could be doing given that a

1 lot of the regulations are state-level issue, could the EPA
2 be doing more using that angle to help California and the
3 ARB be again the first mover in this space.

4 MS. MARTYNOWICZ: Thanks. Yeah, that's a great
5 question.

6 Sure, I think there's always an opportunity for
7 more, especially for those existing sources. One thing I
8 know nobody ever really wants to hear but is enforcement.
9 And so ensuring enforcement of existing rules, VOCs for
10 example, which of course would be in turn reducing methane
11 if you're fixing leaks at the end of the day.

12 I unfortunately was not able to be here
13 yesterday, but I believe there were some JPL and NASA
14 presentations. So we've been working with the researchers
15 there on helping them determine what sources or facilities
16 to be looking at for monitoring for these pretty large
17 significant sources. So I think that's a start.

18 As we've all heard, our information is only so
19 good as the data that we're collecting. And so we've been
20 working with them to be providing a list of facilities that
21 we know that where there are some potential opportunities
22 for reductions. And then with our upcoming roles, also, at
23 the end of the day, there will be enforcement as well.

24 I know EPA throughout the nation has taken a
25 variety of enforcement actions from various natural gas

1 facilities.

2 MR. SHEARS: So maybe this might be too probing a
3 question. So based on all of the work -- and this past two
4 days has been fantastic I think for anyone else in the
5 world that hasn't been working in this space this is a
6 great deep dive and introduction into all of the issues and
7 what's being done to deal with those issues.

8 Is there thinking going on within the EPA to
9 further extend, tighten the regulations? Again,
10 highlighting the fact that you can also use the ozone
11 precursor angle given that there are these regulations that
12 are basically in flux, in motion right now. So is the EPA
13 willing to consider being more aggressive given that we
14 were having all this very fresh, very revealing research
15 demonstrate to us what's really happening in the system?

16 MS. MARTYNOWICZ: Yeah. I would say definitely
17 so. And I would definitely encourage you, and like I said
18 the others, to provide comments on our Information
19 Collection Request.

20 We're going to be creating two different forms of
21 a survey. So a draft survey that's out collecting those
22 comments, incorporating those comments, and then sending
23 out a second draft survey to the public to providing final
24 comments. And so definitely encouraging folks exactly to
25 do that.

1 And then we're also going to be having a
2 voluntary information collection request for academia, for
3 researchers, for industry of course, as well as regulators
4 on providing information to us -- state information that
5 will in turn help with these draft rules.

6 MR. O'DONNELL: May I ask Trina a follow up
7 question?

8 MS. MARTYNOWICZ: Wait a minute, Art. Who was
9 allowed in (indiscernible) other panel? (Laughter.)

10 MR. O'DONNELL: I'm still a journalist. I'm
11 still acting as a journalist.

12 But we all have to deal with constraints, all
13 right? And as I alluded kind of at the local level we get
14 beat up for not doing enough. At the federal level EPA
15 gets beat up by Congress for doing too much. So in this
16 particular area you've got lawsuits against the Climate
17 Action Plan and many of your other policies.

18 In this particular area what do you see as the
19 political constraints that you might have to try and
20 overcome? Not just Region 9, but EPA as a whole?

21 MS. MARTYNOWICZ: Yeah, that's a loaded question.
22 And come November I should mention, especially it being a
23 Primary Election today who knows right, where we'll be as a
24 nation? So yeah, we do take into consideration that we are
25 here in California, in our bubble for good, for bad.

1 But yeah, there are a lot of constraints
2 throughout the nation. And that's why I think the rules
3 that we finalized a few weeks ago were very challenging,
4 knowing that there's of course progressive states like
5 California who are in the process of drafting rules,
6 compared to those other states that are suing us left and
7 right on pretty much all activities under anything on air
8 quality. So, a lot of opportunity, right?

9 MR. VERGARA: All right, I'm going to switch
10 gears here and read out a question that was posed online.
11 It's pretty much in the weeds, but we'll ask it anyway.

12 This is with regard -- this is a question
13 involving aging pipes and pipelines and what to do about
14 them. So the question is, "It's my understanding that the
15 pipes involved in the Aliso Canyon leak and many of the
16 distribution lines around the state are decades old; some
17 as much as 60 years old. What effect does pipeline age
18 have on likelihood of leaks and do any of the proposed
19 regulatory actions focus on requiring pipe replacement at
20 regular intervals?

21 MR. O'DONNELL: I'll hazard an answer to that
22 recognizing that I'm actually fairly new to the Safety
23 Enforcement Division, only a year into this. But this is
24 something that we deal with all the time. And maybe we can
25 take up this in the next panel as well because we have

1 operational experts.

2 It's not just age, right? You have type of pipe
3 and California is actually blessed in that we don't have a
4 lot of clay pipe or lead pipe still in the system, whereas
5 cities and communities back East still feature that. And
6 those are far more prone to leaks on the distribution
7 level.

8 There is also still some remnant of the vintage
9 of plastic pipe -- we call it Alydyl-A -- that was inserted
10 in the '70s, I believe. But our utilities have been
11 working really hard to try and replace that. There's still
12 some there. But that represents probably the biggest
13 vulnerability in the system, because we didn't know as
14 much. We thought plastic was forever, but its brittle and
15 it cracks and it causes leaks and it needs to get replaced.
16 Again, there are other places in the country where it's far
17 more of a problem for us.

18 Our situation that we've discovered is that no
19 matter how much money we put into the system, the
20 replacement of pipes cannot keep up with the aging. That's
21 just a fact of life. You know? Under the best of
22 circumstances as approved in general rate cases we're still
23 looking at maybe 100 years before we can turn out the
24 entire system and replace it with now, what would be state
25 of the art, but who knows what that would look like in 50

1 years? Would it have its own problems?

2 So you could say that it's hopeless or you could
3 say that we'd better be better at identifying where we need
4 to replace and repair. Detection is one of the ways you do
5 that, understanding the chemistry of the system is another,
6 because one pipe in a dry area is not affected the same as
7 a pipe in a moist, wet area, like the Delta. So you have
8 to focus your efforts in the places where your risks are
9 the greatest.

10 And I'll stop there to keep from getting in
11 trouble.

12 MR. VERGARA: Okay. Thank you.

13 Any other questions from the audience; if not, I
14 have some other questions.

15 All right, I have a couple here. I think he
16 raised his hand first and then McKinley.

17 MR. ZENG: My name is Yousheng Zeng with
18 Providence. I'd like to ask a question about a leak
19 definition. In the regulatory framework, especially for
20 the LDRAR Program, a leak or not a leak is defined by
21 sniffing, and to measure the concentration measured as ppm.
22 That was because of a lack of other ways 20 or 30 years
23 ago. Now, we have methods to quantify. And in the past
24 couple of days there has been a lot of discussion about the
25 quantification in terms of a mass leaking rate.

1 I think we all agree that a mass leak rate is one
2 to the agency or the management who will need -- ppm
3 physically really does not directly correlate to what is
4 the leak rate. And the EPA did that because of, again,
5 historical reasons.

6 So now, we're going to -- or I hope that a
7 regulation is going to eventually migrate toward the actual
8 mass eco-rate (phonetic) based type of management system.

9 In the recent rule of three weeks ago that the
10 oil and gas (indiscernible) there's a number there that
11 shows a 60 grams per hour leak rate. Basically, that's the
12 kind of a --

13 So my question is can we consider that as the
14 EPA's current view as basically if it's smaller than 60
15 grams per hour it's not -- well basically is that kind of a
16 new trend to have some sort of cut off of about 60 grams
17 per hour, is that one?

18 Another related question is that we heard a lot
19 about super emitter? I don't recall if there's some -- I
20 know there's not going to be a clear cut -- and to what
21 level -- but kind of an order of magnitude if anybody on
22 the panel can say? Well, we consider first of all at lower
23 level what a mass leak rate will be significant enough for
24 the agency to consider?

25 Next is what is the kind of general range for the

1 definition of a super emitter?

2 I also understand that especially for the lower
3 part of that you can say well, if you have a definition
4 that is let's say 60 grams per hour does that mean
5 everybody that -- all the component that is not detected
6 will have to use that upper limit? To kind of like in the
7 general chemistry use the detection limit for everything
8 that is not detected, which will cause a huge number too.

9 So what is the agency's kind of view on that and
10 just to run that? Thank you.

11 MS. MARTYNOWICZ: Yeah. In regards to this
12 specific EPA rules and the kind of cut-off rate of the -- I
13 honestly can't answer that, but I'm happy to put you in
14 touch with those folks that actually wrote the rule and are
15 going to be able to answer the question. I don't want to
16 give you misinformation, so please come see me afterwards
17 and I'll definitely connect you with those right
18 individuals.

19 MR. VERGARA: Okay. And I think there was a
20 question from McKinley up there.

21 MR. ADDY: Yes, is it on? I'm fine, okay thank
22 you. McKinley Addy with AdTra.

23 This question might inform a possible comment at
24 the end for the CEC's IEPR Workshop. But with the Aliso
25 Canyon leak and concerns about fugitive methane emissions,

1 what is the current thinking, perhaps from a regulatory and
2 policy perspective about the opportunities for
3 transportation of natural gas? I thought that this might
4 be something that Laurie might want to --

5 MS. TEN HOPE: Well, I think the policy -- well
6 I'm sure the Air Board would want to address it as well --
7 but from a policy perspective I think it fits into the
8 question, in the bigger picture, of what's the role of
9 natural gas.

10 The Energy Commission in their research program
11 has looked at natural gas as at least a transition fuel for
12 heavy duty applications that are not likely to electrify in
13 the short run. So we see some applications for natural gas
14 heavy duty and we've provided research for the last few
15 years and anticipate doing that for a while. How long or
16 what the alternatives might be mid and long-term to
17 completely transition away, I think is a question that
18 requires more analysis.

19 I'm not sure if the Air Board wants to speak to
20 the future of natural gas in transportation as well?

21 MR. VERGARA: Yeah. I mean, just very briefly,
22 because the vehicular side of things is not generally in
23 our shop. But I do see my counterpart in the Mobile Source
24 Control Division here who fortunately just walked in, so we
25 can ask him to chime in.

1 You know the general policy thrust for natural
2 gas in our vehicular direction is that in the heavy-duty
3 side we would be looking at zero emission technologies
4 everywhere that's possible. And then where it's not
5 feasible then we would be looking at near zero
6 technologies, which would encompass things like ultra low
7 NOx diesel engines being powered by renewable natural gas
8 or renewable diesel, for example, so things like that would
9 be kind of our general policy direction.

10 Maybe Jack, if you want to chime in and kind of
11 elaborate or correct me if I'm wrong?

12 MR. KITOWSKI: No. That's great, Floyd.

13 Jack Kitowski, Chief of the Mobile Source Control
14 Division. Yeah I think Floyd is exactly right. There are
15 several strategies we're going to need (indiscernible)
16 excited about. Cummins has a very low .02 gram NOx engine,
17 usage of that, engines like that along with renewable
18 natural gas, are going to be a key part moving forward.
19 There are some (indiscernible)

20 (Audio cuts out briefly.)

21 MR. KITOWSKI: There are some areas like transit
22 buses, last-mile delivery where we're excited about the
23 probability of going zero emission, but that's challenging
24 across the heavy-duty sector. So we see a combination of
25 technologies being necessary there. But natural gas

1 certainly plays a role, but it plays a role as low NOx
2 engines with renewable natural gas (indiscernible)

3 MS. TEN HOPE: If I could just add on the
4 renewable natural gas picture, I think we've done analysis
5 of different strategies to get to the 2050 goals. The role
6 of biomass can play such an important role in either
7 generation as a renewable source for load following, for
8 renewable natural gas in transportation applications, and
9 also for de-carbonizing the natural gas system.

10 And so but it's a limited resource, so figuring
11 out the highest and best value for the renewable natural
12 gas is really important. So we kind of have our fingers in
13 all of those to enable all of them, but we don't have the
14 fuel source to really support them all at a large scale.

15 MR. SANDER: Well thank you for that, Steve
16 Sander, CalRecycle.

17 On that specific issue of biomass and renewable
18 natural gas production and in the context of EPA as well,
19 how does that jibe with the goal of reducing food waste
20 input into landfill?

21 MR. VERGARA: Well, I'm not a panelist, but I can
22 answer that question.

23 We took to our Board, the Air Resources Board, a
24 short-lived climate pollutant strategy for their
25 consideration last month. And we'll be taking into account

1 any public comments we receive and then revising our draft
2 strategy accordingly before we take that back to our Board.
3 A big part of that strategy is what to do with waste. I
4 mean that's definitely a major policy direction for us at
5 the Board, working in conjunction with you folks at
6 CalRecycle and other sister agencies.

7 A key part of that strategy is organics
8 diversion. Trying to get -- virtually eliminate the
9 organics that are going to the landfill. And then those
10 organic wastes that are not going to a landfill, but can be
11 put to the highest and best uses, we would be looking at
12 enhancing the penetration of digesters for producing
13 biomethane that could be made into useful energy and fuels,
14 looking at enhancing our composting system, looking at
15 alternatives to a chemical conversion, so a thermal
16 conversion to biomass to produce useful fuels as well.

17 So the short-lived climate pollutant and other
18 efforts that we're undertaking basically embody a holistic
19 look at our entire cradle-to-grave, including the waste
20 side of things, to make those into useful products, so that
21 we are displacing petroleum fuel as much as possible.

22 MS. MARTYNOWICZ: Yeah. And I should also
23 mention we have a few tools, that I think we could do
24 better probably at marketing and communicating.

25 We have our CoEAT tool, it's a pretty basic

1 economic feasibility of food waste and the co-digestion of
2 food waste at waste water treatment plants for the purpose
3 of biogas production, using publicly available data and
4 calculating the different economic, environmental, and
5 operational outputs of what type of -- how much biogas
6 would be produced at the co-digestion facilities, for
7 example.

8 We also have a biogas mapping tool, so it's
9 looking at major food waste companies, organizations,
10 entities. So everything from like grocery stores, I think
11 dairies are included as well.

12 And we also fund a few different types of kind of
13 more broadly biogas projects or activities. We're
14 providing funds to San Joaquin Valley Air District under
15 their technology advancement program to get biogas projects
16 up and running.

17 We're also looking at ultra low NOx engines.

18 There's also a pipeline injection project that's
19 still kind moving forward in a variety of permitting
20 phases, looking at high solid green waste.

21 And then we have funded through our Diesel
22 Emission Reduction Act grant retiring old diesel trash
23 trucks here in Sacramento at Atlas Disposal, which is a
24 food recovery facility, for refuse trucks that run on
25 renewable natural gas, so just a few activities.

1 We're also doing some research, kind of more
2 broadly on biogas, looking at the different biogas
3 processing technologies. And the costs associated with
4 those technologies and then the air quality benefits, of
5 course, methane being one of those, so yeah.

6 MR. VERGARA: Great.

7 Anymore questions from the audience? We did
8 receive some questions online. I can read those.

9 All right, while you're going over there let me
10 read this question online. It's a little bit in the weeds
11 and may require some follow-up with this person. I think
12 this is best addressed to ARB and possibly to Brady from
13 DOGGR.

14 "How is looking daily for leaks on Aliso Canyon
15 surface equipment going to find a downhole containment
16 failure in a nascent stage; isn't such a daily LDAR on
17 surface equipment a waste of resources?"

18 MS. SCHEEHLE: So I think Brady may have
19 something to add here, because there is multiple components
20 going on.

21 What I was speaking of was the leak detection
22 repair sort of above ground, saw dustings, and DOGGR is
23 looking at the downhole side and regulations on that side.

24 We do feel like when you're dealing with storage
25 facilities where you have a high-pressure situation a lot

1 of natural gas and the potential for a lot of emissions,
2 that looking at daily or continuous monitoring is
3 important.

4 And we'll continue to -- obviously this is an
5 open regulation. We've just put it out there, so if there
6 are comments on that we welcome them. And we will be going
7 to the Board in July, but we think this is an important
8 component to make sure that we find leaks early. And as
9 you heard earlier today those leaks can happen at any time.
10 There's not really -- people haven't been able to pinpoint
11 when that's going to happen. So having regular checks is
12 important.

13 MR. VAN ENGELEN: Right, so I think the key word
14 that Elizabeth said there is component.

15 And the daily leak detection is just one
16 component. There's also a lot of downhole testing that's
17 required. So when you look at it globally, the bigger
18 picture, it should capture everything which dramatically --
19 and a lot of people on this panel have mentioned looking at
20 the bigger picture beyond just your agency -- and not
21 looking at it through a straw hole through your agency.
22 But also looking at the other components as well too, which
23 complement the bigger picture.

24 So while leak detection is only a part of it, and
25 it may seem inconsequential to some, it can add and provide

1 information to the bigger picture. So I'd say there's
2 value there for sure.

3 MR. O'DONNELL: If I might add, there's an
4 assumption that's built into that question, which is that
5 the technology that's used for continuous monitoring is
6 ungodly expensive. And that is not necessarily the case.
7 It may be expensive now, but we're certainly coming down
8 and coming down rather rapidly, because of advances and
9 because of use.

10 So think about it in this way -- aside from being
11 an energy reporter I was also a medical reporter at one
12 time. And you're not going to do an MRI every day if you
13 have a heart condition. But you are going to take your
14 pulse. You are going to take some medicine for the high-
15 blood pressure. You are going to do other things on a
16 regular basis. And those things come down in cost the more
17 they're used, the more people use them, when drugs go to
18 generic, right, as opposed to proprietary.

19 When Picarro becomes generic then it'll be a lot
20 cheaper than it is today. (Laughter.)

21 You've got to start somewhere. And if your goal
22 is to have a continuous sense of the pulse of the system,
23 of the heartbeat of the health of the system, you make that
24 investment, because what's the price tag otherwise? \$650
25 million now for SoCalGas? Deanna got that.

1 Okay. How many devices could that have bought?

2 MR. VERGARA: Yeah. No, that's an excellent
3 point.

4 Did we have a question back there as well? Okay,
5 go ahead.

6 MS. PISTEY-LYHNE: So there was a good point made
7 at the end of the day yesterday in public comment, which I
8 haven't really heard brought up by any of the panelists.

9 Given that this whole conversation is about
10 natural gas and how to mitigate leakage and how to bring
11 down the climate impact of natural gas. And however no one
12 has really talked about the fact that what we're actually
13 trying to get out here is getting away from a fossil fuel
14 economy and moving toward clean energy is to really
15 mitigate climate impacts.

16 Using the latest ITCC's (phonetic) technology
17 warming potentials, natural gas at a 2.8 leakage rate
18 negates any climate benefit over coal. And what we've seen
19 over the last day and a half has been that leakage rates
20 are far exceeding that across entire life cycle.

21 I'm interested in given California's situation
22 with the Aliso Canyon situation and this summer, the
23 concerns that we will run short of natural gas and that we
24 have this emergency kind of regulation, promulgation of the
25 situation, is there any way in which this can trigger some

1 sort of quicker implementation of demand response or
2 renewables plus storage being implemented in order to be
3 able to avoid the concerns this summer? Are those being
4 looked at from a regulatory perspective within the CEC or
5 the CPUC?

6 And kind of how can this situation be used to
7 drive forward getting away from a natural gas economy,
8 which we understand is a problem in many ways from health
9 and climate concerns, and actually moving forward clean
10 energy?

11 MR. O'DONNELL: Well, I'll step up to that one
12 and again challenge some of your assumptions is that
13 methane and GHG gasses is not the only basis of comparison
14 between natural gas and coal. There are a lot of other bad
15 things associated with coal that are not associated with
16 natural gas. And that has gone into the figuring.

17 Everywhere else in the United States natural gas
18 is a clean alternative to oil and coal. California is the
19 only place that I know of where's it's the devil. And I
20 like natural gas. I like cooking with natural gas, all
21 right? I am steadfastly a proponent of reducing the
22 leakage to the extent that we can possibly, so that it is a
23 continued valuable component of our system.

24 Having come more from the electric side than the
25 natural gas side -- let me preface this -- I published a

1 book once called "The Guilty Environmentalist." I am a
2 guilty environmentalist, which means that I cannot always
3 live up to my highest ideals, okay?

4 My highest ideals are totally with Adam
5 Hochschild and Mark Ferron when they say we should
6 electrify 100 percent of the system. My knowledge of the
7 system tells me it's going to be a long time before we can
8 really do that, because the way the electric system runs,
9 it needs spinning turbines. And one of the ways that you
10 spin turbines is to boil water and create steam and it
11 spins the turbines.

12 Now we have some other technologies that are on
13 the edge now of being accepted, which can help provide some
14 of that system support, energy storage. I was hired in
15 fact to help the California Public Utilities Commission get
16 an energy storage procurement target in place. I'm all for
17 that.

18 But you can't have storage everywhere. You can't
19 have 100 percent PV, because of the impacts on the local
20 distribution system or doing away with the local
21 distribution system. You can do it in a step approach.
22 And I firmly believe that it's going to be easy for us to
23 move to a 50 percent renewable system in California. I
24 kind of believe that we can get to a 75 percent renewable
25 system. I'm not sure we can get to a 100 percent renewable

1 system.

2 If you can prove me wrong, great come back in 10
3 years, because 10 years ago utility engineers told you that
4 15 percent was the gap. "As soon as we get 15 percent on
5 any circuit the whole thing is going to go to hell." Well,
6 we have circuits that have 65 percent of photovoltaics on
7 them. And they have some problems. And they have to get
8 bolstered with storage and with new capacitors and with new
9 electronic devices that help smooth out the system.

10 When you blow that up to a system which is 50,000
11 megawatts of peak load during the summer, with transmission
12 lines throughout the state that need voltage support in
13 order to keep from collapsing, I have a hard time getting
14 past 75 percent.

15 MS. TEN HOPE: Well, I think the Governor's
16 Executive Order in response to Aliso Canyon did direct the
17 agencies to do whatever they could to deploy energy
18 efficiency demand response and other strategies in the
19 short run.

20 And maybe Arthur can speak to the energy
21 efficiency. I don't really know what the utilities have
22 been directed to do specifically in their deployment of
23 energy efficiency.

24 On a sort of a more -- I don't want to say
25 symbolic -- but because in our research program where we

1 can we have a lot of active demonstration projects. And
2 where we can we're deploying those specifically in Aliso
3 Canyon. We've just funded several demand response
4 projects. And if they have a -- some of them are really
5 tied to particular sites and locations in the state. But
6 we've asked our managers to work with the researchers to
7 deploy as many of the demonstration projects as possible in
8 the area. And we're also targeting our food waste bio
9 solicitation to that area.

10 So those are really just short term. But I think
11 Arthur and others have spoken to the policies that
12 California has in place to move us from natural gas with
13 the 50 percent renewables, 50 percent improvement in energy
14 efficiency. And then all the underpinnings of efficiency
15 and research programs to get us there with ZNE standards,
16 ZNE pilot projects, and then overcoming what some of those
17 barriers are. So they're, I'm sure, not news to anybody,
18 but technical barriers to get to those goals.

19 And then also testing different strategies where
20 -- you know, that make them more acceptable and increase
21 the market penetration of technologies. So we're working
22 in large deployments with ZNE with builders and doing
23 behavioral sort of research on what strategies are more
24 palatable and are going to really increase the uptake.

25 And gas cooking is one of the things that is a

1 real challenge, because if you could completely electrify,
2 you save all your distribution infrastructure on new
3 construction. But people don't want to switch. And that's
4 such a challenge, because it seems like such a simple
5 thing. But it really sort puts a big challenge in the cost
6 effectiveness of what could otherwise be a full electrified
7 subdivision or power park.

8 MR. O'DONNELL: Yeah. I'm going to try to move
9 fast, because we have another panel and I don't want to
10 take away from it.

11 But I have a long memory and back in 1981-'82
12 there was a rate-payer revolt in California that didn't
13 have anything to do with restructuring. It was because so
14 many customers were on all-electric service. And there was
15 a price spike in electricity. And it was not mediated by
16 natural gas, because we didn't really have natural gas in
17 the system. There were whole swaths of California that
18 were not served by natural gas. So you always run that
19 risk, right?

20 Right now we're in one of those blessed periods
21 where natural gas at the well head is a buck, all right?
22 And that actually kind of inhibits a lot of alternatives,
23 because people in their mind say, "Why should I spend on
24 research when it's so cheap?" But you have to get past
25 that.

1 Laurie alluded to quite a number of things that
2 are in the works. No one can ever accuse California of not
3 having enough energy policy or not trying enough things.
4 And the Energy Commission is ripe with menus of things that
5 we're doing. They have to get accelerated under this
6 circumstance.

7 If you look at the last two months of Commission
8 meetings at the Public Utilities Commission, a whole series
9 of decisions have been put in, in order to address the
10 specific question that you asked, which is, "What can we do
11 in the short term?" "How do we prevent this possible
12 problem?" And energy efficiency, demand response, have all
13 been ratcheted up.

14 Just the last meeting, we put out a resolution
15 for Southern California Edison to expedite its acquisition
16 of storage in the local area that would be affected by
17 this. There are some constraints. We want those storage
18 units to be in, and in operation by December 31st of this
19 year actually to solve the winter problem, because natural
20 gas is really a winter peaking resource, generally. So
21 we're trying to deal with the short term in terms of
22 consumption and reducing demand in the longer term, in
23 terms of diversifying the resources and moving that faster.

24 And yet we have interconnection problems in which
25 it can take two years for some new resource at the small

1 scale, local level using Rule 21 to actually get
2 interconnected and up and running despite all of our
3 efforts behind it.

4 So you can try and push things faster, but you
5 can only push the river so much.

6 MR. VERGARA: Great.

7 And we are out of time. I really enjoyed the
8 vigorous and full discussion from all the members of the
9 panels or the panelists. I think you all agree that
10 there's a lot going on. The landscape, both regulatory and
11 otherwise, currently and then moving forward there's a lot
12 going on at both the state and federal level.

13 So I do appreciate the panelists' time. Thank
14 you very much for all your insights. And if you can all
15 join me in thanking them, please?

16 (Applause.)

17 All right, then we'll switch over to our next
18 panel.

19 MS. KOZAWA: There's a break.

20 MR. VERGARA: Oh, okay. When is --

21 MS. KOZAWA: Ten minutes.

22 MR. VERGAR: All right, ten minutes, please.

23 Reconvene.

24 (Off the record at 2:03 p.m.)

25 (On the record at 2:16 p.m.)

1 MR. O'DONNELL: Not only can you please take
2 seats, can you take seats up front, all right? Can you
3 move down? We have a lot of open space here. It's always
4 a hazard of two-day conferences, even one-day conferences,
5 that the very last panel of the day is marked by attrition.
6 I used to say at conferences, "Here we are, the few, the
7 proud, the ones who couldn't get early flights out."

8 (Laughter.) That's not necessarily the case in Sacramento,
9 but there is an Irish saying, "We may be small, but we are
10 mighty."

11 All right, and I'm actually pleased to see so
12 many of you sticking around for the rest of the afternoon.

13 MS. KOZAWA: Sorry to steal your thunder, Arthur,
14 but I just wanted to make one announcement. If you do have
15 public comment for the CEC IEPR Workshop, please go ahead
16 and fill out a blue card, which is in the back on the back
17 two tables and hand it to one of the CEC liaisons that I'm
18 kind of waving my hand around to, back there.

19 Thank you, very much.

20 MR. O'DONNELL: We talked about the evolution of
21 technologies, the evolution of regulation, the sense of
22 things changing. And one of the things that's going to
23 change, mark my words, in the next three years is the heavy
24 use of the word "stakeholder." Many people find it to be
25 not adequate to explain the variety of positions and kind

1 of perspectives that come into play in any forum.

2 We used to use "special interests," right? And
3 then it turned out that everyone was a special interest and
4 so stakeholders was used to kind of signify that people did
5 have a stake in what was going on and broaden the sense of
6 who has an actual stake.

7 And so over the course of the last 50 years
8 really decisions that previously and been made between
9 regulators and utilities now involve a whole host of
10 stakeholders that get active in proceedings. I was floored
11 by EPA's comment that they got 900,000 comments on a
12 rulemaking. Every single one of those is a stakeholder,
13 but we'll have to come up with a better word.

14 This is the stakeholder's panel then, I'm Arthur
15 O'Donnell. I'm a Supervisor in the Safety Enforcement
16 Division at the California Public Utilities Commission.

17 Joining me today will be Christine Cowsert who is
18 Senior Director of Asset Knowledge and Integrity
19 Management, a big title for a very small business card, at
20 Pacific Gas and Electric. Deanna Haines, who is Director
21 of Gas Engineering -- Gas Engineering and System Integrity
22 -- a much more traditional type of title, Deanna. Briana
23 Mordick, who is Senior Scientist at NRDC and John Shears
24 who has no title, because the Center for Energy Efficiency
25 and Renewable Technologies is a very horizontal

1 organization, in which everyone has an important role
2 including John.

3 So as we have in the previous panels I'm going to
4 just kind of roll down the line and give everybody a couple
5 of minutes to state their positions and then we'll open it
6 up to questions. I have a couple and will really look
7 forward to some from the audience.

8 MS. COWSERT: Okay. So I'm Christine Cowsert
9 from PG&E. PG&E is really focused on delivering safe,
10 reliable, affordable and clean energy to our customers.
11 And the clean part is what we're here to talk about today,
12 a key piece of that being greenhouse gas emissions and
13 methane emissions, reducing those for California's
14 environment.

15 Since 1998 we've reduced our overall emissions as
16 a company by 70 percent and since 2010 we've been really
17 focused on reducing the number of leaks in our system, our
18 Grade 2 and 2 Plus leaks being reduced by over 99 percent
19 in that time period.

20 PG&E was also the first investor owned utility to
21 be in support of AB 32 and we're currently working with the
22 State Legislature, ARB, CEC and the CPUC as well as other
23 stakeholders to make sure that the implementation of AB 32
24 is a success.

25 So first I want to talk a little bit about some

1 of the things that we're doing from a research and
2 development and system upgrade standpoint that are helping
3 us reduce methane emissions from our natural gas system.

4 So from an R&D perspective we're focused on
5 detecting leaks and repairing leaks in a much more
6 effective way, both by land and by air. With the air
7 portion of our R&D work we've using LIDAR technology to
8 detect leaks as well as working with NASA's JPL, who I
9 think are out in the lobby here, to implement their
10 technology, which is a very sensitive methane detection
11 technology via drones. So we've been doing that research
12 with UC Merced over the course of the last several years.

13 From a land standpoint we've had a longstanding
14 partnership with Picarro who I know, as I was walking in
15 today, is parked outside. And we've been doing a
16 significant amount of work with them to use their
17 technology to survey our system. So this year we're
18 planning on surveying about 23,000 miles of our natural gas
19 system using that technology, which is 1,000 times more
20 sensitive than the traditional leak survey technology on
21 the market today.

22 We've also been partnering with Picarro to work
23 on our end-to-end leak management systems, so not just the
24 detection of leaks, but also what we do with the data
25 associated with that, how we start to use that to build

1 analytics to understand what's driving our leaks on our
2 system, understand what the potential methane emissions are
3 associated with those leaks.

4 So a significant amount of effort has gone into
5 using that technology not just to help us manage leaks from
6 a safety standpoint, but also manage them from a methane
7 emissions standpoint.

8 In addition, we're partnering with Stanford to
9 look at how we can leverage Picarro to look specifically
10 for super-emitting leaks. So we've been using it for our
11 traditional compliance survey on our distribution system
12 and transmission systems. But this would actually take it
13 to a different level beyond that compliance view, looking
14 specifically for larger leaks to identify them and mitigate
15 them more quickly.

16 So in addition to the leak survey work we've been
17 doing we've made a significant amount of investment in our
18 system over the course of the last several years in
19 replacing pipe. And while this work is heavily driven by
20 safety considerations, there's actually a fairly
21 significant methane emissions benefit from that as well.
22 So last year on our distribution system we replaced over
23 100 miles of pipe, of our more leak-prone pipe, vintage
24 plastic and steel as well as cast iron. We've eliminated
25 all cast iron pipe from our distribution system at this

1 point.

2 In addition, we've got a program that's focused on
3 replacement of service lines that have a history of
4 leakage. And while historically those leaks would have
5 been repaired we've elected to replace them when we have a
6 leak under the assumption that once it leaks once it's
7 likely to leak again. If we repair it or if we replace it
8 at the time that we detect a leak we're unlikely to see
9 that future leak come to fruition, so again an opportunity
10 for us to reduce methane emissions from our system.

11 And while that work is really triggered by safety
12 considerations we recognize it's kind of a two-for. Some
13 of the other work we're looking at for methane emissions is
14 going to be specific to reducing emissions. That's going
15 to be the focus of the effort and in looking at that we'll
16 want to work with all of the stakeholders involved to help
17 us figure out how to do that in a cost-effective and
18 economic fashion so that we aren't trading off emissions
19 for safety work, as safety is our highest priority as a
20 utility.

21 So beyond the actual physical work we're doing on
22 our system and the research and development work we've been
23 performing, we also have quite a presence around policy.
24 And have been committed to making sure that our methane
25 emissions, our gas emissions are made transparent to the

1 public. So we participated the California Climate Action
2 Registry as well as we voluntarily report our emissions to
3 the Climate Registry, which is a nonprofit organization,
4 but sets reporting standards in North America.

5 And lastly, we have several strategic alliances
6 that we participate in. One that stands out most is our
7 participation in the EPA's Methane Challenge. We just
8 began that earlier this year and that's a voluntary program
9 to help reduce emissions from our natural gas system. And
10 it's a flexible approach, so it lets us target the sources
11 of emissions that we believe will have the biggest bang for
12 the buck in improving our performance.

13 So that's the summary of what we're up to and we
14 feel like we've made significant progress over the course
15 of the last several years in the emissions from our gas
16 system. But through investments in new technologies as
17 well as investing in our assets themselves, we foresee the
18 ability to continue to improve that and to partner with the
19 stakeholders here and outside of this room to help improve
20 further.

21 MS. HAINES: Hi, thanks California Energy
22 Commission, CARB and CPUC. I think this has been a really
23 interesting two days and I guess you save the best for
24 last, hug? (Laughter.)

25 Yeah, SoCalGas and San Diego Gas & Electric are

1 essentially the bottom half of the state. We serve over 20
2 million customers. We've been around for 150 years and
3 it's just unbelievable. I was talking to Briana, I was
4 like, "I can't believe we've been around 150 years." We're
5 part of the community or we have strong unions and we
6 employ over 8,000 folks. And it's -- you know, really
7 proud to work for both these companies.

8 Yeah, one of the things that I want to talk about
9 is the politics and the politicizing of science in a sense.
10 We're at a very interesting time right now. It's very
11 political right now. How many have voted today in the
12 Primary? Raise your hand. It's the political atmosphere
13 right now is just unbelievable. The inflammatory rhetoric
14 around things have reached a new high. And it's really
15 more important than ever now that we allow science to drive
16 policy and data and facts.

17 And I think these last two days, and yesterday
18 especially I heard was just -- I wasn't able to go to the
19 meetings, but I heard it really had a good research
20 science-based flavor to it. So that needs to really drive
21 good policy. We have to stay focused on the facts, focused
22 on policy, that is not based on emojis.

23 And we support all efforts to understand the
24 nature of this issues. And SoCalGas and San Diego Gas, we
25 have a research fund that the CPUC has allowed us to have,

1 that we spend millions of dollars on research to help with
2 energy conservation programs and getting equipment, lower
3 emitting and things like that. The conservation and energy
4 conservation is our number one defense in this whole issue.
5 And it's a really important defense. And it's really
6 helped our companies not only grow the system without
7 increasing emissions, I mean we've been able to grow the
8 system dramatically without increasing emissions. People
9 make the assumption sometimes that if you add more pipe you
10 add emissions and that's just not true. That's not factual
11 at all.

12 And we've been able to actually reduce emissions
13 and grow the system and serve customers. And a lot of that
14 has to do with being very good at implementing energy
15 efficiency programs and developing research around lower
16 emitting equipment. So that's, I think, really good news.
17 And the more that we can do that, the better off I think we
18 are to invest in our systems.

19 To support climate adaptation and manage this
20 risk we must look at a portfolio of options. I'm a hedge
21 person. I have a sail boat, because I can't imagine going
22 out on the ocean with an engine and it dies on me and I'm
23 stuck in a shipping lane. I always like a hedge and any
24 energy system, we now know how interconnected our energy
25 systems are. It's really critical that we have a portfolio

1 of options to tackle these issues.

2 We need resilient energy, a restructure, we need
3 affordable energy, a third of our customers are on CARE
4 programs. It's really unfortunate, but it's a huge issue
5 and I think Art talked about if you've been around long
6 enough energy rates and the cost of a monthly bill for a
7 household is so critical to people. And if a third of our
8 customers can't afford the energy, I mean it creates so
9 much stress and to me this is a health issue.

10 You know, financial stress is a health issue. My
11 parents fought over financial stuff all the time. I mean,
12 this is a huge stress issue for people and families, so
13 affordable energy is really critical. With these limited
14 constraints we need to pick the right solutions that are
15 effective and affordable and don't increase rates
16 dramatically.

17 You know, we have some recent science that has
18 come up -- and I haven't heard it mentioned, but first of
19 all yesterday I understand the Dr. Lam study was mentioned,
20 where we worked with the Environmental Defense Fund and
21 about a dozen other utilities across the nation to kind of
22 update the emissions factors in the distribution sector, in
23 our sector only. And what they found is that the emissions
24 have gone down dramatically anywhere from 36 to 70 percent
25 in our sector. And now this fact is reflected in the new

1 EPA inventory.

2 For the distribution sector emissions have gone
3 down and they will continue to go down. And it's really an
4 artifact of we've been modernizing. Christine talked about
5 we've replaced pipe, none of us in California have cast
6 iron pipe. All of us eliminated that. The gas company,
7 SoCalGas Company eliminated it 20 years ago; we eliminated
8 cast iron from our system.

9 Our San Diego system has only protected steel
10 pipe, has only plastic pipe, it is a super tight system. I
11 call it the super system, and it's really a model for the
12 rest of the systems.

13 So we've done a lot and we also joined the EPA's
14 Natural Gas STAR Program. We were a founding member of
15 that program back in the early '90s where that was about
16 voluntarily reducing methane emissions. That was before
17 any mandatory greenhouse gas reporting on both the federal
18 level and the state level. We recognized over 20 years ago
19 that this is an issue, that we need to do stuff. And we
20 need to be diligent about this. And so we've been going
21 after best practices for our system for over 20 years
22 following the Natural Gas STAR Program.

23 I actually ended up in Russia, helping Russians
24 with this issue, because they lose about 10 percent -- at
25 that time they lost about 10 percent of their gas. And it

1 was unbelievable how much they lost. And we're sharing
2 best practices with them.

3 So we've been at this for a long time and
4 cumulatively in the last 20 years we've saved over 2.5
5 billion cubic feet as a result of our efforts. And we're
6 not stopping. We joined the Methane Challenge Program
7 recently, it's another refresh on the Natural Gas STAR
8 Program. We are going for it again and we think this is --
9 we need to continue going for it. So this is a really
10 important issue. We've been doing it over 20 and we will
11 continue to do as much as we can that we think is cost
12 effective and feasible.

13 How many of you heard about this New Zealand
14 scientist that recently did a study in the Arctic? That he
15 took ice core samples and they found that the carbon, the
16 methane in those ice core samples are biogenic in origin.
17 Anybody heard about that? This is just a couple of months
18 ago.

19 (No audible response.)

20 There's nobody that heard of it? I was surprised
21 that it hasn't been talked about. You know, this is like a
22 huge finding that they took ice core samples in the Arctic.
23 And they found that most of that methane is biogenic in
24 origin. And they think it's coming from increased rice
25 cultivation and livestock, food to feed people. So the

1 increased amount of people on the planet, we're trying to
2 feed them and it's increased our biogenic methane emissions
3 dramatically which ties into, I think, nicely with some of
4 the solutions that we're thinking about around this issue.

5 Now I'm glad to hear that EPA has really backed
6 renewable natural gas. You know, going after those
7 biogenic emissions is I think going to be a critical piece
8 to solving this puzzle for us. So we're very, very pro
9 biogas and very pro renewable natural gas. We see the
10 benefits to disadvantaged communities, to health impacts,
11 things like that.

12 I mean, using renewable natural gas to replace
13 diesel is a huge issue. People that are living by the
14 freeways -- I don't know if anybody has been in L.A. and
15 going down the 710 freeway -- I live in Long Beach and it
16 is horrible. And the people that have to live by these
17 freeways and suck in this black carbon, these diesel
18 emissions, it's just ridiculous.

19 We have technology. You know, Cummins Westport
20 was talked about earlier today, we have technology to take
21 care of this today. People don't have to be suffering
22 anymore, so renewable natural gas is a huge win-win for us
23 and using our systems that are everywhere.

24 One thing that is really unique that I don't
25 think other people have talked about either is that

1 utilities, we have to serve everybody. You know, oil
2 companies, when you go to your Arco or whatever, they don't
3 have to serve everybody. We have to serve everybody. We
4 have to serve people who can't afford energy. We have to
5 serve everybody. That's why we're a utility. We have to
6 serve everybody.

7 And when you think about it if you got your
8 transportation fuel from a utility, whether it was
9 electricity or natural gas you have a lot of people that
10 are looking at our costs. You know, we go through these
11 general aid cases, you have people intervening and looking
12 at our costs, and they're questioning. I don't have that
13 capability and transparency when I go to fill up my tank
14 with gasoline. I have no say in how much that gasoline
15 costs, but if you fuel with electricity or you fuel with
16 natural gas you will have a say in how much that product
17 costs you. Just like you have a say in your monthly bills.

18 So anyway I'm going to leave it at that, but this
19 is a huge opportunity for us. Recent science is saying
20 that a lot of this new methane is biogenic in origin. It
21 doesn't mean that we have to stop doing what we should be
22 doing on the oil and gas side, we still have to go for
23 those emissions, but it means that there's a real
24 opportunity here to make a difference and to go after a
25 huge problem and create a win-win for the climate and for

1 us.

2 MR. O'DONNELL: Thank you, Deanna.

3 Briana?

4 MS. MORDICK: Thanks for the invitation to be
5 here today, Briana Mordick. The Natural Resources Defense
6 Council is a national nonprofit environmental advocacy
7 organization. For those who aren't familiar we were
8 founded in 1970 and we've had a presence in California for
9 nearly all that time.

10 Stopping global warming is one NRDC's top
11 priorities. We come at that from a lot of different
12 angles, but reducing methane emissions is a big part of
13 that work and in particular reducing methane emissions from
14 the oil and gas industry.

15 About four years ago we put out a report called
16 "Leaking Profits," which highlighted this issue and
17 identified ten key technologies to reducing methane
18 emissions from the oil and gas sector.

19 We followed up on that a couple of years after
20 with a report that we, with our partners Clean Air
21 Taskforce and the Sierra Club, called "Waste Not, Want
22 Not," which also again highlighted the scale of the
23 problem, the fact that more recent studies were showing
24 that emissions are potentially significantly higher than
25 what EPA's official estimates show. And again,

1 highlighting these readily available cost effective
2 technologies that could be used to reduce emissions today
3 regardless of what the actual amount of was.

4 In California we've also been heavily involved in
5 global warming issues, AB 32, and now with the ARB's recent
6 rulemaking on reducing methane emissions from the oil and
7 gas industry.

8 We've put out a report about a year and a half
9 ago looking at who's actually at risk from air pollution,
10 from the oil and gas industry in California. We found that
11 more than 5 million Californians live within a mile of one
12 or more oil and gas wells. Of those, about 2 million are
13 living in communities or places that have already been
14 identified by California EPA as areas that are the most
15 heavily burdened by environmental pollution. And of those,
16 nearly 2 million, more than 90 percent are people of color.

17 So reducing pollution from the oil and gas
18 industry is not only a major climate change issue, it's
19 also a significant public health issue and a major
20 environmental justice issue. So there are a lot of
21 compelling reasons to act on this problem swiftly and
22 rigorously.

23 MR. O'DONNELL: Thank you.

24 John?

25 MR. SHEARS: Good afternoon, John Shears with the

1 Center-- the non-hierarchal Center for Energy Efficiency
2 and Renewable Technologies.

3 MR. O'DONNELL: You have to add a couple more of
4 more "e"s. So er-er-er-t. (phonetic)

5 MR. SHEARS: As you can tell we have a long-
6 standing relationship with the PUC.

7 So we're an organization that's actually a
8 coalition of some of the world's leading clean tech
9 companies and leading NGOs. NRDC as one example, is a
10 member of our organization. We were founded back in 1990
11 and 1991 as the Coalition for Energy Efficiency and
12 Renewable Technologies and were founded around the notion
13 that renewable energy could help clean up air quality.

14 So as I mentioned earlier we look at climate
15 pollution as just another form of air pollution. It's just
16 an extension as upheld by the Supreme Court of California
17 as authority to regulate climate pollution as air
18 pollution.

19 I've already mentioned that we view methane as
20 being important, not just as a short-lived climate
21 pollutant, but also as an important contributor to
22 background ozone levels on a global level. There's tons of
23 research in the academic and technical literature that are
24 working on the relationship between methane and other
25 precursors and their role in ozone.

1 So we're here today to talk about the natural gas
2 system. In giving these types of talks I would note that
3 it's been long known that actually since basically the
4 industrial revolution that a growing proportion of methane
5 emissions on the planet are indeed biogenic. So this
6 research that was referred to is just sort of the latest
7 reaffirming what's generally known in the research
8 community around the relative makeup of -- proportional
9 makeup of where methane's coming from in terms of biogenic
10 versus thermogenic. But we're focused on thermogenic for
11 this symposium.

12 In what I would like to stress is the fact again
13 that ten percent of the system's natural gas is indigenous.
14 Ninety percent is national, which essentially makes the
15 California system the national system. So we, in order to
16 ensure that we're gaining true climate benefits from the
17 use of natural gas, we have to make sure that we have a
18 good handle with the help of the USEPA and other federal
19 agencies -- that we have a really good handle on what's
20 going on with the national pipeline system. And the
21 infrastructure that feeds into that system. Otherwise
22 we're not gaining any real climate benefits.

23 So as a lot of the research headed up through the
24 efforts of the Environmental Defense Fund have shown and
25 was mentioned in the previous -- one of the questioners on

1 the previous panel and by myself -- if we're out of whack
2 by 2 to 3 percent in terms of the overall average leakage
3 rate for this system, that negates the climate benefit of
4 natural gas.

5 So we have to really get a handle on this and we
6 basically have to look at every joint, elbow, valve, every
7 connector and every piece of pipe in the system and
8 continuously monitor it in order to be able to track and
9 capture these super-emitters.

10 So Adam Brandt, yesterday, in some of his remarks
11 from the side after his panel, some of the subsequent
12 panels, what I think was trying to get at this issue --
13 which I've also talked about for a couple of years now --
14 which is the magnitude of the problem is huge. And this
15 morning's panel session also was touching upon the fact
16 that we basically were talking about having to collect,
17 monitor, process huge amounts of data if we're properly and
18 vigorously monitoring the system.

19 So the challenge is not an easy challenge
20 although based on what we've seen these past couple of days
21 it looks promising.

22 Now, I want to touch quickly on the concept that
23 natural gas in California policy has been viewed as a
24 bridge fuel, as a clean bridge fuel, to get us from coal
25 intense and fossil intense systems to a clean, more

1 renewably-based system.

2 The original power plant performance standard was
3 established based on a combined-cycle natural gas tailpipe
4 output without looking at upstream emissions. It assumed
5 at the time, the notion at the time -- and this was back
6 2006-2007 -- the notion was that natural gas was again a
7 clean fossil fuel. We now have to wonder about that.
8 So when Arthur is mentioning how clean the natural gas
9 plants are, that's the tailpipe emissions from the turban.
10 That's not dealing with the upstream emissions, which are
11 at issue.

12 And California, yeah we might be the ones most
13 upset about it, but anyone who's trying to move forward on
14 climate policy needs to address, work on and address, the
15 issue around leakage. In terms of getting to the climate
16 goals, 2030, 2050, right now we're focused on 2030 our shop
17 helped convene a consortium of clean tech companies,
18 utilities, DOE, EIA, NREL to produce what's called the Low
19 Carbon 2030 Grid Study.

20 So if you do a Google for lowcarbongrid2030.org
21 you can find an extensive amount of information about the
22 fact that we, by 2030, can reduce the fossil intensity of
23 the California Grid by 50 percent at no additional cost.
24 No silver bullets, using conventional technology, using
25 conventional systems, requires using a lot more flexibility

1 in the system, also requires adjustments in terms of
2 integrating with the wider WEC all the way up through BC,
3 Alberta down to Tijuana, etcetera. Those initial movements
4 in that direction are happening now with PacifiCorp and
5 CAISO.

6 But we can do that without having to build more
7 fossil plants. Ultimately as we get to 2050, which is only
8 34 years away if we're to meet climate goals, we need to
9 get to 80, possibly 90 percent de-carbonization, because
10 everything else that we're doing -- electric vehicles that
11 Arthur also mentioned earlier -- are going to be plugging
12 into that grid. They need to be 80 to 90 percent de-
13 carbonized.

14 Fuel cell vehicles, possibly generated by excess
15 solar as we're seeing with what's called the duck or flock
16 of geese of problem with excess solar in the mild spring
17 and fall days. That's a place where we could also put in
18 an additional beneficial load through the -- it would make
19 economic sense to produce hydrogen for energy storage and
20 as a fuel for a fuel cell vehicle fleet.

21 Our shop's perspective on what the roll of
22 natural gas in 2050 is not that natural gas power plants
23 will be nonexistent, but our view is that by 2050 the Grid
24 will be one dominated by renewables with natural gas on the
25 margins. A flip of the way the Grid has looked in the

1 past.

2 So I just want to put forward that we really need
3 to first get a better handle and ensure that we're gaining
4 real climate benefits, at the same time of the co-benefits
5 that we can get, for air quality in terms of the background
6 ozone problems by really vigilantly going after this
7 problem. And then we can move forward in terms of using
8 that fuel in the context that California policy is a true
9 cleaner fossil fuel that is a bridge fuel to our renewables
10 future. So thanks.

11 MR. O'DONNELL: Thank you very much, John. Thank
12 you all.

13 Let's start with this notion of science, that
14 science should drive policy. But there are few
15 environmental organizations active in the United States
16 that rely more on science than NRDC and CEERT, CEERT is a
17 little bit more on the political science part of it, but
18 definitely science. EDF is another one that is actually
19 based on rational policies based on quantifiable,
20 discernible issues that can be tested and measured in a
21 scientific way.

22 So let's ask the panels today, what you've heard
23 at this conference on the science, what's new to you, what
24 can you then go back and incorporate in your work as a
25 utility for operations or policy and for your advocacy, for

1 your positions? Let's start with John and then come back
2 this way.

3 MR. SHEARS: Well, since I actually follow this
4 research closely -- and I should again mention that the
5 lowcarbongrid2030.org advertisement -- was a peer-reviewed
6 study involving again DOE and EIA. And EIA wanted to be
7 involved, because they essentially wanted to take the
8 modeling work that was a part of that project, because they
9 didn't have the tools to do the national work. So they
10 want to take that work and start using it now for
11 nationally.

12 So we may be political -- NRDC has an advocacy
13 and a lobbying arm -- but we also base our understanding in
14 sound technical understanding of what the issues are. So
15 I've been following this issue, so there's no real surprise
16 for me except maybe the one take-home message is once we
17 get a sense, a true sense of how fat the fat tail is, what
18 portion of that tail that we cut off will be sufficient to
19 get us below that 2 to 3 percent threshold?

20 So there's some promise there in that if we have
21 good confidence that we truly understand what the system
22 looks like, what that fat tail looks like and we can chop
23 off the significant part of it, so again we want to be
24 practical. There's the ideal and then there's what's
25 realistic. That I think is the thing that is most hopeful

1 coming out of this along with the fact that with ARPA-E
2 efforts etcetera that the technology seems to be advancing
3 in the direction of miniaturization and lower expenses,
4 which is all very promising.

5 MR. O'DONNELL: Great, Briana?

6 MS. MORDICK: Yeah. I mean, I think the
7 presentations that we've seen have been fantastic. I saw
8 some really exciting new research. You know, again this is
9 an area that we follow closely as well, but seeing some of
10 the convergence around exactly what are the right questions
11 to be asking, what are the important questions, and where
12 does that kind of lead you in terms of research?

13 Especially some of the new technology that's coming up
14 around actually measuring methane emissions, I think is
15 incredibly important.

16 And I think we're seeing the science pointing to
17 some pretty clear policy solutions again with the fat tail
18 problem. Recognizing that because of the sort of random
19 nature of these problems as everyone kept saying
20 (indiscernible) the importance of more regular monitoring.
21 But then also as many others pointed out as well, for the
22 pieces of the leakage that aren't part of that fat tail we
23 do know that there are again commercially available off the
24 shelf cost-effective technologies that can be employed to
25 address those as well.

1 So I think we're really seeing the science help
2 drive policy that's very clear that these -- again
3 notwithstanding that there's still quite a bit to
4 understand, but that there are clear solutions to this
5 issue.

6 MR. O'DONNELL: Thank you.

7 Deanna?

8 MS. HAINES: You know, I thought today the
9 discussion on big data and data analytics I think is a
10 really good discussion and it's important for us. We're
11 rolling out our advanced meters on the gas system. We have
12 roughly about 6 million meters that we have to roll out and
13 we just surpassed the 5 million meter mark.

14 As part of the data analytics on the advanced
15 meters, we're starting to find leaks behind the meter much
16 sooner than we would have if we had traditional mechanisms.
17 This is really coming out of the high bill investigations
18 that happen traditionally. Usually people would get a bill
19 that's super high and they're like, "Oh my gosh, what
20 happened?" And it would be 30 days after the leak had
21 started or some barbecue was left on, things like that.

22 Well we're now able to see these things happen
23 almost within a few days of when they happened if not
24 sooner. And we're also finding water leaks. People are
25 like, "What do you mean water leaks?" Hot water systems

1 where it could be the exit piping off the hot water or the
2 water heater itself is leaking and it's constantly
3 refreshing with new water and it's having to cycle over and
4 over again. And it's creating all this excessive
5 consumption. We're finding hot water leaks.

6 And it's really fascinating, but I think this is
7 really going to be a breakthrough in terms of our ability
8 to diagnose our system from a holistic perspective to get
9 after the hot spots on our system, the leakiest parts of
10 our system to go after and target replacement for those
11 areas using our new GIS tools, things like that.

12 We're really, big data I think is going to be a
13 game changer for us.

14 MR. O'DONNELL: Okay. And who specifically at
15 this conference raised that, so that we can...

16 MS. HAINES: It was the first panel. It was the
17 company, I forget what it was called, that did the --
18 Viance (phonetic) or something like that?

19 MR. O'DONNELL: Enview?

20 MS. HAINES: Enview.

21 MR. O'DONNELL: Okay, so from this morning's 9:00
22 a.m. to 11:00 a.m.?

23 MS. HAINES: Yeah.

24 MR. O'DONNELL: Right, we're call your attention
25 to that if like me, you weren't able to attend.

1 MS. COWSERT: Yeah, unfortunately I have not been
2 able to attend most of the conference, but from the last
3 panel one of the things that I took away from the comments
4 from the CEC was related to behind the meter and the
5 methane emissions associated with that. And we are
6 deploying a significant amount of technology where we might
7 be able to pick up on more of those things than we've
8 looked at in the past either via our leak detection
9 technology or via our smart meters.

10 And so that was something that I noted as
11 something I'd like to take back and look at more,
12 understanding what we can glean from the data we have about
13 that and whether there's anything that that can help us
14 trigger in terms of work on methane emissions.

15 MR. O'DONNELL: Thank you.

16 Science notwithstanding it's always been my
17 contention that the utility system is ten percent physics
18 and 90 percent accounting, mostly because that's how the
19 money gets allocated.

20 Deanna used the terms cost effective and feasible
21 in her talk and we find these are terms that increasingly
22 get added into legislation directing us what to do. And we
23 are often at a loss as to how one defines that. So I'm
24 going to go down the panel and see if we can reach some
25 consensus on what do we mean by cost effective and feasible

1 in this realm of technologies for the detection, the
2 quantification and the mitigation of methane leaks?

3 John.

4 MR. SHEARS: Are we using 100-year GWP or a 20-
5 year GWP?

6 MR. O'DONNELL: Okay. You can raise questions,
7 let's hash it out here?

8 MR. SHEARS: Just that's another part of what is
9 the appropriate metric in terms of any kind of
10 incentivizing of the system. And the Environmental Defense
11 is proposing -- and this goes back to their original paper
12 in 2011 and 2012 in the proceedings of the National Academy
13 where they recommended this technology warming potential to
14 take into account how emissions work in the real world and
15 how we should really be tracking those emissions.

16 So first I would advocate for a 20 year on a GWP,
17 which then is more closely related to their technology
18 warming potential.

19 Beyond that, you know, again not being an
20 accountant and not really knowing what the relative revenue
21 streams are I don't really have a good answer for you at
22 this point. I know it's more challenging right now with
23 natural gas prices being so low, which makes the solution
24 that more difficult because that means the technology has
25 got to get to that much, much lower price point.

1 But clearly our organization supports that, but
2 we do make the distinction of -- we do recognize near, mid,
3 and long term, so we may not necessarily think that
4 something has to be cost-effective in the near term if it
5 gets us to something that we wouldn't otherwise get to
6 that's cost effective in the mid to long term, so I'll
7 leave it at that for now.

8 MR. O'DONNELL: Briana?

9 MS. MORDICK: Yeah, I mean I'm also not an expert
10 on cost benefit analysis. I think when we're using the
11 term cost effective we're looking at it in terms of --
12 again in the simplest terms this is industry capturing back
13 its own product -- and so the more that they can keep in
14 the system the better it is, obviously, for them.

15 Now, obviously there's been some argument that
16 because of that reason that industry is motivated to do
17 this voluntarily, I think we've seen that that hasn't
18 necessarily always been the case and maybe in different
19 sectors of the industry.

20 You know, EPA just created its new Methane
21 Challenge Program, which is building on the EPA Natural Gas
22 STAR Program. There are 41 companies I think, who were
23 part of the initial sign up for that. Not a single one of
24 those was an E&P company, so no one from the production
25 sector has voluntarily agreed to participate and reduce

1 their emissions. So I think -- you know, well we obviously
2 think that that's why the regulatory roll is so important.

3 But yeah, I think when we're thinking in terms of
4 cost effective these are things that can be implemented at
5 very low cost, because what's being captured back is the
6 product.

7 MR. O'DONNELL: Deanna, and can you bring in the
8 feasible too since you have to live with that? (Laughter.)

9 MS. HAINES: Yeah, we have to actually do it.

10 Yeah, there is a methodology that ICF, a
11 consulting firm, recently put together to come up with a
12 marginal abatement cost curve. And they did see that for
13 our sector, you know we talked about it -- I think it was
14 today we talked about -- there is an 80 times difference in
15 cost effectiveness between different best practices.

16 And for the distribution sector unfortunately
17 it's very expensive to do reductions in the distribution
18 sector.

19 With that said I think the utilities are in a
20 very unique position, because we have to ask for funding to
21 recover our costs. And there's a lot of folks,
22 stakeholders, that have a say in what is reasonable for us
23 to recover. And what we do is essentially say, "Okay, if
24 you want us to do this, this is how much it's going to
25 cost. And here's how much we're going to need to recover

1 that cost." And then they figure out how does that affect
2 rates, how does that affect your energy bill, ultimately.

3 And then sometimes we're able to settle with
4 those intervenors. They say, "Well, we think you need 80
5 percent or we think you need 90 percent, you don't really
6 need all that 100 percent."

7 So to me cost effectiveness in this context is
8 really going to be up to the intervenors and the CPUC in
9 terms of what they think is a reasonable cost for the
10 amount of reductions that we're going to get. I don't
11 think we should be putting a threshold on it. I think that
12 is short-sighted.

13 Right now, as John had said the cost of natural
14 gas is so low, so just saving the two dollars in Mcf is not
15 going to get you much reductions in our sector. It's just
16 not. And so we have to think beyond that, but we have to
17 think about is it going to be affordable for people? Are
18 people going to be able to -- how much is this going to
19 increase people's bills? And is it going to be affordable?

20 And that is a kind of a process that occurs on a
21 regular basis every three years for us, in our general rate
22 cases. And I think the intervenors are going to decide if
23 it is affordable or not, for us.

24 MS. COWSERT: Yeah, I tend to agree. I think
25 that generally we're subject to the rate prayers, right?

1 So we need to make sure that the techniques or the concepts
2 that we're putting in place are considered reasonable in
3 our rate case proceedings.

4 I think there are opportunities for us to get
5 bang for our buck in places where we're getting benefits in
6 other parts of our businesses and methane emissions, right?
7 So some of the things we're doing around replacing leak-
8 prone pipe or doing that kind of work, we do see benefits
9 on the methane emission side. And so those are places
10 where it's obviously very feasible for us to do that work.
11 It's already embedded in our rates, it's therefore very
12 cost effective.

13 I think the piece, if we're starting to focus our
14 attention on work that's specifically for methane emissions
15 we need to come up with a way for there to be a rate-making
16 mechanism for recovery of those costs. That ultimately has
17 to go through the same kind of scrutiny from all
18 stakeholders to make sure that it's achieving the desired
19 objectives as well as doing so within the lines of a
20 reasonable cost.

21 I think from a feasibility standpoint we're
22 exploring options that are maybe not feasible today, but
23 maybe in the future through a significant amount of
24 research and development, partnerships with CEC and others
25 to explore ways for us to at least detect leaks for

1 effectively therefore allowing us to repair more leaks and
2 reduce methane emissions. And so feasibility to me doesn't
3 necessarily mean that it has to be something we can do
4 today, but exploring technologies that we see as being
5 promising over the course of the next several years. Those
6 concepts would also apply.

7 MR. O'DONNELL: Okay. One more term of art that
8 shows up in legislation, and in fact in SB 1371 I alluded
9 to it, is best practices. You'd be surprised that we
10 cannot agree on a definition of best practices. So I'm
11 going to ask folks, I'm going to kind of jump in the middle
12 and ask Deanna to tell us what do you think of when we say
13 best practices? And how does that play out in terms of
14 what you're willing to do?

15 MS. HAINES: You know, I'm an engineer and I
16 think that there's a lot of ways to figure things out and a
17 lot of solutions to a problem.

18 So best practices to me is something that has
19 been tried and true and that there's obviously a
20 commonality amongst the industry of employing that
21 practice, because it seems to be working and it's feasible.
22 And it's implementable and it's a reasonable cost to do.

23 So I'd look to places like EPA's Natural Gas STAR
24 Program that kind of have done this for over 20 years to
25 look for those practices that folks have voluntarily done.

1 And have been proven to be something that does reduce and
2 is workable.

3 And I also look to beyond that, you know, I try
4 to think outside the box with this. Sometimes best
5 practices may not be on our system. We may find that the
6 best way to reduce methane is to interconnect with a
7 renewable natural gas source. That that is really the best
8 bang for the buck for the resources that we have and the
9 limited monies that we have and the constraints, if that is
10 really a better investment for not only the ratepayer, but
11 for the system and the sustainability of the system.

12 So I'd like to think that I would not just follow
13 what's industry best practices, I would look for more
14 creative ways to see where we can reduce methane that can
15 be a win-win for our customers and for the environment.

16 MR. O'DONNELL: Okay. From our environmental
17 stakeholders, anything from you?

18 MS. MORDICK: Yeah, I mean it's definitely not an
19 easily defined term and I think it's partly depending on
20 your frame of reference and your risk tolerance. As an
21 environmental advocate my risk tolerance for a methane leak
22 may be lower than Sempra has a risk tolerance for a leak.

23 And best practices is also something that's just
24 continually evolving. You know, we've talked a lot about
25 the Aliso Canyon incident, that was caused by a well

1 failure. DOGGR hasn't updated their well construction
2 regulations in 30 years, so are they using best practices
3 currently? Probably not, but can we expect regulation to
4 continually keep pace with best practices? We would hope
5 so, but I think the current model we're using of write it
6 once, leave it on the shelf for 20 years and come back to
7 it 20 years later isn't really working, so best practices
8 has to be a process of continuous improvement.

9 MR. SHEARS: Yeah, Briana sort of took the words
10 right out of my mouth. I was going to say that best
11 practices to me is a constantly moving and evolving target
12 based on the best available knowledge and economics of the
13 time. So again, as a public advocate as Briana noted, my
14 tolerance for what should be an allowable leak is going to
15 be different than -- or at least initially different than
16 maybe what industry's tolerance considers to be a tolerable
17 leak.

18 But again, I think it's a matter of putting it in
19 a context of keeping I guess an eye on the prize, and that
20 is we need to. Otherwise humanity is going to have a very
21 miserable existence, we need to figure out collectively
22 across the entire system how we can get to an effective
23 overall 90 percent of reduction in global warming
24 emissions. And it doesn't mean that -- necessarily that
25 means we'll get to 90 percent in every sector. We might

1 get 100 percent in some sectors, but others might fall
2 short.

3 So as that policy around the carbon question
4 evolves and the incentive system built and designed around
5 that changes, that will also affect what can be feasible as
6 a best practice.

7 And then I think we're now entering a phase where
8 we're constantly going to be -- as you mentioned earlier
9 Arthur -- there's never a shortage of energy policy in
10 California. Likewise for the past few decades there's
11 rarely been a shortage of energy research related to
12 developing policy and I think we're going to see California
13 and other jurisdictions picking that model up more and more
14 especially now that my home country of Canada has joined
15 reality again and come back to the fold. Hopefully we'll
16 be able to strengthen the alliances with the provinces and
17 also with the federal government in Ottawa to do a lot
18 more.

19 MR. O'DONNELL: Christine?

20 MS. COWSERT: Yeah, so best practices from my
21 perspective may be even more broadly than the methane
22 emissions base is. You know, I think I look at three
23 places. So I look to my peers right, so industry
24 benchmarking, see what others within the United States,
25 within the world, are doing around a topic. And whether

1 there's anything we can bring back home to apply to our
2 system.

3 We look to industry organizations to help us find
4 some of those where they maybe have information that we
5 don't necessarily have access to, to help guide and provide
6 some insights there.

7 And then I think we also try to look to other
8 industries where there are things that we can steal
9 shamelessly from others to apply to our own industry. So
10 thinking just within the natural gas industry, thinking
11 just within the State of California, we can apply best
12 practices, because we do lead in a lot of places. But
13 there are opportunities to look internationally, there are
14 opportunities to look outside of our industry to find
15 additional concepts as well.

16 MR. O'DONNELL: Okay. I will comment to the
17 audience and anyone listening to look at the CPUC and ARB
18 Staff Proposal. It is a proposal on best practices to
19 apply to methane reductions in the gas system here in
20 California. We recognize that not all of those
21 recommendations will be adopted and we have a spirited set
22 of comments. And so if you can figure out how to use the
23 PUC's website, you can actually find those documents
24 through a docket card or the website portal for the risk
25 assessment section, which I hope is a little bit easier to

1 use.

2 MR. SHEARS: Arthur, you should also mention that
3 the PUC does have staff that can help people who've never
4 navigated --

5 MR. O'DONNELL: Do they? They've never been able
6 to help me. (Laughter.)

7 MR. SHEARS: -- the process before to --

8 MR. O'DONNELL: I mean ARB was trying to get
9 access to our documents, it took them a week right and then
10 they were joined in the proceeding.

11 MR. SHEARS: So anyone who's naïve to being
12 involved with the PUC processes, they do have staff that
13 will help you figure it out.

14 MR. O'DONNELL: Okay. I'll take your word for
15 it, John.

16 Let's see if there's questions from the audience
17 or anything coming in over the transom, please. And do if
18 you have a question how about identifying yourself too,
19 since this is a stakeholders panel we want to know which
20 stake you hold.

21 Thank you, can you hear me?

22 MR. CLAVIN: Thanks, I'm Chris Clavin.

23 MR. O'DONNELL: We're going to start over here on
24 the right and then we'll come over here.

25 MR. CLAVIN: Oh, sorry.

1 MR. FLEISHMAN: Yeah, thank you. My name is
2 Steve Fleishman, I'm a consultant in the energy industry,
3 not a native Californian so the stake I hold is much more
4 remote. But I did have a question about best practices in
5 so far as what's practical and what's economically
6 available. And I wanted to key you on something that I
7 heard on the science side of things yesterday, which not
8 all of you were able to attend, but probably are well aware
9 of.

10 The focus on the fat tail and the benefits of
11 slicing off that tail, to borrow the phrase from earlier,
12 and the practical remedies available to do that at the
13 utility level and perhaps further upstream, my question is
14 basically what do you see out there in the latest EPA rules
15 for the new sources? It seems OGI has been embraced as one
16 way to go about it.

17 MR. O'DONNELL: OGI being?

18 MR. FLEISHMAN: Optical Gas Imagery, didn't hear
19 a lot about in the last day or so, but I'm wondering what
20 your views are on taking this kind of technology which we
21 know is deployed already in the field and applying it to
22 solving, for example, the potentially high value fat tail
23 problem that we've identified as well.

24 I would address that to the entire panel
25 including the regulatory side. Thank you.

1 MR. O'DONNELL: Anybody want to weigh in on that?

2 MR. SHEARS: Well, certainly. I mean any of the
3 optical techniques are powerful at least in making the
4 initial detection and then it's a matter of whether you can
5 use any of those techniques to make the measurement, so
6 that you can actually calculate the fluxes. So we're
7 having a similar kind of to and fro with CAR (phonetic)
8 right now with their oil and gas regulations in how they
9 should inspect and how frequently they should inspect. But
10 I would think any of the optical detection technologies,
11 especially as the market expands for them, so hopefully get
12 the benefits of scale.

13 And in terms of sales and price drops those would
14 be very attractive. As to those solutions in terms of
15 actually figuring out what it is that you've -- how many
16 emissions you've avoided, that's more of I guess a research
17 question than it is an actual field operational question.

18 MR. O'DONNELL: I will weigh in on this. Don't
19 make the mistake of thinking that best practices are always
20 technology. We have taken the stance that the most
21 effective and most cost effective are often process
22 innovations. And you would not think that something like
23 bundling maintenance work, so that you do several different
24 tasks at the same time, would be all that pioneering or
25 groundbreaking. And yet when we match the surveys that we

1 found, that vented omissions from maintenance practices are
2 one of the big ommitters and a heretofore kind of
3 unrecognized problem. I'll say that we've always known
4 it's been there, but there's several things to go into
5 that.

6 If you can get planning such that various
7 maintenance activities are bundled together and you only
8 have one venting situation versus six venting situations,
9 gee you've just saved 80 percent of the emission in that
10 particular case. And then you can work on reducing the
11 venting emission itself by cross compression or other
12 various techniques. So it's not just about technology
13 although we are seeing advances in technology.

14 I'll also say that my own personal perspective on
15 best practices is not tried and true and average and
16 everybody does it. That's conventional wisdom. We have to
17 increase the bar. We have to go beyond that. We have to
18 up the average. We have to find what really are new and
19 evolving techniques, practices and policies that are being
20 used. And then get other people to adopt them, sometimes
21 voluntarily, sometimes not so voluntarily. And that's
22 where policy really comes into play.

23 MR. SHEARS: We should also keep in mind Adam's
24 quick little saying from yesterday, the cheapest detective
25 is not always the cheapest detection. So it depends on

1 what kind of emission sources you're looking at and at what
2 tier or scale you need to be at in order to be able to
3 practically detect those issues.

4 But I agree with you, Arthur.

5 MR. O'DONNELL: Okay. We had a question over
6 here? Yes, right over here.

7 MR. CLAVIN: Yeah. Hi, my name is Chris Clavin,
8 I'm with the Science and Technology Policy Institute.

9 Arthur, I'm actually going to build off on your
10 last comments there about its more than technology. And
11 one of the things I deal with is trying to reconcile
12 between what the R&D community is producing and then also
13 trying to get the user to articulate what their needs are
14 as well too. And at some point get them to match up at
15 some point in the future.

16 A lot of what we heard yesterday was what the
17 research community was producing. These are outstanding
18 scientific questions that they're trying to answer with
19 some very innovative approaches as well, too. And then
20 somewhere in the middle ARPA E states somewhere they would
21 like to achieve. EDF, the methane detector challenge is to
22 put actually labels -- put some numbers down on what
23 capabilities they'd like to achieve with detection.

24 So three broad areas we've been hearing:
25 detection, quantification, and source attribution is what

1 I've been hearing as well, too.

2 So I guess my question to everyone on the panel
3 is what type of capabilities regardless of how they're
4 delivered: technology, outreach, any way possible, what
5 type of capabilities would you like to see from the
6 research community at some point in the future whether its
7 next year, five years from now, ten years from now? What
8 are those types capabilities you would like to see for your
9 purposes?

10 MR. SHEARS: Well, I can start off in terms of
11 the research side, which is -- and, you know, it was
12 discussed, I think it was Chip from JPL and a few of the
13 folks -- is essentially it's the multi -- developing a
14 robust, sustainable multi-tier system, which is what we're
15 going to need I think to really get the handle on what the
16 inventory is to begin with. And then so that's one problem
17 set.

18 And then the next problem set is once you
19 understand that and can work from that point, what can you
20 provide industry, so that you can actually track that
21 overall what industry's doing is effective, once you have
22 that overall robust monitoring system in place. Because
23 industry clearly doesn't need to be bothered necessarily
24 with measuring fluxes and that; they just want to stop the
25 leaks and fix the problems.

1 So I'll just offer that to start.

2 MS. HAINES: Yeah. I think that for us the
3 quantification, the quick quantification of the leak is not
4 as important as just fixing, investing in the system with
5 good material. We really want to spend our efforts and our
6 time fixing leaks and investing in replacing pipes that are
7 leak prone. That gets us the long-term bang for the buck
8 for the system. It makes it tighter.

9 We've seen that dramatic difference between our
10 San Diego system, which I call it the super system, which
11 doesn't have a leak backlog. We don't have any problems
12 with trying to keep up with the leaks we're finding,
13 because its already a tight system. So spending money on
14 investing in the system to make it tighter is really
15 important.

16 If we are going to be monitoring the thing for us
17 is to quickly get that data into an Enterprise system, a
18 GIS system, to see were the trends are, where are the hot
19 spots?

20 For methane, methane's background is between 2 to
21 5 ppm in Southern California at least, so you don't need
22 super sensitive things. You need to be able to see above
23 the background to see the methane -- but for us because we
24 have such natural occurring methane not just from biogenic
25 sources, but from thermogenic sources -- that sometimes

1 just detecting the methane is not enough. We have to go
2 beyond that. We have to see something.

3 What would be great to be able to differentiate
4 natural gas pipeline methane from other methane is to be
5 able to detect the odorant that we all have to put in the
6 natural gas systems. If you could detect the odorant, then
7 we for sure know that's our methane.

8 Otherwise, we're spending a lot of time trying to
9 find a leak that may just be an intermittent source.
10 Somebody turned on their burner, because the equipment is
11 so sensitive. And that is a big waste of time. We'd
12 rather just spend the time planning and repairing that leak
13 or investing in replacing that pipe, because it should be
14 -- it's not the latest (indiscernible) pipe.

15 MR. O'DONNELL: I'm sorry, do I understand that
16 you say that we don't have a very good way of detecting the
17 odorant aside from smell?

18 MS. HAINES: Yeah, besides the smell, which is
19 really the best way -- I mean most leaks -- yeah we have to
20 odorize the gas so that somebody can smell at one-fifth of
21 the lower explosive limit, which is about 10,000 parts per
22 million. But most people can smell it much, much lower
23 than that. They can smell. It's amazing how our olfactory
24 nerves can smell pretty low in the parts per trillion,
25 parts per billion, range. But there's really no technology

1 that can detect at that level.

2 And so it would be great if we could detect the
3 odorant.

4 MR. O'DONNELL: Or we could add something to the
5 odorant that is detectable?

6 MS. HAINES: Like some kind of tracer, you're
7 saying?

8 MR. SHEARS: Yeah, me and the guys that are
9 working on artificial noses to maybe come up with
10 something.

11 MR. O'DONNELL: Somebody mentioned emojis
12 recently. I mean, we -- (Laughter.)

13 MS. COWSERT: Well, you can detect ethane for
14 pipeline gas versus like sewer gas and other things. But I
15 don't know if that gets you close enough to what you're --

16 MS. HAINES: The ethane-methane ratio doesn't
17 really work for us, because we have naturally occurring
18 methane, ethane and propane in Southern California.

19 It's like Saudi Arabia of Southern California,
20 you know, we have the La Brea Tar Pits. Anybody ever been
21 to the La Brea Tar Pits? You know, it's a surface
22 expression of oil and methane and we have ocean seeps that
23 have methane, ethane, and propane.

24 I mean we have producers that produce gas and put
25 it in our system and all of that looks and breathes and

1 feels like a natural gas pipeline. Unfortunately, it's
2 just one of those things in our service territory -- I
3 don't think other people have it in their service
4 territories -- but just detecting methane is not enough
5 for us. We have to go beyond that.

6 MR. O'DONNELL: Harkening back to the medical
7 journalism that I used to do I reported a lot about
8 research. And there are three tiers of research. There's
9 basic research, right, that you would think that after all
10 these centuries we understood how we operate and ourselves
11 as organisms. We don't. And continually new discoveries
12 are made that help us understand that, so there is a
13 component of the research that is needed in the system that
14 is essentially basic research. I think somebody alluded to
15 the ice core samples. That's kind of basic research.
16 What's really the problem and how do we identify the
17 problem?

18 Then there's the research into better detection
19 of health, MRIs, and x-rays and everything and the whole
20 continuum of that. And that's one of the things we're
21 talking about with imaging technologies and sensing.

22 And then there's the applied, what we used to
23 call clinical medicine. And that's what kind of research
24 is necessary for the utilities to do a better job, and
25 would be more efficient in that?

1 I would suggest that all of those things need to
2 be done and concentrated. And that's why we have a grand
3 California Energy Commission with lots of research funding
4 that's available. And they work in partnership with Gas
5 Technology Institute and other things.

6 But it is up to the stakeholders, whether
7 regulators or utilities or environmental groups or others,
8 to help direct the attention towards what should be focused
9 on. It's not enough to expect the research community to
10 come up with these ideas all the time of themselves,
11 because then you'll never get that practical application.
12 They'll always be focused on the basic stuff.

13 So there's got to be a combination there.

14 MR. SHEARS: And don't the EPIC funding.

15 MR. O'DONNELL: Yeah. I'm sorry, the ethnic
16 funding?

17 MR. SHEARS: EPIC.

18 MR. O'DONNELL: Oh EPIC. Yes, EPIC is one of
19 them.

20 There are a couple questions in the back and then
21 over here. So let's start over here and then to Win and
22 then to the front here. Okay.

23 MR. ADDY: Yeah, is this on? Yes, so McKinley
24 Addy with AdTra.

25 And I guess this question goes towards a comment

1 that you just made about what should be focused on, so the
2 need to address the methane leakage is compelling. Some of
3 the information we've heard in this symposium last two days
4 suggests that the trend for methane leakages is sort of
5 (indiscernible) if we use the information that we have
6 presented and I believe the gentleman from LDL. (phonetic)

7 And then when you take into account the new
8 regulations and some of the new technologies for detection
9 and mitigation, one can expect some future additional
10 reductions. So the question is, is there a lower bound
11 methane leakage rate that the stakeholders would like to
12 see?

13 MR. O'DONNELL: Like a threshold rate, somebody
14 was talking about 65 grams or something like that?

15 MR. ADDY: Yeah, I mean --

16 MR. O'DONNELL: I mean, that is a politically
17 fraught situation, because you cannot really equate
18 particular rates of emission with volume of emission unless
19 you know how long it's been leaking. And that requires a
20 whole different set of tools and technologies to measure
21 that.

22 The way that we've done it traditionally has been
23 about safety, right? If it poses a safety hazard, then you
24 fix it right away and then you do that. I'm going to say
25 that it would be a very difficult thing for a regulatory

1 agency like the PUC to do.

2 If EPA is still here, maybe they could talk about
3 it or ARB, but I'm going to kind of say that's going to be
4 a tough one.

5 MR. ADDY: But, you know, forgive me, but
6 generally some sentiments expressed have talked about
7 system-wide leakage rates of maybe low 1 percent or below 2
8 percent?

9 MR. O'DONNELL: Okay. That's an aggregate, all
10 right? And that's a lot easier to figure out than what's
11 the threshold that comes from a distribution pipe or even a
12 larger pipe, because you've got constantly flowing.

13 All right, two different things, I'm going to say
14 apples and oranges there. Anybody else want to --

15 MR. SHEARS: No, I'd agree.

16 I mean, it's a matter -- it's one thing to detect
17 an instantaneous emission as opposed to having an actual
18 picture of what the total emission is, what the flux is and
19 everything.

20 Those are two different challenges with two
21 different potential outcomes depending on what work you're
22 doing around that.

23 MR. O'DONNELL: Kathleen, while the microphone's
24 over there, did you have a question? And then we'll move
25 it to the front here and then back to Win? I thought I saw

1 you raise your hand.

2 MS. KOZAWA: No.

3 MR. O'DONNELL: Okay. All right, then in the
4 front here, center.

5 MR. BRADBURY: Thank you, James Bradbury with the
6 U.S. Department of Energy.

7 I had a question just building on this great
8 discussion, particularly on the issue of best practices. I
9 was interested in thoughts on examples of best practices.
10 At the federal level obviously we're interested in learning
11 from the experience here in California. And any sort of
12 innovative approaches that could provide lessons learned
13 for other parts of the country as well.

14 So I don't know, maybe PG&E, Sempra, if you have
15 some thoughts on what you consider would be a practice or a
16 method that has been particularly effective? Or from the
17 other side of the table anything you've seen from industry
18 that is worth highlighting going on here in California that
19 others could learn from?

20 MR. O'DONNELL: Okay, so when you meet with your
21 colleagues right, and you do, what are the things you're
22 excited to tell them about that's working? And so if I can
23 recast your question that way?

24 MS. HAINES: Well, I think Art kind of touched
25 upon this earlier about bundling, seeing hot spots.

1 You know, most of the utilities now are using a
2 geographic information system to look at their system in a
3 whole new way to visualize their system where they weren't
4 able to visualize before. And I think a best practice is
5 to use that system to get the data, the leak data, on the
6 system and be able to visualize where the hot spots are in
7 a system. And correlate to and decide whether or not you
8 should invest in replacing that pipe or you should go out
9 and repair that one leak. Where if it's state-of-the-art
10 pipe already then you go out and just make the repair. But
11 if it's not state-of-the-art pipe then you bundle that work
12 and you go replace it.

13 I think that is the best effort right now to
14 really start moving toward permanent tightness of a system
15 is to make good decisions on whether to invest in
16 replacement of non-state-of-the-art pipe, or make the
17 repair. And that is utilizing this new technology and
18 getting that data into that technology quickly where
19 somebody can assess it and make those decisions.

20 And it's something that is fairly new, within the
21 last I'd say year, that we're finally able to start
22 utilizing the GIS system on how we need to utilize it.

23 MS. COWSERT: I'd agree with that. And I would
24 add on the application of leak detection technologies that
25 are able to detect more leaks, smaller leaks. And so you

1 combine the detection with the overlay of information, the
2 kind of looking for clusters or bundles of leaks, and
3 addressing those aggressively if you're looking at vintage
4 or non-state-of-the-art type pipe. And going out and doing
5 capital replacement of that work rather than repairs.

6 And that actually -- the concept of upgrading
7 systems is something that is being performed by many
8 distribution companies within the country. The application
9 of new leak detection technologies is kind of an emerging
10 best practice.

11 MS. HAINES: I also think bringing in other data,
12 the dig-in situation. Where we're having dig-ins is a huge
13 issue for any natural gas system, third parties hitting our
14 system.

15 And right now there's not a lot of folks that are
16 taking the USA tickets that people are calling in for and
17 porting that over to their GIS system. And then taking in
18 the transponders from their vehicles and porting that into
19 the GIS system to see where the people are, to go do random
20 audits on high-risk areas. And using the GIS systems build
21 algorithms to look at areas where there's high risk. If
22 somebody hit that line it could eliminate 23,000 customers
23 right away or if it's a high-pressure line that we didn't
24 know was there.

25 I think that utilizing this big data again and

1 bringing that into a workable format where we could do
2 better analysis on threats to the system, I think is a huge
3 area that we really haven't fully explored. And half the
4 time, people don't call the USA ticket. So the people that
5 hit our system, half the time they don't follow the law,
6 essentially.

7 And there's a theory that we should be having
8 better enforcement to go after these folks, but a lot of
9 these folks are homeowners. They're just clueless about
10 what's going on. Or they're just bad actors. And if
11 they're bad actor contractors we should be calling our
12 state agencies that oversee contractors and say, "Hey,
13 these people are not doing what they should be doing."

14 But we should be utilizing our GIS to as much
15 power to go after, and identify threats to the system more
16 than we have in the past, and get the data quickly into the
17 system through automatic data collection means. I think we
18 still are too dependent on paper and inspections in the
19 field and things like that.

20 Also, you know, there's opportunities to get the
21 public involved and engaged. You know, there's only so
22 many of the utility folks that can run around and check
23 them. But we need to do a better job of getting the public
24 involved in helping us find these illegal excavators that
25 could be hitting our system. I don't know if putting out

1 an app that gives them a Starbucks gift card or something
2 if they find somebody. Something to get more people that
3 have eyes on the system to help us find illegal excavators
4 that could be hitting our system and creating significant
5 integrity problems and safety issues for the public.

6 MR. O'DONNELL: Maybe they could just get the
7 gift card for calling in the number? It could save money
8 in the long run.

9 MS. COWSERT: Right, incentives.

10 One other thing I wanted to add on the concept of
11 dig-ins and the methane emission component of that, is a
12 best practice that we've instituted that's starting to
13 spread to the industry is tracking our shut on the gas
14 time. So when we do experience a dig-in there is
15 opportunity for gas to blow for a period of time before
16 we're able to actually shut it in. So we started tracking
17 the time it takes for us to actually do that for both main
18 and service dig-ins.

19 So the complexity of the work is different if
20 someone hits our distribution main or transmission main,
21 versus hitting a service line. But we do track that now
22 from the time we receive a call about damage to our
23 facilities to the time that we respond in the field and are
24 able to shut off the gas.

25 And so that tracking that and trying to improve

1 on that time helps us reduce methane emissions as well.

2 MR. O'DONNELL: Okay. We have five minutes left.
3 Is there another question waiting? Win, did you have
4 something?

5 MR. SETIAWAN: Win from ARB. My question is to
6 the industry regarding the cost effectiveness of best
7 practice.

8 Do you think, just looking at the amount of gas
9 saving is it enough in this case or do you have to take
10 into account damage caused by the gas released into the
11 atmosphere? Given the fact that you can pass along your
12 investment to the rate payers, you would try to convince
13 the rate payers this is good for the environment, good for
14 their own health.

15 And second, after you convince the rate payers,
16 they usually would like to track the amount of money that
17 they already spent, whether industry would be transparent
18 in this case, how their rate payers money have been spent
19 to reduce emissions?

20 MR. O'DONNELL: Okay, so that's a question that
21 goes to social costs and the cost-benefit analysis, which
22 we have a hard time dealing with and also accountability.
23 So who wants to take that on?

24 MS. COWSERT: Maybe I'll start, so I guess from
25 my perspective cost effective in the realm of a utility

1 doesn't necessarily just mean that the cost associated with
2 saving gas is all that we're going take into consideration
3 when we decide whether or not we're going do something to
4 reduce methane emissions. I think it comes in to play
5 where it has to be agreement among the stake holders
6 involved in a rate proceeding to determine what the
7 additional benefit from a societal perspective is and what
8 rate payers are willing to pay for that.

9 So I would argue its not simply the cost of gas,
10 but something probably a little bit more than that, that we
11 would take into consideration. But that would have to be
12 agreed upon through that proceeding. So we would make a
13 proposal of what we think is reasonable and what we think
14 is affordable from a rate-base perspective. But then that
15 would clearly be adjudicated and visited by all the variety
16 of stakeholders who might have a say in that.

17 So that's my perspective.

18 MS. HAINES: Yeah, I have to agree with
19 Christine.

20 I think we can't just limit ourselves to the cost
21 of gas, especially now with gas so cheap now. But I have
22 to tell you that it's very expensive to get reductions on
23 the distribution system. And that our customers, our
24 interveners, are going to basically tell us what they can
25 tolerate in terms of energy rates going up and things like

1 that. So I think we'll get that loud and clear when we do
2 propose our reduction ideas. And we'll get an idea of what
3 interveners will tolerate in terms of how much they're
4 willing to pay for that.

5 Right now just eliminate our backlog I think it
6 was like \$33 for an MCF. An MCF which is a 1,000 cubic
7 feet of gas roughly, is going for probably \$2 to \$3 right
8 now. And so already the cost to implement that reduction
9 in our backlog is an order of magnitude greater than the
10 cost of the gas itself.

11 So are we going to get funded for that? Are the
12 interveners going to be okay with us going after that gas?
13 I would hope so, but that's not really up to us. We put
14 out what it's going to cost and what we think is the best
15 way to do it. And we'll find out whether or not our
16 interveners are going to say, "Yeah, we're okay with that."

17 MR. O'DONNELL: NRDC was a pioneer of using
18 social cost factors in energy efficiency cost benefit
19 analysis. Do you have a position in this case?

20 MS. MORDICK: I mean I don't know that I have
21 much to add other than yeah, obviously we think
22 incorporating social costs of carbon into rulemakings is
23 incredibly important. We're not good as a society at
24 quantifying benefits, so yeah.

25 MR. O'DONNELL: One of the surprises to me in

1 becoming a regulator is that I always thought that if the
2 regulator tells a utility to do something, then we have an
3 obligation to give them the money to do so. That's not the
4 case. Especially with regard to safe and reliable
5 operations of the system, we expect them to operate safely
6 and reliably, no matter how much money we give them. So
7 that's a quandary that we have.

8 We have one more question in the back. Yeah,
9 okay.

10 MR. SETIAWAN: Well, yeah I think my second
11 question got answered.

12 MR. O'DONNELL: I just answered that one. That's
13 accountability.

14 MR. SETIAWAN: Oh, yeah

15 MR. O'DONNELL: They have to do it anyway, all
16 right? And prove it to us.

17 One more?

18 MR. HOU: Hi, Yu Hou from the Energy Commission.

19 Going back to the comment about threshold, and I
20 think I just will make a comment and see what are your
21 thoughts on that, it's also besides the percentage -- you
22 know, we're talking about 2 to 3 percent throughout our
23 whole system due to the emission rate -- there is also the
24 actual amount. Because if you are able to reduce to 2
25 percent or 1 percent, but your total cost of consumption as

1 a nation went up twice as much and the impact is the same.

2 MR. O'DONNELL: Okay. I'm sorry, I don't
3 understand the question there?

4 MR. HOU: I'm just going back to previous
5 comments on what's the threshold, because should we look at
6 a total emission amount annually, you know, maybe from
7 inventory. Or because of the percentage like what I said,
8 that if your total consumption rate went up, even if you
9 reduce the percentage, you will still have a similar
10 climate impact.

11 MR. O'DONNELL: The Commission is currently
12 grappling with the issue of how one sets targets and how
13 one enforces those targets in what we're looking at.

14 So if we have a grand goal articulated through AB
15 32 of 40 percent emissions reduction from one point to
16 another point, does that mean by company, does that mean by
17 industry, does that mean by component? How do you segment
18 that out? And we're still trying to deal with that.

19 As a percentage it's a little bit more difficult,
20 because again it's you're looking at aggregated figures and
21 that doesn't really help you identify where you can do
22 those savings. It's a little bit like trying to reduce
23 line losses on the electric transmission system from 6
24 percent to 4 percent. Well, you can do that, but you have
25 to know exactly where to apply your technologies and your

1 practices to do that. And that's what we're really more
2 concerned with is exactly where. What's the surgical way,
3 because that's how you reduce your costs, rather than
4 trying to have a grand emissions reduction?

5 So yeah we can live within a 40 percent reduction
6 as has been articulated, but we have to figure out how to
7 get there. And that's really the more important and more
8 difficult work I would think.

9 All right, I'm going to close it here, because we
10 are a couple of minutes over. I want to thank our panel
11 very much for the participation and the insights that they
12 brought to us.

13 And I want to thank you for your questions and
14 for your attention. (Applause.)

15 I want to thank the conference organizers, our
16 three sister agencies as well as the individuals who worked
17 very hard to make this happen and all of the vendors, all
18 of the presenters, everybody involved, the guys that are
19 out there waiting for your business when you need to go to
20 the taxi stand and to the airport. Thank you all very
21 much.

22 Elizabeth is coming back.

23 MS. SCHLEEHL: Hi, I'll be quick, because I know
24 this is at the last, but I just wanted to sum up what I've
25 heard over the last few days and just kind of go give a few

1 takeaways and what we're going to do next. And this is
2 just what I'm taking away from this, obviously not what --
3 I haven't talked to the CEC or the PUC about that.

4 I just want to throw back up the objectives here
5 and I wanted to thank everybody, because I think all the
6 presenters and all the conversations we really have reached
7 all of these objectives. I think we've had a really robust
8 conversation on the science of life cycle emissions. We
9 have looked at where some of the gaps are. And I think
10 that will help inform us on where we're going from here and
11 that sort of feeds into the last one of informing future
12 policy discussions on the next steps.

13 I'm not going to go through all of my slides, but
14 I did want to hit on a few things. I think one thing we
15 heard a lot was a tiered approach to emission research is
16 important. And that's something that we'll take away from
17 that. We have that effort and we'll continue that effort
18 looking at some of the work with the CEC on flights, on the
19 hot spots analysis, our tower work as well as our bottom up
20 work.

21 Integrating high emitters is important and we are
22 starting that process in some of our leak detection work
23 and component work.

24 On sort of the emission sources we've heard that
25 fat tail distribution is very important and that tank

1 emissions are important, not that everything else isn't,
2 obviously those are also important but that is one thing
3 that I heard coming out of this as well as imported natural
4 gas and the leakage rate associated with that.

5 I think that's come up during the panel
6 discussions. It's come out during various parts of the
7 conversation. And that's something we've been thinking
8 about and I think we'll continue to think about and watch
9 what's going on, on the federal side of things.

10 Finally a couple of other things, detection
11 technologies, as we've seen outside and downstairs today
12 there's a lot of technologies that are quickly evolving.
13 And we will be following those and figuring out how can we
14 incorporate those into our future efforts.

15 And I think the big data analysis was really
16 interesting this morning. And that can be useful for
17 determining our emission reduction opportunities as well as
18 linking science and data, how we'll integrate that into the
19 process I think will be interesting. I still haven't quite
20 grappled with how we can integrate that in kind of a
21 regulatory process. Maybe it is just something that
22 utilities may find useful as all of this new data is coming
23 in from (indiscernible) and from various different places.

24 So those are some of my takeaways. And just
25 quickly on the next steps we're obviously, all three

1 agencies are continuing our efforts, there's a lot of
2 research going on in this. And we'll continue those
3 efforts. A lot of our efforts have been mentioned. We'll
4 also continue following the detection technologies and
5 we'll be doing upcoming research as well that has been
6 mentioned.

7 After meter in homes, I think any work and
8 especially hearing some of what has been discussed on this
9 panel and any interactions we can have with the data you
10 might have to inform that, I think would be really useful.

11 And then one thing that we're excited about is
12 the life cycle model that we're starting very soon. And we
13 will continue stakeholder discussions on that and outreach
14 on that, so look for that.

15 And finally, as I mentioned earlier monitoring
16 the federal actions that are going on and seeing if that is
17 getting to some of the imported natural gas emissions.

18 So those are some of my takeaways in the next
19 steps that we're going to do here at ARB. And I think
20 you'll -- I would like to invite you to continue to stay
21 involved in our process, the PUC process for the
22 transmission distribution side, there's a lot of good
23 information coming out of there. And also CEC work and all
24 the work that's going on.

25 So that's it for me. I just want to thank

1 everybody. This has been really useful and a great
2 discussion, so thank you very much.

3 And I think we actually do have to open it for
4 public comment. So for the IEPR CEC process, if there's
5 anybody that has comments I think you were supposed to fill
6 out a blue thing, so I'll turn it over to Kathleen.

7 MS. KOZAWA: Thanks, Elizabeth.

8 I don't know if McKinley Addy, are you still here
9 -- okay, you are, you did sign up to speak. So go ahead
10 and come up to the microphone, thank you.

11 MR. ADDY: Thank you. I don't know if CEC staff
12 is still here, but for the purposes of the IEPR proceeding,
13 my name is McKinley Addy and I'm the Vice President of
14 AdTra.

15 (Brief pause to fix audio.)

16 All right, so I'm a Vice President of AdTra and
17 our company is a virtual integrator of low carbon, high
18 efficiency technologies at scale, to foster the deployment
19 of low carbon solutions, develop and deploy technologies
20 and projects. We helped recently to develop two new heavy-
21 duty natural gas engines for trucks that are rated at 450
22 horsepower and 525 horsepower.

23 I appreciate the opportunity to comment on the
24 IEPR proceeding. The topics discussed in the last two days
25 cover a lot of the topics that the IEPR proceeding will

1 cover. And I'd just like to link the information from the
2 last two days to the low carbon transportation natural gas
3 fuel use in the importance of California's transportation
4 future.

5 You know, four years ago methane leaks were
6 raised by the Environmental Defense Fund when there was a
7 question about the potential benefit from low carbon
8 natural gas trucks. We have shared this concern that EDF
9 raised at the American Trucking Association's Summit in
10 Washington D.C. And this was going to be an issue sort of
11 on the horizon in the CEC and (indiscernible) pay attention
12 to it. So it's sort of good that four years later these
13 agencies are paying attention to this.

14 We are pleased to know that efforts are ongoing
15 to collect and improve data sets, to better quantify
16 methane leaks through multiple methodologies. And with new
17 regulations and leak reduction targets at the state and
18 federal levels, information that the workshop developed
19 suggests that leak rates might be in the range of .8 to 2.4
20 percent and these are trending in the viable direction. I
21 think Adam Brandt's research paper about two years ago
22 suggests a threshold of 3 percent is desirable, others have
23 looked 1 percent.

24 We note that with more efficient natural gas
25 engines such as what our company and our colleagues are

1 developing, combined with reduced methane leaks afforded by
2 several technology solutions discussed, the low carbon
3 benefits of natural gas trucks remain also or by methane
4 blends.

5 This is important, because the transportation
6 natural gas use in the truck sector is a path to achieving
7 California low carbon fuel standard targets and the state's
8 alternative fuels (indiscernible) goals as well as Governor
9 Brown's petroleum reduction vision.

10 There are two feedbacks to the Energy Commission
11 for the IEPR proceeding is that it is important for CEC, in
12 the IEPR update, to maintain consistency with earlier
13 transportation natural gas scenario outcomes from the LCSF
14 updates and the state oil fuels plan.

15 I recommend that CEC staff's active involving
16 with the Air Resources Board's effort in the development of
17 the natural gas version or component of the Op-G (phonetic)
18 model.

19 MS. KOZAWA: Thank you, for your comment.

20 Any additional comment for CEC workshop?

21 MR. LEYVA: Jennifer, are there any questions on
22 the line, on the phone?

23 OPERATOR: No, I'm showing no questions.

24 MR. LEYVA: Okay. Thank you.

25 MS. KOZAWA: Okay. With that, I'd like to

1 conclude the public workshop portion of today. And we
2 thank you for sticking around the whole time for the
3 symposium. (Applause.)

4 (Whereupon, at 3:55 p.m., the Joint Agency Symposium
5 & Workshop was adjourned)

REPORTER'S CERTIFICATE

I do hereby certify that the testimony in the foregoing hearing was taken at the time and place therein stated; that the testimony of said witnesses were reported by me, a certified electronic court reporter and a disinterested person, and was under my supervision thereafter transcribed into typewriting.

And I further certify that I am not of counsel or attorney for either or any of the parties to said hearing nor in any way interested in the outcome of the cause named in said caption.

IN WITNESS WHEREOF, I have hereunto set my hand this 22nd day of July, 2016.
